TO OUR READERS.

(*From an unpublished work.*)

"George, how many years have you driven 'The Success?'"

"More than twenty, my Lady."

"Are you not tired of the occupation?"

"Not a bit, my Lady. You see, Robert is always about the coach, and when I and my little woman want a holiday, he takes the ribbons. There is no end of change in coaching. Although we never turn off the old horses, and we drive steadily, yet they die off, and then we have to draft in new sound ones. Then opposition coaches start, and it 's pleasant to see how they sometimes are trying to run before us, and sometimes running behind us."

"But, George, they must take some passengers from you."

"I daresay they do sometimes, my Lady, but we never miss 'em, for we are always full, thank God, and the old passengers come back after a time, and say they are sorry they ever left us. Sometimes a new start, to make a show, takes passengers for nothing; but that, my Lady, you know, wo'n't fill the corn bin."

"Your horses, George, go as well as ever?"

"Yes, my Lady, they are a well-bred lot, and plenty of 'em; and they know who handles 'em; and we give 'em a few beans occasionally, and the passengers know 'em and pat 'em, and horses like that. Why, my Lady, some of 'em have been leaders ever since the coach started, and go over their ground as fresh as the first day they put their shoulders to the collar. Everyone says how fresh and gay 'old Bob' and the 'Kentish Cob' are still. Wonderful horses they are. And the young uns, my Lady, how steadily they keep the pace! Why, the box is as easy as an armchair. Neither Robert nor I ever used the whip since we mounted that box. Besides, my Lady, the team has travelled so long together, that they are used to one another, and Robert and I made up our minds years ago never willingly to change 'em so long as we held the ribbons of 'The Success.'"

INDEX.

ABUTILON VEXILLARIUM MARMORATUM GRAFTING, 200
Acacias, new, 249
Accrington Poultry Show, 433
Acer Negundo propagation, 220
Achimenes, and their culture, 408; potting, 177

From observations taken near London during forty-three years, the average day temperature of the week is 41.5°; and its night temperature 29.2°. The greatest heat was 54°, on the 7th, 1845, and 9th, 1852; and the lowest cold 11° below zero, on the 4th, 1867. The greatest fall of rain was 1.00 inch.

THE NEW YEAR'S PROMISE.

DID you ever through an open door overhear a little child saying its lessons? I do not mean one so far grown as to be dignified with the name of boy or girl, but a child, a little child, a trusting, fully-confiding little thing, such as the Great Master took on His knee and declared that "of such was the kingdom of heaven"—one that as yet its mother could not on any account allow any other one to teach; and as to its lessons they are but half play, a little verse or two, a merry running rhyme which is repeated and acted as well. Now, if through an open door, or window, you, unseen, have overheard such a little one so doing, you have stood, and paused, and listened with delight unfeigned to the silvery voice so new, so clear, so young, and you have thought, What a sweet beginning of life! No child this cuffed by cruel hands; no dirty, ragged, gutter-child, but all that should be. What a sweet beginning of life! what a fair promise of a bright and happy future! Now such-like is the beginning of this year, not as last year, with war near us. No cruel siege of a great city, no starvation within of woman and child, but all pleasant, all promising; peace at home and abroad; the nation's love roused to the nation's Sovereign and her son; the old English Oak shown to be sound at heart still, the old hereditary instincts true as ever, and the national heart still human and humane. The year opens with all Englishmen having felt and feared together, and so now bound closer together. The new year comes to us, and it seems to give a fair promise of happiness, and like the little child's voice, it is young, and new, and sweet. What it may prove none can know until its end, but this we may say, it promises well.

Now let me note some current or recently current matters which bear, or have borne, upon us as readers of "our Journal." There is said to be a tendency in this age for wealth to become centred in a comparatively few, and, on the contrary, the many to become very poor, so that rich men will grow richer, and poor men poorer. Of many sources of wealth I will not speak; but of one, the old source—land, I will speak briefly. Thirty years ago, and further back, the poor man had a better chance, because commons were not enclosed, and each resident had "a common right." In the part of England I lived in when a boy (the fens of Cambridgeshire), commons were according to their name, common in number and in character, and on them the poor man could graze his flock of geese, and let his sow and her pigs take their run. Commons are now things of the past, and the poor man is a loser. This should be remembered by those who have landed property; and if the best of the poor are to be kept either from emigration or from removing to large towns, land must be attached to each cottage. In Edward IV.'s reign no cottage was without its four acres, and in Elizabeth's reign no cottage had less than a rood of land attached to it. The owners of land are doing well, occupiers are doing well, for if a farm be vacant there are a dozen who want it. I speak of my own neighbourhood, where it is impossible to get a farm unless by interest or favour of some kind, and often have I been asked for a recommendation.

This being so with owners and occupiers, I want to see the deserving among the lower class favoured with a few acres here and there, and a good garden always, and the land not let at what is called "accommodation price." These are times when much is done, in sickness especially, for the poor; but charity lowers self-respect, and is apt to injure, whereas help a man to help himself, and you benefit his purse and his character too. Of one pleasant day connected with benefit to the poor which I spent last year I must briefly prattle.

The late Prince Consort founded an association for improving the condition of labourers and others living in Windsor and twelve surrounding parishes. It helps in this way: Prizes of £1, £2, or £3 to the labourer, or artisan, or his wife who has brought up a family in sober, honest, and industrious habits, without parish relief, except in cases of sickness; also to the widows of such. Prizes of a similar kind to families distinguished for cleanliness and tidiness of house and person; also to well-conducted servants who have lived longest in the same place. To young persons who have kept their first place of service for the longest period (not less than three years). Prizes, too, to the best cultivators of the gardens and allotments, being persons of honest, sober, and good moral character. Prizes, also, for exhibitors of the best collection of vegetables, or the best specimen of needlework, cottage handicraft, and economy. Now, it so chanced that I was invited by one who takes great delight in "our Journal," and reads its pages every week, to be present last July at the annual meeting of this Society, held in the Home Park, Windsor. No pleasanter and more truly joyous scene can be imagined. The Home Park, which lies just beneath the grand old Castle and its terrace, was opened to all. Crowds of healthy Berkshire labourers, their wives and daughters, were present; crowds, too, of ladies and gentlemen, military uniforms, so Windsor-like, and music and tents filled with flowers and fruits, and works of needle, and knife, and tool. Right pleasant was it to see the prizetakers—226 in all—receive the rewards of their good conduct, thrift, or skill from the hands of one of our Princesses, who graciously stepped down from the platform on which she stood, when an old woman of eighty-three and another of seventy-seven received prizes for their needlework, so thoughtfully sparing their tottering steps. Then there were three huge Guardsmen who received prizes for their—mark it!—needlework—bedcovers and patchwork tablecovers! When I saw all this, princes, nobles, clergy, military men, all busy and happy with doing good to the poor, I had two thoughts—one, Such things make England strong; the other, Why should not such associations be in every neighbourhood?

There is also another matter connected with conferring benefit on the poor which I must mention. I have noticed during the year the Children's Flower Show at

the Victoria Docks, and Mr. R. Fish followed soon after with an admirable article entitled "Importance of an Interest in Gardening and Natural History to the Young." If that paper happened to escape the eye of anyone interested in the improvement of children, let me state that Mr. Fish's remarks are to be found in the number of our Journal for July 27th.

But yet the other matter I was alluding to, I mean another scheme for the good of poor children. It seems that Mr. Ruskin, England's great art critic, who has shown in his writing how marvellously pliant and powerful is the English language, has given a small space of ground for a play-place. Our forefathers would have called it a pleystow, or plestor, *locus ludorum*, for the poor children in one of the densely-peopled parts of London. It is but a small space, but when it had been cleared of rubbish in came the London children and, with as keen enjoyment as our rural ones, mounted the seasaws, and held on at the swings; and we are told that gradually the tone of the children was improved; the manners, bad indeed at first, grew better. The presence of ladies among them began to tell. Miss Hill says, "We took them flowers, acorns, seaweed, pictures, beads, all marvellous new things to be seen and handed round. We taught them games, and they played them. Many an hour have I spent teaching them to make daisy-chains, or to thread beads. Our ground was in one of the worst courts of the neighbourhood, and the dirtiest, wildest children flocked in without restriction. Now, gradually, instead of destroying all that comes in their way, they actually delight to watch and water our five trees which we have planted, and our creepers. The civilising influence has partly been from the fact that the children are withdrawn from the terrible influence of the streets and courts, and partly from the fact that they are gradually placed amongst pretty things that want care." Miss Hill goes on to state that they have one annual gathering, on May-day, and a Maypole, and many friends are there to meet about four hundred children.

Here, surely, is a blessed work. Here are "sweetness and light" for poor things brought up in the midst of filthiness and darkness. Would that there were many such playgrounds scattered over London. The Parks are too far for many. Children must play. John Wesley, good man as he was, made yet a great mistake in his arranging each hour's work for each day in his institution for children, and yet not to allow a play hour. This may be excused in him, for he was a childless man. Children must play. Last summer I saw ragged urchins playing horses in St. James's Park, and if such have no wholesome play they become precocious, impish, little things, looking upon all people as their natural enemies, full of thief's slang, mocking in gesture, and filthy in converse. Whence all the wild ideas of the Communists? from the fact of their working all their days in town workshops, shut out from the pure air of heaven, and from the sight of tree and flower. If we cannot take the town children to play in the country, then the next best thing is to provide, as Mr. Ruskin has, play-places for them in the town. He has done a patriotic act, and a christian act as well.

As to gardeners and gardening, and I hope gardeners are prospering, man's first trade is among his best still, so far as enjoyment goes, if there be in a gardener a true and loyal love for his profession. I have sometimes thought when passing through show tents of beautiful flowers, and fruit, and vegetables, that there is a higher aspect in regard to taking prizes, which is, perhaps, too often forgotten. Not alone is there a wholesome rivalry, not alone do prizes keep men up to the mark, and striving beyond their present mark, but think of the patience needed to obtain a prize. Think of the care and forethought, as well as pains and patience; and all these improve and raise a man's character. Look at that prize flower; it grew not like the Buttercups, without any tending. Look at those Grapes, amazing in size of bunch and berry, and rich and beautiful in colour. Think of the hours out of bed in the cold frosty nights that the gardener had, and the skill he has shown, and if shown, the skill he is possessed of. In regard to prize birds it is the same. No idle, no unskilled man takes the cup and the money. What patience a breeder has! what management in crossing! what disappointments, often at the produce being so different to what was hoped for!

Now, all this patience, &c., is good for people; their minds are thus benefited and disciplined. Besides, how such things keep evil thoughts out of mind, and evil feelings out of the heart! The unoccupied man whose mind and heart are fallow is the one most open to evil. Then, also, if care, and pains, and skill not always issue in success, let the unsuccessful remember that a law of compensation runs through Nature. I often have seen this in my beautiful Elms in the park near me. I love to see their giant arms stretching out at right angles to their trunks. How noble they are! how handsome they make the trees! but they grow heavier and heavier, and some windy day in full leaf the great outstretched arms fall to the ground, and the tree stands a maimed giant. But a few years and tufts shoot around the great scar on the stem, and a few more years and graceful branchlets have grown out, and the tree is again beautiful. This law of compensation runs through Nature, and an honest man, even having failed, finds yet a blessing follows in some unlooked-for way, perhaps.

In regard to reports of poultry shows, I think an unreasoning and unreasonable complaint is often made about their not entering enough into details. But it is after all a narrow subject; the field is not large, and extraneous matters, special, perhaps, to the place where the show is held, being introduced can alone make variety and make an article readable, and what is not readable is not worth the cost of printer's ink.

An objection I remember was once made—indeed, more than once, against those writers who prefer using a *nom de plume* instead of their patronymic, and we were told that we were ashamed of our names. "Not a bit of it," say I. At the same time I think this, that it would be well that a writer should adopt a designation which gives an idea, if not of who he is, yet of what position he holds. Hence, I object to mere initials, which do not even give the sex of the writer. Those who receive numerous letters from strangers frequently get some from those who only sign with the initial letter of their christian names. These are sadly puzzling. Thus, I receive a letter in a good bold hand stating that the writer will call upon me, and this letter, say, bears the signature, "J. Smith." Is it John Smith or Julia Smith? "that's the question." Is it to be a study guest or a drawing-room one? Then, suppose the letter requests an answer, is it to be addressed John Smith, Esq., or Mrs. Smith, or Miss Smith? The handwriting alone is not sufficient, for now ladies write so much like gentlemen, only, not unfrequently, much better. So, I think, initial writing is always wrong, private or public. Ladies are the greatest offenders in letters; so if a woman is named Susannah or Kerenhappuch, I hope she will write it in full—it is her godmother's fault, not hers, that she was not named Edith, or Ada, or Ethel, or like angel-sounding names. So I venture to hope, that if any lady or gentleman is burning to attack or praise me in these columns, they will not adopt merely initials. Of course, those who have long written under initials it is too late to mend. Yet if "Y. B. A. Z." had written under "Country Surgeon," we should have attached great weight to any remedy he had proposed for fowl-disorders.

Something has during last year been said about poultry prizes for the working classes. I hope the subject will not wholly drop out of sight. As a life-long pigeon-fancier let me notice, that as Antwerps, the real working homing Carrier, have come to the front, and taken a place at our shows, and people have delighted to gaze upon a pen of birds with a notice on their pen of their performances, so I think the other real bird of the air, as wonderful for his performances in the air as the Antwerp, will also come to the front, and appear at our shows—I mean the high-flying Tumbler; his aërial gymnastics are marvellous, and he is as worthy a bird as the Antwerp. I should like to see cages of such birds shown, good in feather and form, with truthful accounts of the hours they have flown. I believe in Birmingham an effort is being made in this direction, and pretty and useful birds under the name of Rosewings, Redbreasts, Whitesides, &c., have been exhibited; but as I have never seen any of them I cannot speak from personal observation. Probably the Muffs will be reduced to mere grouse-feathering, and the Tumbler form, in its dapperness, be attained—better still if the legs were quite clean. The clear coral legs and feet, as also the pearl eye, best suit the pretty Tumbler form. May, then, flying Tumblers, most interesting birds as they are, become more general favourites.

Another kind of show is growing in popularity—I mean Cat shows; and lo! it is discovered that not ladies, maiden ladies only, but some gentlemen love and admire cats! Who knows but, as the cat is becoming an animal of points and properties, that choice breeds will be kept in aviary-like buildings, and anxious visitors will appear, asking for permission to visit "feliaries?" Well, poor puss has had many a stone thrown at her, and it is fair there should be a turn in her favour. She

has mourned for generations over countless litters of drowned kittens, and grudgingly allowed one live one; perhaps whole litters will gambol about her in the future, and gratify her motherly instincts. Who can tell? A cat helps to make a home; and a wise man said, "A servant is not worth having until she talks of our cat." Pigeon-fancier and ignorant blackguard used to be associated ideas with some people, yet how untrue that association would now be.

A man of great intellect, though I cannot agree with one of his books, Mr. Darwin, was thus spoken of in the *Saturday Review* of last March: "When Mr. Darwin was pursuing his inquiries into the origin of species he was known to one class of mankind simply as a pigeon-fancier. They supposed, it may be, that his ambition was limited by that which formed its more immediate goal, the production of a pigeon with a beak a tenth of an inch longer (!) than its ancestors, or with rather a more brilliant iris on its neck (!)" It is quite clear that the reviewer is no pigeon-fancier, but utterly pigeon-ignorant. Still, when men of Mr. Darwin's calibre delight in fancy pigeons, it shows there is much in them to cause intellectual pleasure. A modern authoress, of whose mental powers no one doubts, Mary Russel Milford, thus writes to Miss Barrett, afterwards Mrs. Browning, "I love to see my tame pigeons feed at the window, and the saucy hen tap at the glass if the casement be shut. She likes to come in and to sit on the innermost ledge of the window-sill, and listen and turn her pretty top-knotted head to this side and that while I talk to her. This pleasure I owe to you, having taken to the home-loving domestic pigeons as a rustic imitation of your doves, and they blend well with my flowery garden." Thus we have the author of "Julian" and "Rienzi" loving pigeons, and Mrs. Browning, the most learned of modern ladies delights in keeping doves. But go further back to another woman, a great historic character, Mary Queen of Scots; in a letter dated 1574, she writes to friends abroad, "I beg you procure me pigeons, red partridges, and hens from Barbary. I intend to endeavour to rear them in this country, or to feed them in cages, as I do all the small birds I can come by—a pastime for a prisoner." Thus how far diffused is a love of pet birds, and how much pleasure they afford! We of this Journal help to foster these gentle tastes. No advertisement on our pages reads like this—"Fox-terrier pups, bred to murder." Cruel-sounding, certainly.

And now to draw near to a conclusion. The past year saw one of our staff pass away, one whom even the soft air of Devon could not keep in life—I mean Mr. Woodbury. I knew him not in person; his hobby is not mine; but I read enough of what he wrote to know that he was an able and a kindly man. Peace to his memory! May the honey bee he loved so well make its solemn music over his grave!

The New Year promises well. May it fulfil all its promise to all who write or who read our pages. I know of some who not only read but long for the next number to read on. May our bark float this year in smooth waters, with a bright sun and a favouring breeze, and, whether to those on board or those who look on, may the new year be a healthy and a happy year, and more than fulfil its promise.—Wiltshire Rector.

PRUNING LATERALS.

By M. J. Van Hulle.

As a rule, pruning-time still falls within the months of February and March. In this article we would remind our readers that the winter, unless it be frosty, is by no means an unfavourable season for pruning, and experience has taught us that October or November is a more favourable time still for the purpose. In either of these cases the gardener will obtain at least one advantage, and that is his work will be considerably lessened in the spring, when, as everyone knows, gardeners have enough to do. By completing the pruning at this period the laceration of the trees at a season when the sap is beginning to flow, and which should not be inflicted unless they are in a very vigorous condition, is avoided.

But, whatever be the pruning-time, we would particularly advise persons in their passion for beauty, their regard for symmetry, or in their devotion to the rule which says "that the side branches should be pruned as short and as near the mother branch as possible," not to fall into the mistake of cutting the laterals, which either bear or promise to bear flower-buds, too short. He who scrupulously pays attention to the above-quoted advice, continues but too often to respect it for a number of years, when he finally attains his object; but on reflecting that this time has been spent in forming the framework of the trees, and that no fruit has been gathered in the intervals, he must confess that it has cost him dear. As for the Peach, in which the bearing-wood is the chief thing, there are reasons why it should be pruned a little shorter, but we, nevertheless, think that it is better not to push this practice too far. There is a greater probability of having fruit on a branch with from 8 to 10 inches of wood left untouched, than upon the same branch if shortened to the fourth or fifth bud lower down. The bearing-wood must not, however, be forgotten.

It is more especially in the case of the Pear that we would recommend that the laterals should not be pruned too short. Certainly these, if woody and too strong, ought to be cut to the base or well broken as far as the sixth or seventh bud, or still more—breaking to the second or third bud would only give rise again to undesirably strong shoots—but all the other branches, although they might not be "spurs," provided they resemble these up to a certain point, should be left untouched, be they 8 inches in length or even more. We are aware that it is a grave infringement of the rule, still it is really not only a question of shape, but also one of fruit. The unpruned laterals nearly always bear flower-buds at their ends, and as the branches must of necessity bend beneath the weight of the fruit arising from these, the consequence is that there will be fruit at the lower part much sooner on the "spurs"—spurs as fine as those of any tree treated on the short-pruning system. Once these spurs have come into being, they are sure to grow again.

Thus it is that the desired object is attained; in fact we secure the fruiting-wood very short and as nearly as possible in the condition for forming the framework, more surely and sooner by pruning the lateral long than by pruning it short; and with this noteworthy difference—that in the meanwhile a supply of fruit has not been wanting.—(*Cercle d'Arboriculture.*)

MADRESFIELD COURT GRAPE.

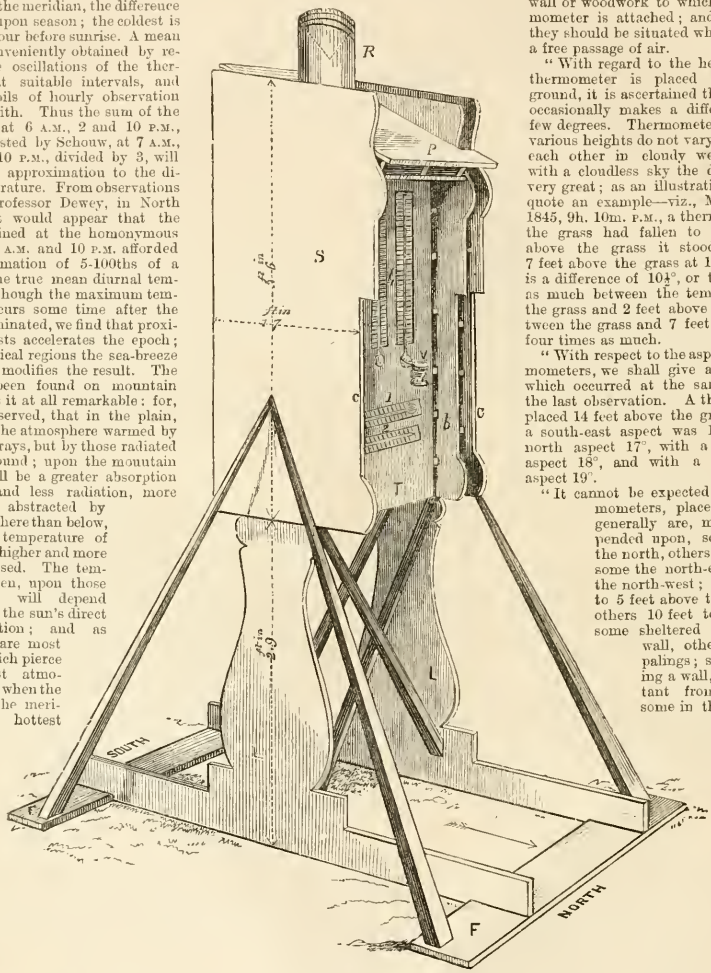
The following information may be useful to "J. W." I have not grown this Grape yet, but having seen it in very fine condition I obtained two plants of it, intending to grow it both in the early and late vineries. I am now assured that it is not at all adapted for late vineries, as it will not keep after Christmas. Indeed Mr. Stevens, of Trentham, exhibited excellent examples of it at South Kensington last year, and it was stated on his authority that it was not likely to keep after that date. I also saw it fine in Scotland in September last; but in a communication received from one of the best Grape-growers in that country, dated December 9th, the writer says, "Madresfield Court Grape has all gone rotten with me, and I find it is doing so elsewhere;" so I think we ought to be cautious how we plant it in late houses. That old variety, Gros Guillaume, better known as Barbarossa, is not so much grown as it ought to be for late work. It requires the temperature of the Muscat house. It is also a noble Grape in appearance, and superior to Lady Downe's in flavour. I grow it on its own roots, and it could not possibly do better. The true Black Alicante keeps well, and is also of superior flavour. Mr. Sage, of Ashridge, took the first prize with it at South Kensington on March 1st in the class for late Grapes, beating very superior examples of Lady Downe's. Mrs. Pince's Black Muscat even when well grown, generally colours badly, and is the first to show signs of shrivelling in the berries; it is, however, very distinct, and the flavour is very rich. The following black varieties are distinct and adapted for growing in late houses—Alicante and Gros Guillaume require the most heat. Mrs. Pince and Lady Downe's can be grown in a lower temperature, but they ought to be quite ripe by the first week in September. —J. Douglas.

THERMOMETRICAL OBSERVATIONS.

[The following will supply the information asked for by "W. M."]

Variations of temperature have many controlling causes, for, as observed by Dr. Thomson, the temperature is altered by an almost infinite number of circumstances; thus, altitude, latitude, longitude, horary and seasonal periods, the presence of aqueous meteors, winds, and the physical relations of the locality—even the aspect of the horizon—whether it is rugged

or unbroken by lofty eminences, the chemical nature and colour of the soil, influence the result. Subject, however, to numerous fluctuations, we, nevertheless, observe that there are two stated periods of the day when the temperature reaches a maximum and minimum. The warmest period is generally from two to three hours after the sun has passed the meridian, the difference depending upon season; the coldest is nearly an hour before sunrise. A mean may be conveniently obtained by recording the oscillations of the thermometer at suitable intervals, and thus the toils of hourly observation dispensed with. Thus the sum of the indications at 6 A.M., 2 and 10 P.M., or as suggested by Schouw, at 7 A.M., noon, and 10 P.M., divided by 3, will give a near approximation to the diurnal temperature. From observations made by Professor Dewey, in North America, it would appear that the result obtained at the homonymous hours of 10 A.M. and 10 P.M. afforded an approximation of 5-100ths of a degree to the true mean diurnal temperature. Though the maximum temperature occurs some time after the sun has culminated, we find that proximity to coasts accelerates the epoch; and in tropical regions the sea-breeze still farther modifies the result. The same has been found on mountain tops; nor is it at all remarkable: for, let it be observed, that in the plain, not only is the atmosphere warmed by direct solar rays, but by those radiated from the ground; upon the mountain top there will be a greater absorption of caloric and less radiation, more heat being abstracted by conduction there than below, where the temperature of the earth is higher and more equally diffused. The temperature, then, upon those lofty spots will depend chiefly upon the sun's direct calorific action; and as those rays are most powerful which pierce the thinnest atmosphere—*i.e.*, when the sun is on the meridian, the hottest period of the day will be at, or very soon after, culmination.—(*Elements of Meteorology.*)



To obtain accurate comparative observations and records of the maxima and minima temperatures daily, requires not only that the thermometers should be accurately and similarly graduated, but that they should be similarly exposed and similarly protected in every respect.

Mr. E. J. Lowe published some years since, in the "Gardeners' Magazine of Botany," the following judicious directions upon this subject:—

"Thermometers for comparison should all be placed at a certain height from the ground; they should all face the north (except those which are required to register the maximum temperature in the sunshine, which should face the south); they should not be influenced by radiated heat, by currents, by reflected heat, such as is communicated from an opposite wall, by absorption of heat from the wall or woodwork to which the thermometer is attached; and, in short, they should be situated where there is a free passage of air.

"With regard to the height that a thermometer is placed above the ground, it is ascertained that an inch occasionally makes a difference of a few degrees. Thermometers placed at various heights do not vary much from each other in cloudy weather; but with a cloudless sky the difference is very great; as an illustration we shall quote an example—viz., March 13th, 1845, 9h. 10m. P.M., a thermometer on the grass had fallen to 4.5°, 2 feet above the grass it stood 15°, and 7 feet above the grass at 18.5°. Here is a difference of 10½°, or three times as much between the temperature of the grass and 2 feet above it; and between the grass and 7 feet, of 14°, or four times as much.

"With respect to the aspect of thermometers, we shall give an instance which occurred at the same time as the last observation. A thermometer placed 14 feet above the ground, with a south-east aspect was 15°, with a north aspect 17°, with a north-east aspect 18°, and with a south-west aspect 19°.

"It cannot be expected that thermometers, placed as they generally are, may be depended upon, some facing the north, others the south; some the north-east, others the north-west; some 3 feet to 5 feet above the ground, others 10 feet to 20 feet; some sheltered by a high wall, others by low palings; some touching a wall, others distant from it; and some in the angle of a high building (cool as a cellar), and others exposed to the rays of the sun at one or other hour during the day.

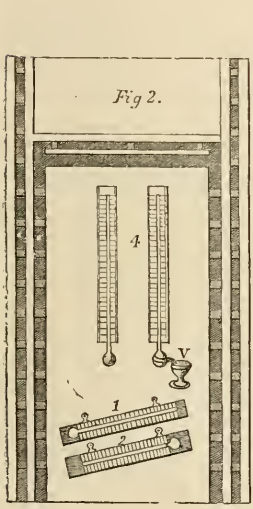
"'The Lawson Meteorological Thermometer Stand,' which we shall describe, is so arranged that it may be placed in any eligible situation; it commands a true north and south aspect; the instruments can be read off with the greatest facility, and they will be at a known distance from the ground; the instruments on the south face will have the meridian sun, and those on the north face will always be in the shade. The instrument is not costly, and were this stand universally adopted, observations, whether recorded here or at the antipodes, could

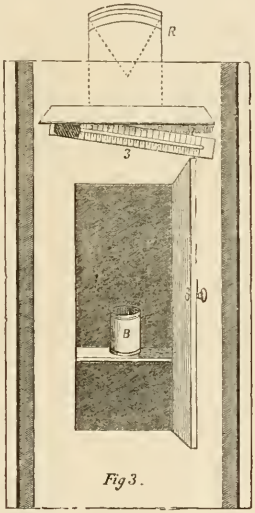
be compared with each other with far less chance of error than has hitherto been the case.

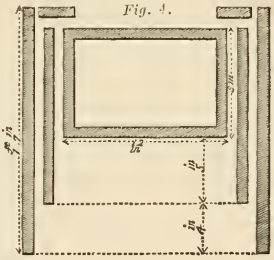
"*Fig.* 1 is a view of the stand. It is composed of white deal boards, and can be constructed by any carpenter. It consists of an oblong trunk T, 12 inches by 8 inches outside measure, to the opposite sides of which trunk are nailed boards, *b*, *b*, at the distance of three-quarters of an inch, and projecting about 6 inches from the trunk towards the north. Outside of these are nailed other thin boards, *c*, *c*, full half an inch distant, and projecting about 4 inches beyond the last-mentioned boards, also towards the north. These sides being thus multiple, prevent the sun from heating the interior of the stand, where the thermometers are placed. The top or pent-board, P, is made double, and the boards are placed fully three-quarters of an inch distant from each other, and come so forward as to overhang by a full inch. The legs, L, L, of the stand are merely the continuation of the sides of the trunk. The boards, or feet, F, F, are loaded or fixed to the ground to sustain the force of the wind. The interior, T, is blackened to prevent strong reflections of light.

"*Fig.* 4 is a ground plan, or bird's-eye view of the machine. The sides and woodwork generally are of three-quarter-inch white deal. The distance or space between the sides of the trunk, T (*fig.* 1), and the board or inner bide (*fig.* 4), is three-quarters of an inch; and the distance from that board to the outer side (*fig.* 4), is full half an inch. The narrow boards (*fig.* 4), are to be nailed, with studs intervening, to the middle board or side, and are for the purpose of preventing the sun from shining between the trunk and the sides of the stand, when near the meridian. The sides are fixed one upon another at the required distances—viz., three-quarters of an inch and half an inch, by numerous wooden studs, partially shown at *figs.* 1 and 2, about three-quarters of an inch diameter, and the screws passed through the sides and studs, fixing the whole firmly together. The whole is to be painted white, except the trunk T, which should be black.

"*Fig.* 2 is the view of the north side of the stand. No. 1 is an index thermometer to give the greatest cold of the night. The thermometer inclines, the ball end being the lowest, in order that the index, by being assisted by gravity, will move more easily. No. 2 is an index thermometer to show the greatest heat of the day; for the same reasons it is also placed on an incline, the ball being the highest. No. 4 are a pair of thermometers called the wet and dry-ball thermometers, to show the power of the air to evaporate water. V Is a vase or cistern of water for the wet-ball thermometer; it is placed on







the outside of the thermometer, to which a cotton wick is to be attached to connect it with the water, and at about the same elevation as the ball of the thermometer, in order that the evaporation from the vessel of water may not influence the thermometer on the other side, which is to be the dry-ball thermometer; for, in some careful experiments which I made with a vessel placed beneath the balls, it was found that the dry ball was lowered from 0.2° to 0.3°, which, though apparently a small error, is a serious amount in the main difference between the readings of the dry and wet-ball thermometers.

"*Fig.* 3 is the view of the south side of the stand. No. 3 is an index mercurial thermometer, with a black ball to give the greatest solar heat. R Is a rain gauge on Glaisher's construction; and B is a measure into which rain is to be poured for measurement."

For ascertaining the temperature of the soil at various depths, we recommend three tin tubes to be sunk in it in a place fully exposed to the sun, but far from a wall or other shelter; each tube to be about 2 inches in diameter, and of the respective depths of 2½ feet, 1½ foot, and 9 inches. These tubes should have in each a thermometer with the shank lengthened so as to correspond with the depth of the tube in which it is placed. These tubes should be covered over by a hand-light glazed only on the top to exclude rain from entering the tubes, but entirely open at the sides to allow of the free admission of the air. The thermometers should be well packed into the tubes with cotton to exclude the atmospheric temperature.

The importance of ascertaining for a certainty that the soil is of a temperature correctly relative to that of the air above it is demonstrated by the fact, that naturally its average temperature is always higher than that of the air. In other words, the roots on the average are kept warmer than the branches.

From observations made at Chiswick during six years (1833–1847), Mr. Robert Thompson gave the following epitome of results:—

"The hottest year as regards the temperature of the earth, 1846, afforded a mean temperature of 52.32° at 1 foot deep; and 52.85° at 2 feet deep. In the coldest year, 1845, the mean temperature at 1 foot deep was 48.95°; and at 2 feet deep 49.44°. The respective differences of the two thermometers in these hottest and coldest years were 3.37° at 1 foot

deep, and 3.41° at 2 feet. The mean temperature of the air was 51.45° in 1846, and 47.92° in 1845; the difference being 3.53°.

"On the average of the six years the earth is coldest in February, and warmest in July. The mean temperature of the air is also highest in July, but it is lowest in January. Throughout the months the gradations of temperature are not uniform. The monthly progression is as follows:—

"*Temperature increases.*

	Feb.	March.	April.	May.	June.	July.
1 foot deep....	(Lowest) 3.10°		5.01°	7.32°	7.65°	2.35°
2 feet deep....	(Lowest) 2.25		4.47	6.39	6.77	3.00
Air	0.23	4.39	5.20	7.04	8.04	1.99

"*Temperature decreases.*

	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.
1 foot deep..	1.12°	4.02°	5.97°	5.59°	6.04°	1.62°	1.07°
2 feet deep..	0.42	2.91	5.30	5.65	5.20	0.95	1.45
Air	2.24	4.84	5.93	6.48	7.29	0.10	—

FORCING VEGETABLES.—No. 5.

THE CARROT.

Carrots must not be omitted from the list of the various sorts of vegetables that require forcing, as they are quite as much sought after in the spring for making-up certain dishes as any other vegetable sent to table. They are particularly sweet, and have a tender transparent flesh, with a flavour peculiar to themselves, so that it is surprising they are not more frequently cultivated. A crop of them can be easily grown by artificial means, since they do not require so much space as many other sorts of vegetables. A large crop can be produced under a two or three-light garden frame, and will last a considerable time, as it is not, like the Potato, an everyday vegetable. To grow them successfully a mild temperature only is required, consequently there is much less trouble in applying dung linings to keep-up the necessary temperature.

Unlike many other sorts of vegetables, the Carrot does not admit of being forced in a variety of ways. The old method practised for so many years has not been improved upon, nor do I think it ever can be. By it we are most certain of producing what is required as inexpensively as by any other plan. It is this: Make with dung or leaves, or both together, a hotbed of moderate thickness, and sweeten it in the usual way; select an open, airy position for the bed, and place the frame upon it when the heat begins to rise; if the weather be frosty at the time, cover the bed with 6 or 8 inches of soil, which should be moderately warmed, or else it will so diminish the heat as to prevent it rising again. I would advise that, after the frame is put on, sufficient manure be placed inside so as to bring the soil rather close to the glass; this soil should be of moderate richness and not too light. Be certain that the heat is not likely to become too strong, then sow the seed, cover it with finely-sifted soil, and press the whole firmly with the back of the spade. After the lights are on regulate the heat by ventilation, and when the heat declines apply external linings of moderate heating capacity. When the plants show themselves admit air in favourable weather to prevent drawing, and continue this system of ventilation throughout the growth of the crop. As the plants grow, frequent thinnings will be necessary, until, at the end of the final one, the plants will remain not less than 3 inches apart. Water, of course, must be applied, but moderately at first.

If the seed is sown in the first week in January, which is, I think, the usual time, by the beginning of March the lights of the frame may be removed entirely in the daytime and placed on at night; but if they are wanted for other purposes, a mat or canvas protection, properly constructed, will answer the purpose of the lights remarkably well. There is not a great choice of varieties for forcing, but those we have are really very good. They are the Early Short Horn and the French forcing Carrot. The latter, I find, comes in a little earlier than the former, though the Short Horn is a better colour, and, I think, better in flavour. The Short Horn is the one I use, and it gives satisfaction.—Thomas Record.

AMONG THE CONIFERS.—No. 1.

In no class of hardy ornamental trees is there so much real utility and elegance combined as in the Conifers. From the time they are a foot high until the time they attain to large proportions, they are as useful as ornamental. It is in some measure owing to the very early age at which young plants of this order can be turned to account, that they are so much esteemed. A choice selection of young Conifers tastefully disposed about a flower garden in winter has an exceedingly agreeable effect, and offers many points worthy of study. Used for such a purpose, planted on lawns in single specimens or mixed groups, distributed in wild woodlands and over extensive landscapes, they are equally satisfactory.

There can be no doubt but that all the varieties worth growing appear to the greatest advantage when carefully arranged in a pinetum. This, however, can rarely be well done, as a pinetum, to be worthy of the name, should be spacious, and every part kept in tasteful order. Rather than a formal pinetum in small gardens, I should like to see the limited number of Conifers either associated with other shrubs, or arranged in pleasing groups tending to alleviate the formal aspect of those Primrose-lined turf plats not unusually to be seen. My own idea of a thoroughly enjoyable pinetum is the total absence of all formality of arrangement, and the interspersion of groups of Rhododendrons, Roses, Azaleas, Heaths, Kalmias, Ledums, Cratægus, Cytisus, Cercis, Escallonia, Hydrangea, Magnolia, Pæonia, Philadelphus, Ribes, Spiræa, Syringa, Weigela, or Pyrus. In contrast with the best varieties of these species, the Coniferæ afford a far more pleasing aspect than when seen alone, as the flowering shrubs not only conduce to enliven the scene with their blossoms, but impart greater charm to the "dark-hued Pines."

The contrast presented by Conifers of the same kind growing in different soils, is very striking and worthy of attention. Even such hardy and common kinds as the Spruce and the Larch, exhibit the influence of soil and situation upon their general appearance in a remarkable manner. Let the soil be light and sandy, or so close as to merge upon clay, but at the same time well drained, and the trees will flourish. The Spruces sending forth their pendant branches in graceful curves, tasselled with a profusion of luxuriant laterals, and tapering in all the stateliness granted them by Nature, compel our admiration and care. I have occasionally met with such trees—notably at Maresfield Park—but perfect specimens are by no means common. A remarkable difference is frequently visible in large plantations, the Larch appearing to flourish much more vigorously upon slopes and elevated positions than it does in low-lying damp soil, where it is not at all a free grower. Its hardy nature does certainly enable it to mature a slight annual growth, even in such a position, but stunted moss-clad trees are an unpleasant sight. It is, therefore, highly important that those who plant such trees should possess a thorough knowledge of the soil and situation they require.

The Wellingtonia may be taken as an instance. It is a tree that should never be planted in a permanent position without an especial preparation of the soil. What it evidently requires is a very deep, cool, and tolerably rich soil, and without this it cannot be depended upon as a lasting ornamental tree. It is, consequently, not a desirable plant for poor or shallow soils, owing to the very considerable outlay that must be incurred in preparing the stations. The many interesting accounts published during the last few years about the appearance of this forest giant in the woods of California, have created a sort of rage for it, so that there is hardly a garden to be seen that does not hold a few plants. They are generally handsome and thriving, but it is very probable that as the trees gain size, instances of failure and bad health will multiply among them, owing to the exhaustion of the too shallow soil by the strong quick growth.

It may be useful to give a few select varieties worthy of associating with the Wellingtonia in its young state. Of the Piceas, the very distinct and beautiful Pinsapo, one of the most hardy Conifers, stands first, and the elegant Nordmanniana and nobilis deserve to follow. Among Retinosporas, pisifera is very beautiful when laden with its seed; leptoclada, very symmetrical and distinct; and the dense purple ericoides, so useful for combining with the various green varieties. The Pinuses afford us the striking macrocarpa, monticola, and Cembra, all distinct and good. Then there are the Thujas, of which Lobii and aurea are the best; gigantea, or Libocedrus decurrens, is also valuable for its pleasing shade of green, but its peculiar rounded top give it a somewhat squat and clumsy appearance. Thujopsis borealis is a great beauty, very elegant and symmetrical. Of other desirable varieties I may select the Deodar, the red and white Cedars, Cupressus Lawsoniana, Abies canadensis, the Hemlock Spruce, increasing in beauty as it gains size, of which there are some noble specimens at Alton Towers, the elegant Taxodium distichum, and Araucaria imbricata. There are, of course, numerous other varieties worthy of a place, but my object is to give a few very distinct

kinds for the guidance of amateurs, to whom a long list is often puzzling and of very little service.—Edward Luckhurst.

OLD PEARS WITH NEW NAMES.

In your last number I was pleased to see an article from "T. R." on "Old Pears and New Names," and that he has been able to fix the name of the Glastonbury Pear, which I hope will be retained, if it is sent out by the trade, as I believe it is still mentioned in the French catalogues. In this neighbourhood it is first-class in every respect, both from pyramids and the wall, and where it succeeds should be extensively planted, as out of many varieties it is the best that I have grown. I have no doubt the Pear sent out the last two years by Mr. Sampson, of the Yeovil Nurseries, under the name of the Benedictine, stated to be a seedling and raised at Glastonbury, is the long-forgotten Esperione. To prove the correctness of "T. R.'s" remark, "the great change brought on some Pears by the soft mild climate of the west of England," and the necessity of trying many sorts before you plant many trees of one kind, I will state that with me Louise Bonne of Jersey, which appears to be a great favourite, is almost worthless, and does not even deserve that limited space which Mr. Rivers, in his "Miniature Fruit Garden," recommends.—I. A. P.

Esperine, of Van Mons (*Esperione*, Rivers? *Grosse Louise du Nord*, Decaisne). First to second size. First quality. Ripe November 6th, 1870, at Merriott, Somerset. Form obtuse pyriform, drawn-in near the top, much bossed, irregular in outline, and knobbed at the summit. Stalk strong, about an inch long, somewhat curved, and set a little obliquely, sometimes sunk or inserted level with the surface. Eye large and half closed, set in a wide and rather shallow basin. Skin very thin, greyish yellow, covered with small greenish dots, and spotted and netted with cinnamon-coloured russet, which becomes on the sunny side of a pale rose tint. Flesh white, rather fine, and somewhat melting. Juice very abundant, refreshing, sugary and vinous, with a nice delicate perfume.

The above description was made from fruit produced here in 1870, and the following description was made from fruit presented to me by Mr. Sampson, of Houndstone, near Yeovil, in November, 1871, and No. 2 is a sectional figure of one of the fruits.

Benedictine, Sampson (*Doctor*, of the Glastonbury gardens). First size. First quality. November. Pyriform, rather regular but somewhat one-sided, even and smooth on the surface. Skin very thin, yellow, suffused or nearly covered with bright cinnamon-coloured russet, which is brightest on the sunny side, pitted with brownish dots, and strewn with brownish specks in the shade. Stalk about 1 inch long, set in a narrow knobbed cavity by the side of a fleshy lip. Eye half closed, and set in an uneven, knobbed, and rather deep basin. Flesh white, fine, excessively melting, and somewhat gritty at the core. Juice very abundant, acidulated and aromatic, with a nice slight astringency and piquant flavour. A beautiful and delicious fruit, with somewhat of the appearance of Marie Louise, and much of the flavour and quality of that sort.

As above, I have given a true and faithful description of the fruit sent to me under the name of the Benedictine by Mr. Sampson who said that he obtained his grafts from a Mr. Lovel, of Glastonbury, and that the original tree grows in a garden, which had at some time belonged to the religious order called Benedictines. How old the tree is I have not been able to ascertain; its age would help to determine whether or not it is or could be referred to the Esperine, which was raised by Van Mons between the year 1820 and 1830, and was dedicated by him to Major Esperen. The fruit was figured by Bivort, in his "Album de Pomologie," in 1849, and later by M. Decaisne, of Paris, in his beautiful work the "Jardin Fruitier," in 1865. M. Jules Liron d'Airoles in his "Notice Pomologique," both figures and describes it. Neither M. Bivort's, M. Decaisne's, nor M. Liron d'Airoles' figures or descriptions agree with those of the Benedictine as made by me, nor do the fruit presented to me by Mr. Sampson under that name resemble the fruit of the Esperine produced here in 1870, and of which I had about half a bushel, so that I had a fair view of the sort, and I made my figure from a medium-sized one. Mr. Rivers, at page 503, thinks the Glastonbury Pear the same as the "Esperione." I suppose he means the Esperine? as I do not know a Pear called Esperione, nor can I find the name in any book or catalogue, not even in Mr. Rivers's own catalogues from 1843 to 1871, although it may be in them and has escaped my notice. I, therefore, from what Mr. Rivers has written, and from what I know of the two Pears, must withhold my decision until both sorts begin to show their leaves, a thing that will very soon decide whether the two sorts are the same or not.

As to the Brockworth Park, I have compared its wood and leaves with many sorts, but have as yet been unable to identify it, neither do I know another Pear like it in form and size, although the fruits I saw exhibited at the International Fruit Show in October were, no doubt, produced under advantageous circumstances. I doubted the Pear being a new one at the time it was sent out, and expressed myself so; yet I have not yet been able to identify it with any other. I bought it when it was offered for sale, and have multiplied it considerably; and I may state, as it takes well upon the Quince, a few years will suffice to show whether I and others have paid our guineas for something that is something else. —John Scott.

P.S.—The Brockworth Park was certainly amongst the finest if not the finest, of the specimens of Pears shown on October 4th. As most of our own pomologists and some of the best continental ones were at the Show, it is surprising that none of them recognised the Brockworth under its proper name, if it has another. The basket and splendid Pears were conspicuous enough.

[There is clearly some confusion or misapprehension in regard to the Pear referred to in the above communications and the "Esperine." On the 16th of November, 1865, we received from Mr. Porch, of Edgarley, a very handsome Pear with a communication, from which the following is an extract: —"Making inquiries from the oldest inhabitants concerning the tree, I can learn but very little. From the situation one would fancy the tree must have been a wild one, as it is growing in a hedge, north aspect, surrounded by Elms. From its great age I cannot find out whether it has been grafted." Believing it to be a new variety, we named it in our notes "Edgarley Foundling," and made the following drawing and description of it:—

Edgarley Foundling.—This handsome Pear was sent by J. A. Porch, Esq., of Edgarley, Glastonbury. The fruit is very narrow towards the stalk, which is slender and woody. The eye is bold, stout, and open. Skin entirely covered with warm, pale brown russet, which has numerous rough scales of russet on its surface; it is also speckled with grey and green dots, particularly on the shaded side. Flesh white, firm, but smooth and fine-grained, very buttery and melting, with a fine brisk, sweet, and very rich flavour, and delicate perfume. Ripe in the middle of November.

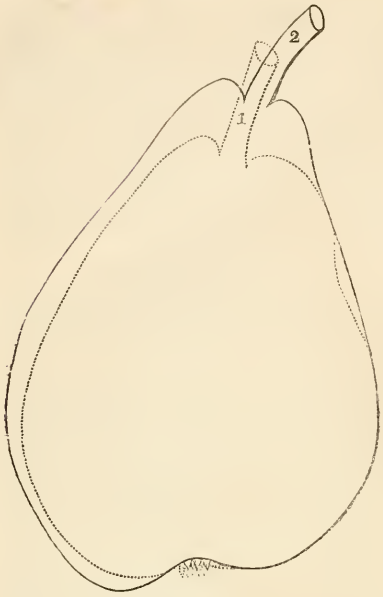
On the 18th of October, 1864, we received from Mr. Rivers, of Sawbridgeworth, a fruit of the Esperine Pear, of which the following are a drawing and description:—

Esperine.—A handsome fruit, even and regularly shaped. Skin smooth, of a beautiful golden yellow colour, with streaks and a very pale crimson cheek on the side next the sun; and round the crown, there are also some sprinklings of thin cinnamon russet here and there. Eye quite open, set in a considerable depression. Flesh coarse-grained, crisp, juicy, sweet, and half-melting, but without any merit. A second-rate Pear, ripe in the middle of October.

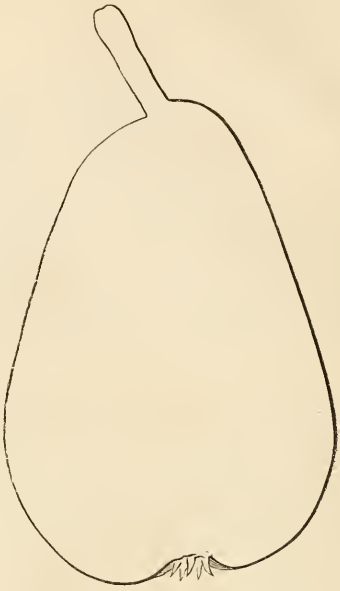
Can it be possible that these two Pears are the same? Much of the evidence for or against their identity will rest on the age of the tree at Edgarley. The Esperine Pear, which was raised by Van Mons at Louvain in 1823, does not appear to have been one of those sent by him to the Horticultural Society of London, and distributed at any period; nor is it mentioned in any of the editions of the "Catalogue" up to 1842 as being in the collection at Chiswick. It has never appeared in any nurseryman's catalogue in this country, with the exception of Mr. Rivers's, and there for the first time only in 1855 and again in 1859, and there does not appear to be any evidence of its having been distributed among us. These facts and the age of the tree are against the probability of the Edgarley Pear being identical with the Esperine.

So far we should have had no difficulty in the matter, and would have been disposed to pronounce them distinct, had we not received on the 7th of November last, from Mr. Sampson, of Yeovil, a fruit of Benedictine Pear, which is said to be identical with the Edgarley, but which appears to us to be distinct from what we have seen of that variety. The figure and description we made at the time, are as follows:—

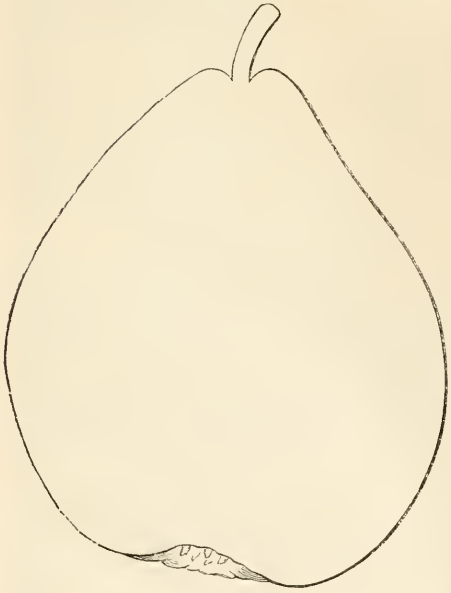
Benedictine. — This handsome Pear very much resembles Brown Beurré in form and colour. The eye is open, the stalk short and stout, and the flesh is very juicy, but also very



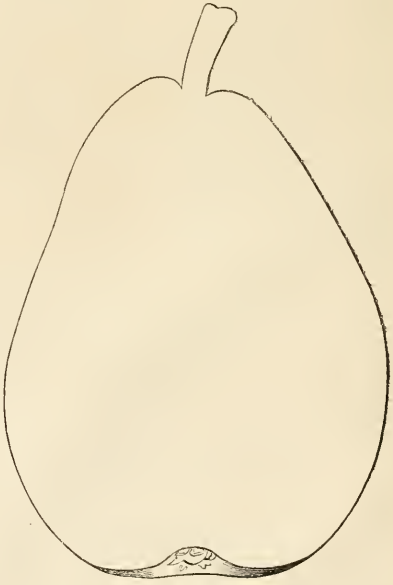
1, Esperine. 2, Benedictine.



Esperine.



Edgarley Foundling.



Benedictine

gritty, with a brisk, acidulous, refreshing flavour, without richness or aroma.

Our own opinion is that the Edgarley Pear and Esperine are quite distinct; and as regards the Benedictine, it is quite possible that the fruit we received may not have been a characteristic specimen, and the inferior quality may have been due to the season. There can be no doubt whatever that the Edgarley Pear is a very excellent one.—Eds.]

MUSA ROSACEA.

This species is a native of the Mauritius, and is very ornamental in the stove, but I am not aware that it has been tried in the open air during the summer months, nor do I think the result would be satisfactory if it were so used. M. rosacea, like the beautiful M. coccinea, does not belong to that section of this genus which is prized for its fruit-bearing qualities. Its estimable features are a noble port, handsome flowers, and a growth from 10 to 15 feet in height. These plants are stemless, although they are generally described by the majority of people as having stout and tall stems, which in reality are composed of the very long and compact sheathing bases of the leaves. The blade of the leaf in the species here figured is dark green and oblong, with a prominent midrib. The bracts of the flowers—the special objects of attraction in this plant, are a beautiful, long-lasting, rosy pink, and, combined with the noble appearance of its leaves, produce a splendid effect in any group of plants with which it may be arranged. I would strongly urge upon every grower of stove plants who does not already possess this Musa, to add it at once to his collection, if sufficient height can be allowed for its accommodation.

Musa rosacea.

The cultivation of these plants is extremely simple. When young pot them in about equal parts of good rich loam, well-decomposed manure, and leaf mould, with a little sharp river or silver sand added. After they have attained to some size a little less manure should be given, for as fruit is not expected of them, the withholding of a little nutriment will only induce them to flower earlier. They enjoy copious waterings, and in the case of the fruiting varieties liquid manure is extremely beneficial, though I have never used it for this species.

In a young state M. rosacea forms a beautiful object for the decoration of apartments, and even when it grows too large for vases in the drawing-room, it may be used with advantage for halls or staircases, or when any special decorations for grand parties are required. I am not aware that the species here figured is used economically in any way, but several of this genus are extremely useful. One in particular, M. textilis, yields what is known as the Manilla Hemp, and is largely cultivated in the Philippine and other islands for its fibre. The finest portion of this is used for shawls, and I am informed that a great quantity of the chignons which adorn (?) the heads of the fair sex are also derived from this source, the coarser material being used for ships' ropes, &c.—Experto Crede.

STRAWBERRY CULTURE.

You have had several papers on the cultivation of Strawberries, and about these I think there is still much to be learnt, especially with regard to the soils and localities suitable to the different sorts.

Some years since the variety Dr. Hogg was so much praised for quality and hardiness that I discarded British Queen in its favour, and have been grievously disappointed. Last season, having planted it freely, I expected to gather a full crop, and a more ragged, miserable result surely never vexed the heart of a sanguine cultivator. From a row of nearly 70 yards in length I do not think I gathered a quart of Strawberries, and the plants are poor starved specimens which merely exist. I thought this might be owing to the soil being too light and calcareous, but the crop and the plants are no better where the soil is more loamy and free from lime. La Constante is very little better; the plants seem more hardy, but the crop is very indifferent.

I think if some intelligent cultivators were to publish in

your Journal their experiences the information would be of great value, specifying at the same time the character of the soil as regards the clay, the lime, and the iron, the sorts that grow best, and those they cannot grow satisfactorily. In this way the ordinary grower would eventually obtain some guide which would save him much time and many disappointments.

The soil in my garden varies from a light alluvial to a stiff clay; in the former I have found Rivers's Eliza, Eclipse, Keens' Seedling, Sir Joseph Paxton, and Duc de Malakoff succeed well. In the heavier soil the Roseberry, British Queen, Yates's Seedling, and the Vicomtesse Héricart de Thury do tolerably well.

Many years ago, in consequence of some information (but whence derived I have forgotten), I dressed a worn-out Strawberry bed with the refuse of a brick-kiln, and the burnt earth and fragments of bricks were put on rather thickly between the rows. The effect was very good, and the blooms and fruit exceedingly fine. Recollect that this was a worn-out bed. Not having access now to the same material, I have not repeated the experiment.—T. G.

MADAME CHIRARD AND OTHER ROSES.

I RECEIVED the following from Mr. W. Paul:—"In my judgment you are right in recommending Madame Chirard. With me it is quite first-class; and everyone who sees it pronounces it so. I first met with it in the nursery of Pernet at Lyons, the same year that I saw Baronne de Rothschild in the same nursery, and I find that I marked them both as 'first-rate.' As I journeyed northwards I found at Orleans Madame Alice Dureau; and this I also marked first-rate [It is so here—W. F. R.], with the additional note that I rather preferred Madame Chirard." I do not think it equal to Perfection de Lyon or Madame Chirard, two grand Roses, of excellent growth and general good attributes; but it is still a first-class Rose in the line of Reine du Midi, which does not bloom freely here. Reine du Midi is spherical and fine when it opens freely.

There is no Rose in the line of rose-colour equal to Louise Peyronny *alias* Lælia, but it is not very strong in constitution, although derived from La Reine.

I thank Mr. Peach and the electors much. Their selections of Roses are good on the whole; but, as far as my experience goes, in this exposed place, I make out two reluctant bloomers, six *presque pleine*, and six bad growers on the Manetti stock. Roses which are *presque-pleine* Roses are valuable for the garden, as they bloom freely in bad weather, and bloom late in the season, but they are bad for travelling, and show early in summer "a shilling eye."—W. F. RADCLYFFE.

THE ROYAL ASCOT VINE.

REFERRING to the Journal of September 22nd, 1870, page 221, respecting this Grape, I am very happy to say I am now in a position to speak most highly in its favour. As a Vine for pots it is quite first-rate, being very refreshing to eat, and so black as to look well against the green leaf when used for table decoration, while for Grapes to cut in winter and early spring it stands without an equal. If strong selected fruit-eyes are started in January, and the green canes stopped in July, a nice crop can be obtained in the beginning of the next year and onwards from plants in 15-inch pots. Thus in about twelve months from starting the eyes you have the reward of all the labour and care. A small dung bed and a glass house without much fire heat are what is required. With a little tact, from 15-inch pots capital ripe Grapes could be obtained in July and January out of the same glass building.

When the Vines have fruited once I throw them away. I know that by such treatment it will do well, but as to its bearing perpetually I will say nothing. Trying to make a Vine, or indeed any plant, work on with little or no rest is an attempt to upset the laws of Nature, and from which I rather abstain. I advise those who have it not to obtain it. With me it is grafted for growing in ground vineries, but I intend another season to try it also against a wall, when I will state the results, and the stocks I have used. Its hardihood and free bearing are unexceptionable. I send with this communication (December 26th), a bunch of miniature Grapes obtained from a green cane of this year's growth in a 10-inch pot, which stood against an eastern wall on which the sun ceased to shine at 11.30. Here several bunches were produced. When the nights became frosty, however, it was removed to an outhouse until I had time to write this. I removed it in order to see if in so low a temperature bunches could be obtained from green canes of the same year's growing. Had the Vine been removed to a glass house, slightly heated, all the bunches would have ripened.

The failure I mentioned was totally owing to the Vines which I received being from an exhausted stock, brought about in the eagerness to produce a quantity of Vines in a very short time. The Golden Champion, I regret to see, is much written against. I have seen some grand bunches in Yorkshire grafted on Bowood Muscat, but I think a more hardy stock would suit me better. I shall try my best with several stocks, because so noble a fruit is worthy of some painstaking.—R. M. W., *Fir View, Walkley, near Sheffield.*

LILIES.

I HAVE never found any difficulty in growing Lilium japonicum, which thrives with me in peat and leaf mould. I winter the pots of this and other Lilies, plunged, like Hyacinths and such things, in sawdust, anywhere out of reach of actual frost. I think the first, or slow-growing period, should be prolonged as much as possible, after which the warmer berth of greenhouse or conservatory encourages development to a high degree. A free circulation of air is, however, indispensable, and the contrary most prejudicial—to wit, anything of continued close and moist treatment.

Much as I object to peat for general cultivation, Lilies undoubtedly like it. They will, however, do well and healthily in loam, with leaf mould or very old hotbed manure. This is all that is necessary for the Martagons and other hardy sorts, still I find myself giving a "bit of peat" to a favourite. L. longiflorum will flourish planted under a wall for years, and I have had beds of it in great beauty under peat treatment in a genial situation. It is apt, as my friend Mr. Wilson says, to suffer from early frosts. In this case gangrenous spots appear on the leaves, and the plants are checked and injured. Even the common white Lily sometimes suffers in the same way here. L. japonicum sometimes lies dormant for a year, which I believe is induced by too dry a season of rest. L. Wallichii I never could induce to start at all. L. tenuifolium came up freely from seed, and thrived in absolutely pure sandy loam under a glass frame in front of my stove. L. testaceum luxuriates with me out of doors in strong loam heavily manured.

Lilies seldom grow or flower strongly the first season out of doors after transplanting. They sometimes, too, resent division in-doors. When a mass is broken-up for stock, rather small pots should be used, and the plants brought on slowly. I should be glad to know what Lilies are known to produce seed in England. I have only observed it upon the old Martagons, chalcedonicum, the old orange, and once upon L. testaceum, out of doors; in-doors, L. tigrinum speciosum and giganteum have seeded, but L. japonicum and longiflorum never.

Your correspondent's autumn Daffodil might be Oporanthus luteus, obtainable from the nurserymen, perhaps even now.

By the way, Lilium longiflorum, which forces very fairly, becomes after that operation almost a perpetual, jumping up and flowering at all sorts of odd times, sometimes "*In tempore quod rerum omnium est primum*"—say just in time for your Christmas ball. Candidum forces well.—R. T. CLARKE.

HOW TO DIVIDE A PIT ECONOMICALLY.

"A" HAS a pit 60 feet long, with hot-water pipes along the front and across one end. Now, could he manage to keep out the frost, he would make a hotbed at that end, but at present the heat, by diffusing itself, prevents his doing so. He would also like to use the bottom of the pit for standing pots from 12 to 15 inches in height upon, but he is told that this would necessitate the formation of brick divisions, which would seriously interfere with the existing arrangement of his water pipes, and entail an expense he does not wish to incur.

The advantage of having the floor of the house divided is that one can so regulate the temperature in the one, two, or three lights forming a division, as to grow plants requiring the most different temperatures in each, keeping that compartment in which the pipes meet at right angles, for those that need the highest. Now to effect a very temporary division a clean, double mat would do well, a strong piece of calico on a frame better, and a partition made of three cross pieces and half-inch boards best of all. The bottom should run from wall to wall at any depth required, and the top should be made to suit the slope of the rafter, leaning lightly against it secured by a nail

or screw, so that the sash could slide freely. We find these constructions very useful in a number of cases of which the following may be taken as an instance:—Four lights of a pit have been filled with cuttings, some are half-struck, others want a fortnight of attaining that condition. Place the struck ones in two lights, and the unstruck in the other two; insert the wooden partition between them, and then you will be able to give warmth and closeness to the one division, and air, so as to harden-off, to the other.—R. F.

OUR EDIBLE FUNGI.

That any of our indigenous Fungi, other than the familiar and fragrant "pink gill" of the pastures (Agaricus campestris), are wholesome or fit to be eaten is a thing which finds small credence even among those who might be supposed to know better. Now, nothing can be more contrary to fact than this mistaken idea, and it is desirable that it should be generally exploded. There are many other species, almost, if not equally, valuable, which, through ignorance, prejudice, or both, are allowed year after year to spring up and grow and waste, when a little knowledge would cause them to be sought after, and converted into useful and delicious articles of food.

Let us take a case in point which the present year affords, as showing that no small advantage would be derived from even a very slight acquaintance with the more familiar forms of our edible Fungi. While the ordinary field Mushroom was this year almost a blank, and the supply for the manufacture of catsup all but *nil*, the Champignon, Marasmius oreades, a species equally palatable, and capable of producing a far superior catsup, was allowed to wither and to waste unheeded, though it might have been largely and profitably availed of for the production of this last-named article of *cuisine*.

Another case, for which, however, we must go back to last year—by the way, a real Mushroom year. In journeying up and down the Great Southern line we, as well as many others, in passing through some of the rich feeding grounds of Kildare, were struck with the marvellous patches of Mushrooms of all sizes, from that of a cheese-plate to a platter. Our astonishment was rather increased on the return journey to see these beautiful-looking "flaps" remaining ungathered. We at once concluded that the abundant supply was in excess of the demand, and that they were not considered worth the gathering. However, on since thinking over the matter, we incline to believe that they belonged to the nearly allied and equally useful and palatable Agaricus arvensis, or Horse Mushroom, and that prejudice, not the consideration of profit, was the cause of their being left to bleach and wither.

Some years ago we took occasion in this Journal to allude with regret to the want in our public institutions of well executed models of at least the commoner forms of esculent Fungi, as also of their deleterious compeers. At Glasnevin Botanic Garden, where it could be seen by such numbers of the public, and specially accessible to gardeners, young and old, such a collection would be of the highest value, in improving their acquaintance with, and enabling them readily to identify at least the most useful kinds.

However, no models, no matter how beautifully and accurately executed, can be so instructive as recently collected specimens; and our reason for alluding to the subject to-day is, that we may inform our readers that in the course of the coming year there is a probability of such collections being for the first time placed before the Dublin public. The learned Professor of Botany in Trinity College, Dr. E. Perceval Wright, being anxious to familiarise gardeners and the public with their forms, and remove some of the prejudice which exists against their use, liberally proposes to offer prizes for the best collection of edible Fungi, correctly named and tastefully set up, to be competed for at the Special Fruit Show of the Royal Horticultural Society of Ireland, to be held in the second week in October next. In order further to provoke spirited competition and an interesting display, the Society will supplement Dr. Wright's prizes with its silver gilt medal for the first prize, its silver medal for the second, and bronze medal for the third. We trust that not only will the call be responded to by our scientific and gardening friends at home, but that some of the many accomplished gastronomic fungologists of England may be induced to come over with instructive collections.—(*Irish Farmers' Gazette.*)

Training on Walls.—As cottagers often find a difficulty in training trees upon a stone or other rough wall, a very good plan is to nail osiers or hazel 7 or more inches apart on the wall, and train the trees upon them by tying-in the branches. This will save nails, as a rod 8 feet will require but a shred at each end and one in the centre.—Cangort Park.

BURGHLEY HOUSE,

The Residence of the Marquis of Exeter.

In "Domesday Book" it is spelt Burghelei and Burglea, and detailed as part of the endowments of Burgh Abbey. In later archives it is described as "the manor of Burle, in the township of Burle, near Pillesgate."

Racy and interesting are the memoirs of many of its earlier tenants, but we must pass them over to note that it came into the possession of the Cecils on the suppression of Burgh Abbey, in the reign of Henry VIII.

The chief portion of the mansion was erected by the celebrated Lord Treasurer Burghley during the reign of Elizabeth, and the dates on various of its parts range from 1577 to 1587. A residence had been erected on the same site by some of his ancestors, for he says in one of his letters, "I have set my walls on the old foundation. Indeed, I have made the rough stone walls to be square, and yet one side remaineth as my father left it me."

The Lord Treasurer was the first to form a park around the mansion, but it was much enlarged by the Earl of Exeter in 1665, and though we cannot precisely state its acreage, we believe its circumference is about eleven miles. In a portion of this park, as there probably is underlying the whole of it, iron ore has been found near the surface, and this is now being worked.

Burghley is no exception to the rule, No ancestral hall is without its romance. Burghley, in truth, hath its many romances, but we will only particularise, and that very briefly, one versified by Tennyson.

Henry, first Marquis of Exeter, retaining only his family name, retired to Bolas in Shropshire. He there wooed and won Sarah Hoggins.

> "He is but a landscape painter,
> And a village maiden she."

He represented that he was poor—

> "I can make no marriage present,
> Little can I give my wife;
> Love will make our cottage pleasant,
> And I love thee more than life."

Towards that "cottage" they journeyed; seeing

> "whatever's fair and splendid
> Lay betwixt his home and hers."

At length they reached

> "a mansion more majestic
> Than all those she saw before."

She wondered to see the deference with which he was received, and the freedom with which he passed "on from hall to hall," but the solution was at hand;—

> "For, while now she wonders blindly,
> Nor the meaning can divine,
> Proudly turns he round and kindly,
> 'All of this is mine and thine.'"

She was "The Lady of Burleigh," and gladdened should we be if we could add that she sustained long and firmly her elevation, but the transition was too sudden; her spirit was not self-reliant—she feared that she could not worthily be the Marchioness—

> "So she droop'd and droop'd before him,
> Fading slowly from his side;
> Three fair children first she bore him,
> Then before her time she died."

Burghley House is about a mile to the east of the Stamford station of the Stamford and Essendine Railway—a railway made by the Marquis of Exeter; hence it has been said that travellers by it are the Marquis of Exeter's passengers. It need hardly be remarked that when our great trunk lines were projected great opposition was made to them by the gentlemen through whose estates it was proposed they should pass, and originally it was intended to take the main line of the Great Northern through Stamford on the old Great North Road, but the Marquis of Exeter of those days opposed its passage, and successfully. Stamford, great in coaching days, suffered much from the diversion of the traffic by road without receiving compensation in the shape of railway communication with the great towns of the kingdom; but now all that is changed. By the little line just referred to it is brought into connection with

the Great Northern system, and the North-Western and the Midland lines each have branches to Stamford, so that perhaps no town of equal, if not greater, population is so well provided with railway accommodation. It is not improbable that the opposition to this in the first instance was the best thing that could have happened, for, the want being felt, the railway companies were all the more anxious to meet it.

The principal entrance to the park is on the Great North Road, but there are others in different directions leading through avenues variously planted with Limes, Elms, and Chestnuts. The mansion faces a little to the west of south, consequently the other side has a north-easterly aspect; it is on the latter side that the carriage circle is situated, but it strikes one that something is wanted to break the flat appearance of the wide circle of turf enclosed by the broad gravel drive, say a statue or a fountain, which must, however, be of a character to accord with the building—not necessarily gorgeous, like the richly-gilt wrought iron gates which give access to the house on this and the west side—but noble in its appearance. Round the outside of the circle is a narrow border which in summer is occupied with Dahlias, Hollyhocks, and other flowering plants interspersed among the dwarf shrubs which are the permanent occupants. On the west side the most notable object is a small-leaved Lime tree planted by Queen Elizabeth, and therefore more than 300 years old; its trunk is about 7 feet in diameter, but though preserved with all the care due to so ancient and venerable a tree, its years are numbered, for its limbs, though chained together and propped up, creak ominously, and must eventually give way before one of those strong "sou'-westers" to which it is so much exposed. But there is life in the old tree yet, and when such a catastrophe shall have occurred the stump, which will probably be left, will doubtless throw out fresh branches, and though then for many years the tree will be little better than

Burghley House.—South-west View.

a pollard, it will still remain as a memorial of the Virgin Queen and her far-seeing minister. On the south, or more strictly south-west front, of which we give a view, are a thriving young Oak—at least, young as Oaks grow—planted by Her Majesty when on a visit to Burghley in 1844, and a Lime tree planted by the Prince Consort. Extensive views over the lake and park are obtained in this direction, in one of which a bridge of three arches is seen spanning the water. Eight handsome standard Portugal Laurels in tubs are placed along the terrace walk and sloping lawn in front of the mansion. On the east side is what is called the Orange Court, in which are several stone-edged oval beds grouped round rockwork, in the centre of which is a fountain with an oval basin about 16 yards long by 12 in its shorter diameter. The basin was empty, having been cleared out to be stocked with fish artificially hatched. The orangery, like a great many others in this country, has been turned to other purposes than plant-preserving, though it contains a few Camellias.

Burghley has no conservatory, and the only plant houses are three substantially-built lean-to's, with stone shelves in front and stages at the back. These are chiefly occupied with old plants and cuttings of Geraniums, by Azaleas, Cinerarias, and plants for house and table decoration, such as Draccenas, Coleuses, Ferns, and a number of excellently-bloomed Chinese Primulas, of which Mr. Russell, who manages this part of the garden, finds the double-white very useful for bouquets, as the petals do not drop so readily as those of the larger-flowered and more showy single kinds.

The pleasure grounds surrounding the house cover between thirty and forty acres, including a large extent of kept grass, which of course involves a heavy amount of labour, and owing to their situation being a breezy upland, it must be difficult to keep the lawns so free of leaves as they were when we saw them. There is an American garden occupying a large circle under the lee of a mount, likewise a rosery; and near the shores of the lake is a garden of 145 small geometrical Box-edged beds, which must be very difficult to plant, as the beds form complete designs from various points of view, and still more difficult to keep in order from their small size, many angles, and exposed position. At the head of the lake there is also a series of long beds on one side of the walk along a bank probably artificially formed, and on the other the ground rapidly descends, and is densely clothed with Laurels and other shrubs. Laurels both Common and Portugal, but especially the former, are planted in great numbers by the sides of the pleasure-ground walks, as they thrive so well under the trees. Of these there are many noble specimens of the Cedar of Lebanon, one having a stem nearly 5 feet in diameter at the base; there are several others almost as large, but not so handsome, having lost some limbs through wind and snow. There are good trees of the Hemlock Spruce and some other Pinuses, but the number of those not indigenous to this

country is not large, nor is the soil favourable to them. The overflow of the lake forms a waterfall, descending into an old quarry now planted, and bears such a resemblance to that at Bowood, though it is on a smaller scale, that one is led to suspect it is the work of the same hand, especially as the lake of thirty-two acres has probably been formed in a similar manner to the one at the place referred to. One of the most beautiful views of the lake is seen in the accompanying engraving from a clever photograph, but since it was taken the boat-house has been pulled down and a new one has been commenced.

In a gardening point of view, however, the great feature of Burghley is its kitchen garden, of which the ruling genius is Mr. R. Gilbert, whose name is well known as a successful exhibitor of fruit and vegetables, and that not in local competitions, but in such as have taken place at Kensington and Nottingham. The garden in which these products are grown, situated far to the south of the mansion, from which it is separated by a wide breadth of the park, is one of the largest in the country, covering about fourteen acres within the walls, but there is also a large area in outside slips, besides an orchard of four acres, in which are grown Sea-kale, Rhubarb, and Greens of various kinds, as well as fruit trees.

We will first enter the houses, which are models of neatness and cleanliness, the walls fresh limewashed, the woodwork not long painted, the glass perfectly clear, and not an insect to be seen. The first vinery is a lean-to, 60 feet by 15, and the Vines are chiefly, if not exclusively, Black Hamburghs, which have been planted about forty years; but by grafting Mr. Gilbert is introducing Black Damascus, Ferdinand de Lesseps, and several new kinds. The scions worked on the old Vines are taking remarkably well, and are treated on what may be termed the bottle system, the lower end being inserted in a bottle of water. Between this house and the second vinery is

The Lake at Burghley

a lobby filled with Chinese Primulas, Callas, Mignonette, and various other decorative plants, among which is the Borage, ornamental by its blue flowers, and useful for claret cups as well. Vinery No. 2 at present contains the Mill Hill Hamburgh, but Mr. Gilbert purposes planting it with Lady Downe's and other late kinds, making the border inside. It also contains a number of Pine suckers, Vicomtesse Héricart de Thury, and other Strawberries on the top shelf, both small and large Vines in pots for the dinner table, Peas, and Potatoes. The next two houses are each 30 feet by 15, and are occupied with pot Vines, chiefly Black Hamburghs and Sweetwaters, breaking very regularly, and Pines to be started at the beginning of February for fruiting. To prevent bleeding in the Vines a kind of varnish is employed, which sets hard and appears to answer the purpose effectually. Two Muscat houses come next, in which fine crops have been produced; indeed an excellent crop still remains, though one-half has been cut. Trebbiano, which Mr. Gilbert esteems highly as a large late-keeping Grape, is to be introduced into these houses, as well as other kinds, which will carry the supply further on in the spring. Vineries Nos. 5 and 6 are devoted to Lady Downe's, West's St. Peter's, Mrs. Pince, Trebbiano, and Alicante, of which the crops are excellent. A span-roofed house in two divisions comes next. This is efficiently heated by three rows of 3-inch pipes, with evaporating tanks, on each side, and three 4-inch pipes for bottom heat under the bed, which is 7 feet wide. One compartment is devoted to Cucumbers, which are trained on a trellis under the roof, and are bearing freely; the other is occupied with Dwarf Kidney Beans, of which a large supply is required.

The next two houses are half-spans, each 40 feet long, and are filled with one of the healthiest stocks of Pine Apples which it has ever been our lot to see. The varieties chiefly grown are Thoresby Queen, Black Jamaica, and Smooth-leaved Cayenne. These, which are intended for July fruiting, are all planted out in a 9-feet bed of loam and bone-dust. The latter Mr. Gilbert finds an excellent healthy stimulant.

Two more lean-to houses (10 and 11), are the first and second Peach houses. The trees in both are in admirable health, and trained with the greatest care to curved trellises 3 feet from the glass. The varieties are Royal George and Noblesse; the former was in blossom in the early house. Figs occupy the back walls, and Strawberries the shelves at top. Another Peach house has recently been planted with Early York, Early Beatrice, and Victoria Nectarine, and is intended in future years to form the earliest Peach house. There is in addition a small Fig house, besides the hip-roofed fruiting Pine pit, which is amply supplied with both top and bottom heat, and contains a large and remarkably healthy stock of plants, with excellent fruit in various stages. At the warm end there is a plant of Musa Cavendishii, which is now bearing a cluster of fruit, but to what size it will ultimately swell it is,

of course, impossible to conjecture. Some idea of the number of Pines grown may be formed from the fact that Mr. Gilbert is supposed to have a Pine ready for table whenever one is required.

We will not enter largely into the vegetable-forcing department, though heavy supplies are required and produced, and that, too, of excellent quality. For instance, of Asparagus there are eleven lights, affording gatherings from November until it is obtained from the open ground, whilst of Mushrooms the production, in abundance and excellence, is remarkable; indeed Mushrooms are quite a speciality with Mr. Gilbert, and he obtains them at all seasons with certainty and ease in a well-constructed house with beds on arches, under which Rhubarb and Sea-kale are forced, and Endive brought on and blanched. The mode of cultivation which Mr. Gilbert pursues was thus described by himself in one of our former volumes:—

"I procure two cartloads of good fresh stable manure, and shake out the longest of the straw. I am not, however, very particular about this. Then it is turned over in the open air once or twice to get rid of the rank steam. When this is gone the dung is taken into one of the sheds at the back of the houses, and about four barrowfuls of ordinary fresh soil mixed with it. The bed is then made up on the floor of the shed to a depth of about 12 inches, pressed rather firmly, and spawned when at a temperature of between 75° and 80°. A covering of about 1 inch of good strong loam in a rather rough state is then added, and beaten level with the spade. By using heavy loam as a covering, the Mushrooms produced are of a much more solid character than where light sifted soil is used; they are, consequently, more valuable, commanding a far higher price in the market. The whole is then covered up with at least 9 inches of straw or long litter.

"I never use any fire heat, as I consider that a piece of useless extravagance. Better Mushrooms can be grown without fire heat than with it, and a continuous supply kept up throughout the coldest winters. Then, if it is so, why should our employers be put to so much expense in erecting and heating grand dungeons for this dainty, which can be so easily cultivated without their aid?"

Three ridge beds out of doors have just been spawned, and three more are shortly to be made, so that there is every prospect of the ample supply of Mushrooms being continued throughout this as it has been in past years. In one of the outside slips is a very cheaply formed and useful pit for Carrots, Radishes, and new Potatoes. Instead of glazed sashes the glass slides upwards and downwards in grooves, in the same way as in some very economical protectors which Mr. Gilbert has had made as a substitute for hand-glasses. The latter are of the best inch deal, thrice coated with paint, and, glass and labour included, cost but 3*s.* 6*d.* each. There can be no doubt that as protectors they will prove more effective than hand-glasses, more durable, and cheaper in the long run as well as in their first cost. With regard to the houses, it should be added that there are but three boilers, the whole of the vineries and peacheries being heated by one of Weeks's tubular boilers, with a spare one in case of accident, and some of the smaller house by a saddle boiler.

In the kitchen garden compartments, of which there are six, enclosed by 12-feet walls, with 16-feet borders, are all the usual crops in excellent condition, and nothing could be better than the condition of the trees on the walls—Pears, Peaches, Nectarines, Apricots, and Figs. The first-named are horizontally trained, in stages about 18 inches apart, and consist of a selection of the best kinds, ripening in succession; and among the Peaches are several twenty-three years old, lifted and replanted last year, and looking none the worse of the operation. In one of the borders Potatoes were being planted for early use, the kinds being Coldstream Early, and Paterson's Victoria, which Mr. Gilbert prefers to kidney varieties; in another border is an excellent stock of Snow's Winter White Broccoli, sown at the end of March, to succeed Walcheren, just over; and in a third a very fine stock of Brussels Sprouts, ranging from 3 feet high, with the stems densely set with fine large sprouts. These were the result of three seasons' selection, but Mr. Gilbert thinks a further selection necessary to render the strain permanent. Extensive quarters of Gooseberries, well-managed pyramid Pears, and all the ordinary kitchen-garden crops are excellently represented. We have now only to add that the fruit-room, root-stores, and the other requisite structures are conveniently and well arranged; that in the young men's rooms the convenience and comfort of the inmates have been duly attended to; and lastly, that the order, neatness, and ability with which everything is managed, reflect the greatest credit on Mr. Gilbert, whom we have long known as one of the best gardeners in this country.

HEATING BY HOT WATER.

Notwithstanding all the elaborate essays that have from time to time appeared in the horticultural press on heating hothouses with hot water—not to say anything of the stirring controversies that have taken place on the subject—we have the best reasons for believing that many whom the matter intimately concerns have still but very vague and erroneous ideas regarding the principles upon which the proper adjustment of hot-water boilers and pipes depends. And from some cause or other, it is a notion very prevalent that the easiest and shortest way to get deeply immersed in the disagreeable and undefined difficulty figuratively termed "hot-water," is to plunge into this heating question, in which are involved furnaces, boilers, pipes, fire, and water, besides that unfortunate being who has to control the elements and conditions of combustion so as to have half-a-dozen thermometer-needles in as many hothouses standing at certain hair-like marks at half-a-dozen different times in the four-and-twenty hours.

It is our belief that, if those who have to do with fixing pipes and boilers were to make themselves acquainted with the effects of heat and the power of gravitation on water, it would be next to impossible to commit the blunders, and resort to the unnecessary and expensive precautionary measures, one so often meets with and has to deal with. It is no part of our intention to pretend to deal with that imponderable and powerful agent called by men of science caloric, but which we shall call heat—hypothetically regarded as a subtle fluid, the particles of which are to each other repellent, but attractive to all substances, though in various degrees. But the effect of heat upon water, an element composed of minute and distinct particles that are supposed not to have the quality or power of transmitting heat the one to the other, as in the case of solid bodies, is one of the matters concerning which some knowledge is indispensable in the case of all who have anything to do with heating by means of heated water circulating in pipes.

The particles of which water consists, it need scarcely be said, have a capacity for heat from different sources, but most manifestly so to us in this case from combustion on the fire. Now the expansion of bodies is one of the most universal effects of increasing their heat. This expansion takes place to a greater degree in some bodies than in others. Liquids expand much more by the same increase of heat than solid bodies, and air more than either. With the expansion of the individual particles of water, their specific gravity becomes less; in other words, they become lighter in proportion to their size. Here lies the whole secret of hot-water circulation in pipes and boilers, and the well-known law which should regulate their relative positions the one to the other. The heated particles of water bound upwards, and, as "Nature abhors a vacuum," their place is taken up by a rush of colder and heavier particles. It is of very little practical use to cavil about the question as to whether heat or the greater specific gravity of the cold water which jostles up the warmer and lighter plays the greatest part in sending up and away the stream of hot water. Both have a hand in it, no doubt. This influence of heat upon water can be very manifestly shown by filling a tumbler with cold water, and mixing with it some coloured particles of matter, and then immersing the tumbler in a vessel filled with hot water. It will at once be seen, by the motion of the particles of coloured matter, that at the sides of the tumbler there is an upward current of heated, and in the centre a downward current of colder, water. And this goes on until the whole is of the same temperature. A glass of warm water immersed in cold has the current reversed in its course—upwards in the centre, and downwards at the sides, where the water is being cooled. Here we have the whole secret of the motion and course of heated water in the boiler and pipes of a properly-adjusted heating-apparatus. And one would suppose that the simple understanding of this would prevent any from making mistakes. Yet, strange to say, many who undertake hothouse-building are entirely ignorant of these simple and well-established facts.

Wherever the heat generated by combustion in the furnace acts most directly and powerfully, from that surface bound upwards the particles of water, and to that spot, simultane-

ously, drop the colder particles of water, to be in their turn sent bounding on their errand of warmth; and anything that attempts to contravene this law of gravitation will be rebelled against by the elements concerned with unmistakeable violence and persistency. Clearly, then, the outlet for the water, thus lightened and charged with its freight of heat, should be at the highest part of the boiler; and that by which the cold water is to run in and down, to take its place, should be at the lowest point. Boiler-inventors and manufacturers recognise this important part of the matter, and always place the flow-pipe at the highest, and the return-pipe at the lowest, point of boilers.

Great importance has been attached by many to the necessity, or at least the great desirability, of having the boiler fixed at a very much lower level than the pipes; and also to the necessity of laying all the flow-pipes on the incline the whole length of the house to be heated. The importance, too, of having the return-pipes on a considerable decline, has, in our opinion, been very much over-estimated. It is entirely unnecessary to form deep, damp stokeholes, in order to sink the boiler to a level below the main body of the pipes, as is so very frequently met with. And as to having the pipes running at an incline after starting from so high a level, we consider it entirely unnecessary. Indeed, one of the most efficient heating-apparatus we ever superintended, started from about a foot above the level of the boiler, and ran down a gradual decline into the boiler. Immediately the water enters a hothouse it begins to part with the heat absorbed from the fire, gets colder, increases in specific gravity as it speeds in its way back to the boiler again, and a downhill career is most natural to it as soon as it leaves the highest point of action, where its heat is the greatest. Practically, we have never found much difference when the pipes went the whole length of the house on an incline, or on a dead level all the way round till it came near the boiler and dropped into the return-opening of the boiler. Indeed there is little fear of a good circulation, provided the pipes do not at any point descend and rise suddenly, and most especially that at any point they do not dip below the level of the return-opening into the boiler. We have had the working of apparatus where pipes, descending perpendicularly, crossed under a walk and rose again perpendicularly to heat another range of 80 feet of glass; but at none of the points were the pipes within a couple of feet of the level of the return-opening into the boiler. This undesirable arrangement worked pretty well until hard firing became necessary, when the result was that the water was thrown out in plunges at the supply-cistern. Such an arrangement should always be avoided; for if it start from the warmest part, it must be forced work for the hottest water to go downhill, and it is equally so to send it uphill cold.

There is another error frequently committed in arranging the route of the water. Suppose, for instance, a boiler fixed at one end of a house of say 80 or 100 feet long, as part of the work allotted to it. As in the case of span-roofed houses, it may be desirable to have three or four rows of pipes all round the house. Now it is not uncommon to find two rows called the flow-pipes taken all round the house to near the boiler, and there to start back with other two on the same route into the return-opening of the boiler. This is giving the water a long journey, and the return-pipes will be found comparatively cold by the time the water gets back by the same route to the boiler. Now, if instead of this the whole four pipes be connected with the flow-pipe, and go round the front and end of the house on a level, and start along the back on a decline to the boiler, and there plunge down the drop-pipe into the return-opening of the boiler, it will be found that while any portion of the pipes may not be quite so hot as at the beginning of the two flow-pipes in the former case, there will not be any portion of them nearly so cold as the last portion of the return. We do not say that this is the best way to conduct the water; but we have proved from experience that the arrangement indicated is the better of the two named, when the pipes are, from any necessary conditions, laid all round the house in this way.

The supply of waste water to the boiler and pipes is often placed anywhere that looks most convenient; but the proper place is to attach the supply to the return-pipe somewhere near the boiler. Fixed to the flow, it will be frequently plunged out by the upward tendency of the hottest water. It is also very undesirable to leave the supply cistern to be kept full either by pouring in water from a pot or by turning a tap, which is often neglected. There should always be a cistern supplied by the action of a ball-cock, and then the anxiety connected with the neglect of supply does not exist.

A great many methods of supplying moisture to the atmosphere of hothouses in connection with the heating apparatus have been adopted—such as zinc troughs placed on the pipes, troughs cast on the pipes themselves, a flow of water running in an open gutter, rising out of the flow at one end and dropping into the return at the other. We have tried all these, and more besides. The best we have tried is, first, to fix a flat-bottom open trough, 2½ inches deep, and 6 inches wide, the whole length of the pipes in front of the house; this trough to have no connection with the hot-water pipes beyond resting on them at a level. In the centre of this trough is fixed a 2¼-inch-in-diameter rain-water pipe, jointed with Portland cement—the best of all joint-cement. This rain-water pipe is connected with the flow-pipe as it leaves the boiler, and with the return-pipe at the other end of the house. Both ends of the trough are made water-tight round the rain-water pipe. At the middle of the house a brass tap is fitted into the close-pipe which fills the trough, and can be adjusted to let water sufficient escape into the trough to just keep it full, and the small pipe nearly immersed in water. The supply to the boiler being of course on the return-pipe, is spoken of already, and by means of a ball-cock. This is the most satisfactory steaming-apparatus we have ever tried; it is simple, requires next to no attention, and the water heats regularly the whole length of the house. In open gutters without the small pipe, we have always found a glut of steam at one end, and next to none at the other, in long houses. The arrangement, besides, is equal to another row of 4-inch pipes.

Space forbids us to say much of boilers. We have worked conicals, cannons, single and triple retorts, saddles, upright tubulars, cruciforms, &c.; and we have some at work yet very much the shape of a butcher's pickling-tub. The last-named are perfectly absurd, of course, holding nearly as much water as all the pipes. Some of the others named are good. The upright tubulars are very powerful, but expensive, and require deep stokeholes. Upon the whole, for cheapness, efficiency, and safety of construction, we give the palm to Meiklejohn's cruciform. Various materials are used in constructing boilers, such as cast and malleable iron and copper. The latter is expensive, but marvellously effective, durable, and safe; and in our own case, we are superseding others with them, and in simple single retorts, 6 feet long by 2 feet in diameter over all. For amateurs, who only require to heat small houses, we know of nothing so efficient and cheap as Meiklejohn's amateur's retort. Fourteen years ago we heated a late vinery 63 feet long with one of these, and it is yet doing its work well. As to valves for stopping and regulating the flow of water, we have had numbers in use, but we consider Messenger's patent valve the most efficient, simple, and least likely to be out of repair of any we have tried.—(*The Gardener.*)

THE GLADIOLUS.

Just a few words in respect to the query put by "Stiff Soil," page 485, and the answer it has called forth.

It appears to me that the main fault does not lie in the ill-health of the bulbs, although I admit that it is impossible for diseased roots to produce good spikes of bloom. I should imagine that "one of our greatest English growers" would avoid sending out bulbs that were unhealthy, and, if such were the case, it is possible that he was not aware of it.

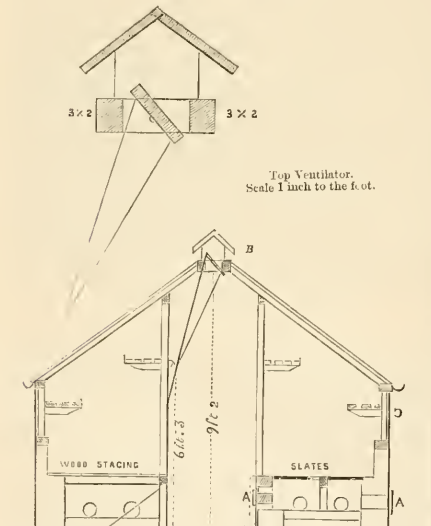
It seems that the inexperienced, and the experienced as well, have got hold of an idea that the Gladiolus is subject to an incurable disease, and this idea being strengthened by some of our principal writers, I fear it will be a long time before it is eradicated. I do not believe such is the case. My experience tells me that bulbs planted in soil which has previously had thick dressings of manure, decay and die prematurely; but that when planted in a moderately rich soil, and when coming into bloom, stimulated with weak liquid manure, they rarely show any unhealthy symptoms. The Gladiolus is like any other bulb, the older it gets the more exhausted is it, and the quality of the flower of course decreases with the degeneration of the plant. Let this idea of hereditary disease be destroyed in the minds of the public, and this genus of plants will yearly become more popular, and be much more extensively grown.

I expected the price of the Gladiolus bought by "Stiff Soil" would be questioned, but not one single word do his advisers say about it. Probably the bulbs grown were low-priced varieties, and if so, how is it possible to expect them to throw up

fine spikes? But if "STIFF SOIL" did have show varieties, for which, of course, he must have paid good prices, he did right, after all his care and attention, to look for some decent spikes amongst them. I have always observed that the bulbs for which 3*s.* 6*d.* and upwards is paid, invariably produce the best flowers. "First get the goose, and then cook it." I wonder what sort of spikes "STIFF SOIL" expected? Wonderful spikes, perhaps, after his great liberality towards them—equal to those we see exhibited by Messrs. Kelway year after year. If his bulbs have spots and black marks in them indicative of disease or decay, surely one man can see them as well as another? It is unnecessary to send a sample of them to any Gladiolus physician for his diagnosis of it. Allow me to give "STIFF SOIL" a little advice upon this matter. First procure good varieties, which he will find, if he refers to any of our English lists, depends upon the price charged—the higher the price (excepting the improved Continental varieties) the better the flower—and having carried out the advice given him by "D., *Deal*," and also the instructions to be found in the principal catalogues, particularly Messrs. Kelway's, of Langport—"*Attends pour les effets, espérant pour le mieux.*" May "STIFF SOIL" have a better report to give us twelve months hence.—EXPERTO CREDE.

BEDDING-PLANT HOUSE.

I SEND a sectional drawing of a small bedding plant-house which I have put up here on an economical plan—that is, economical in point of expense, and economical as regards space, all the plants being fully exposed to light. There are two shelves carried all the way round, one of which, the centre shelf, is wide enough for four rows of 4-inch pots placed cross-



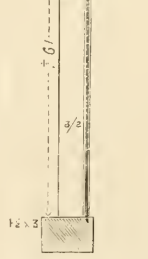
Top Ventilator.
Scale 1 inch to the foot.

Section of House. Scale one-quarter inch to the foot.

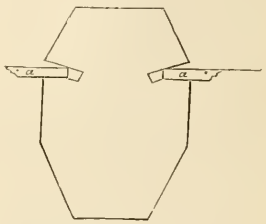
ing each other; the outer one is for three rows of pots. The plants on the shelves are easily watered by a small step-ladder from the central path. I use no putty and have no laps; the glass in the sides (marked c in the section), merely slips into grooves, the upper groove being made seven-eighths of an inch deep, the lower one three-eighths. The glass is slipped up into the upper groove first, and allowed to fall into the lower one. The glass for the rafters and sides is all of one size—20 inches by 16, and is 21-oz. fourths. The upright side pieces, 3 inches by 2, which support the upper piece of wood, 3 inches by 3, on which the ratters rest, are set back 1 inch on the wall-plate, so as to allow the glass to slide freely past them in the groove. The glass is continuous on the sides from one end to the other, the squares merely butting one against the other. This prevents all necessity for sashbars. I cut a nick in the bottom groove in the centre of each pane, to allow rain to drain out of the groove. The panes of glass in the rafters are pushed up from the bottom, and butt one against the other. They are fastened at the bottom by a bent galvanised iron wire pin, which is screwed on the inside of the upper pan 3 by 3, so that at any time in case of fracture the pin can be unscrewed and all the glass taken out. The spouts are fixed in the same way by strong iron crooks bent over to the top pane and screwed on to the inside.

Spout.

The water from the roof is carried into a tank made the whole length of one side of the house, by cementing the outer wall, and building an inner wall to carry the staging. The staging over the tank is of slate, with two rows of hot-water pipes confined in the chamber underneath. Sliding ventilators, as A A, are put into the inner and outer walls. If both ventilators are closed, the space over the water-tank acts as a hot-air chamber, and keeps the slates at a temperature of from 90° to 100°. The heat is, however, entirely under control by means of the double ventilators.



Side C, 1 inch to the foot.
Outer line glass.



Section of rafter, 3 by 2 inches. A A, Glass.

On the opposite side the staging is open woodwork, laths 3 inches by 1 inch, half an inch apart, and nailed together in 4-feet lengths. Two rows of 4-inch pipes, one flow and one return, are supported by the wooden staging, by wood pieces from the uprights into the wall. These wood pieces are 4 feet apart, and gradually rising 1 inch at every upright from one end of the house till the pipes reach to the highest point of the flow, under the slate tank, on the other side.

The house, owing to want of space, is only 25 feet long, and contains a little over 90 feet of pipe; but the flow is so perfect that there is hardly any perceptible difference between the heat of the flow and return pipes where they enter the house.

The boiler-house is at the opposite side of a path 5 feet wide, at the end and as a continuation of a five-light frame, the flue from the boiler heating the frame; the boiler, a common small saddle-back, properly set, the fire playing through and all round the boiler. I have not sent a ground plan, as there is no necessity.

The shelves are made of laths 3 inches by 1 inch, screwed on to light flat iron bars, so as to be moveable in sections, and to be taken out when required; they are supported on wood brackets tenoned into wooden uprights. The water-tank is made with a slight fall to the end farthest from the door; and under the staging, which returns at the end, a small cistern is made, about 2 feet square and 2 feet deep, to dip a can into,

the cistern being supplied from the tank by a tap. As there are two rows of hot-water pipes over the water-tank, it helps to keep the rain water during the winter at the temperature of the house.

The ventilation under the wood staging is through openings in the brick walls, with moveable shutters hung on hinges and regulated by a string. The upper ventilator is a fixed pent with moveable shutters hung on pivots, and also regulated by means of strings. The ventilation is in all respects very efficient, and there is always a slight current of air passing under the glass, as the glass in the rafters does not touch the wall-pan by three-eighths of an inch. This prevents water accumulating on the wall-pan, and any rain which finds its way through the butt joints runs down the inside into the spout, and though there are no laps, the house does not leak in the wettest weather. In summer weather the front row of glass can be taken entirely out and Nottingham netting put in its place, or one or two panes can be taken out and the others separated. I frequently do this to harden plants previous to bedding-out.

The house runs east and west, but I should prefer to put it up north and south. I never use any shading, but after the first or second week in April put a slight wash of milk and whiting with a very little paste outside on the south side; this when once dry will resist almost any amount of rain, and breaks the scorching rays of the sun without interfering in any way with the light. I do not claim any particular novelty, but I have never seen any house exactly like it, and I built it for the sake of accommodating as many plants as I could, when potted-off, in a small space.

The house is only, as I stated, 25 feet long and 10 feet wide outside measure, but I can put 2500 Geraniums in 4-inch pots into it. I built it before I had seen any other house without laps to the glass or putty, and I still like the form of rafter better than any other I have seen, as by ploughing the groove at an angle and then taking a slight shoulder off with the chisel, a groove is left under the glass, down which any water which is drawn to the rafter runs, instead of dripping into the house. I have never seen any drip whatever from the rafter. I can recommend the house to any amateur who wishes to have a generally useful plant-house, and especially to those gentlemen who expect their gardeners to turn out large quantities of bedding plants, and who have hitherto provided no additional means. There is so much light and good ventilation in a house of this kind that I find, practically speaking, plants from it never require hardening-off. Another great advantage is, that the whole of the glass can be removed in a very short time for repainting or other repairs; and the paint can be laid on by any ordinary hand, as there is no glass to smear, and the work is consequently very quickly done.

I keep plants growing in a house of this kind all the winter, and I never find they get the least drawn-up or spindly. Damping-off and evils of that sort are unknown, unless there is no fire heat in November and December, when I maintain nearly all plants raised out of the open ground and potted-off in October must suffer if not allowed to grow. I find the same cry constantly repeated, "Don't water! Don't water! Don't let plants grow in the winter! All growth must be spindly and bad." I feel sure, however, that with properly constructed houses common sense will tell any gardener it is easier to preserve a plant in health by allowing it light and air, water and heat, than by keeping it stagnant in cold, and dark, and damp; and a little common sense and attention, which are the great secret of success in gardening, will soon teach gardeners what degree of warmth and moisture is requisite for the various tribes of plants. For instance, it would be absurd to treat a Calceolaria in the same way as a Geranium, or a Chrysanthemum in the same way as a Verbena; and yet I have seen Calceolarias in pots dust-dry, flagging from want of water, and been assured by the gardener that they were damping-off, instead of which they ought to have been put into a pail of water for half an hour.—C. P. Peach.

MRS. PINCE'S MUSCAT.

I was glad to see the notice of Mr. Donaldson's success with this Grape. I think it has been most unfairly run down. It has always done well with me, and was admired by hundreds this season. I think it requires a little care in setting. When in bloom my man always touches the flowers with a camel-hair brush, and every bloom sets. This is done on two or three different days with almost every kind of Grape, as I like to leave nothing to chance, and the trouble is very trifling. There are few kinds, except the Black Hamburgh, which do not benefit by this operation in some seasons, though in others they may set their fruit well without any trouble. The brush we use is as large as a painter's middle-sized painting brush, and the flowers are just gently touched with it to distribute the pollen.

With me Mrs. Pince is larger in the bunch than Lady Downe's, and keeps better. I think Madresfield Court is the best of the new Grapes, but it does not keep so well as I expected. It is a grand Grape both in bunch and berry, and of fine flavour; but it will not, I think, keep more than a month longer than a Black Hamburgh in the same house. If it does not keep so well as was expected, many will be found to deny its other good qualities. To be puffed absurdly, and afterwards run down unfairly, seems to be the fate of all new Grapes. After all, it is better for people to give their experience, as the special requirements of a variety may thus be elicited. A man may miss his way in the cultivation of a new kind of fruit without being exactly a fool.—J. R. Pearson, *Chilwell*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Keep *Cabbage*, *Cauliflowers*, and *Endive* thoroughly clear of all bad plants and dead leaves. Sow in well-prepared situations the second crop of *Peas* and *Broad Beans*, a few of which should be sown in boxes, pans, or flower-pots for fear of frost or vermin. The Peas and Beans that have made their appearance above ground should have a short-toothed iron rake passed across the rows to break the surface-crust of the earth. A warm border should be chosen for sowing early *Horn Carrots* and short-top *Radishes* in neat drills, alternately. These drills may be formed by means of a triangular stick, and should be covered-in with sandy soil, and protected with such materials as hoops, mats, fern, &c. Sifted dry dust, charred tan, or any other charred refuse, should be shaken amongst them as they progress. It is astonishing what robustness and vigour this imparts, besides keeping out the frost and preventing shanking and cankering.

FRUIT GARDEN.

Proceed with planting. Prune and nail wall trees. Dress in suitable weather those fruit trees that are infested with moss, lichen, or scale. Prune, train, and tie-in neatly all espalier trees, and clear away to the char heap all refuse that will not readily decompose. Fork among all fruit plantations, applying some manure, if possible, about the roots of the trees. Where the nailing of Pear, Plum, and Cherry walls is finished, form and chop out the alleys at convenient widths, and fork up roughly the spaces left next the wall, spreading some sifted cinder ashes thinly on the alleys. This is the means of keeping the surface of the alleys from becoming bound by traffic, and makes them at all times clean and comfortable to walk on, but scrapers should always be placed at convenient distances. If frost prevails, stir up the soil well with the hoe, or fork close under the walls and fences. Such places afford a ready refuge for slugs and other vermin to hide away in security, and shake a little quicklime over the earth thus disturbed.

FLOWER GARDEN.

Make new walks, flower-beds, and renew the soil in old ones, if the weather permits. Holes for planting choice shrubs or trees may also be prepared, by removing the bad soil and replacing it by a compost suitable for the plants; and even where trees are planted and not growing well, the soil may be carefully removed from the roots and replaced by better material. Where any of the beds require fresh soil, it should be made ready to be wheeled on when favourable weather for such work occurs. Fresh soil is, in most cases, preferable to manure as a dressing for flower-beds, which is too invigorating. On poor soils, and where neither fresh soil nor decayed leaves can be had, a moderate dressing of well-rotted farmyard manure will, however, be useful, but this should be well mixed to the full depth of the bed, and not left in lumps near the surface. Avoid getting upon or working the ground when it is in a sodden state.

GREENHOUSE AND CONSERVATORY.

About 40° is a good temperature for the conservatory when not attached to sitting-rooms, and only used for the purpose of wintering large specimens without plants in bloom; but where a supply of stove plants in bloom is constantly kept up from a forcing pit, the best heat is 45°. Cinerarias should be watered and protected from the attacks of insects. Chinese Primroses are very ornamental, and ought to be cultivated.

In regard to soil, two parts rough leaf mould and one of well-decayed cow dung, with a little sand, suits them best, the whole being kept moist. Large plants of Rhododendrons or Camellias that have been some time in their pots or tubs, should receive weak tepid liquid manure. Forcing pits should now be in full activity to furnish plants in bloom. If required in sitting-rooms, care should be taken before they are removed there to gradually harden them for a day or two, either by placing them in the conservatory or intermediate house. Hyacinths should be protected by a frame as they begin to grow, remove the plunging material down to the surface of the pots to prevent them rooting upwards. Mignonette will require attention to keep it from damping. As all but forced plants are now quiescent, the temperature of plant houses should fall to the lowest point consistent with the safety of their various inmates, as nothing can be worse than a high temperature at this season. Keep up a regular succession of plants to bloom through the spring by bringing forward the stock of forcing plants as wanted. Roses, both dwarfs and standards, Honeysuckles, hybrid Rhododendrons, and Azaleas, with a host of other plants, will enable you, with the addition of the usual occupants of the house, to make a brilliant show through the spring. Hyacinths, Narcissus, Tulips, Lily of the Valley, and other plants of the above class, must be duly forwarded as required. Hardwooded plants will require a dry pure atmosphere to prevent mildew and damp.

PITS AND FRAMES.

Remember that in the absence of sunlight, plants increase by preying on the materials stored up in their system, and are thus injured as regards early flowering and compact habit of growth. Admit air freely amongst the plants in the pits and frames as long as the weather continues as it is, but be careful that the air is dry. Take advantage of bad weather to wash-up and arrange the stock of dirty pots, to paint any tubs, baskets, wires, &c., out of use. Prepare labels of various sizes, forked sticks for pegging-down plants in the flower garden; look over the stores, and provide whatever may be required for the season's use; also get in a supply of the various loams, peat, &c., required for spring potting.—WILLIAM KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

CONTINUED to dig, trench, and clean, and on a fine day hoed among some young Cauliflower, Spinach, Onions, and Lettuce, which last have hitherto stood well. As our first crop of Rhubarb had come in well, we placed some more in the Mushroom-house to form the third crop.

Trenching and *ridging* may be done during damp weather, but not when the ground is soaked with moisture. Some persons we know, thinking to give the roots a greater facility of penetrating, and hoping to secure a more uniform supply of moisture, have trenched down the good surface soil, and either turned up a hungry gravelly soil, or a hungry, unmanageable, marly clay. The surface soil in these instances was but from 10 to 14 inches deep, and in striving to get a moveable tilth of from 18 to 24 inches, they incurred a great deal of trouble and immediate loss. In a deep soil deep trenching is advantageous, but in a thin one a little of the subsoil must be brought up every year to increase the tilth. All heavily cropped ground should be recruited from the subsoil by mixing 1 inch of this with the surface soil, and loosening some 6 inches more, and letting it lie at the bottom. This last should be allowed to remain for two years, after which it may be made part of the upper soil, and the process repeated upon the new subsoil. It is better not to be in too great a hurry, or else in a rash moment you may trench too deeply, and make the ground utterly barren, as we have seen it ere now, when there is no remedy but re-trenching. Trenching or ridging-up very roughly has generally been thought to be the best preventive against snails and slugs, but we think that a smooth surface is more effectual in this respect.

Now is the time to prepare ground for Asparagus, Sea-kale, Rhubarb, and Onions. A sprinkling of quicklime, tar, or lime from the gasworks, if used early in winter, is very useful in keeping off the grub from Onions; but care must be taken to have all noxious fumes arising therefrom dissipated before sowing. We would not use dung for the ground in which we intended to plant, but rather lime. At the bottom of a piece prepared for Carrots we have placed a good coating from the rubbish heap, and should like to give it a lime-dressing if we could. In the case of too rich soils, lime has been applied with the most satisfactory results, since it acts on the manure so as to make it serviceable to the plants. I remember a case where the ground had become barren from excess of manurial matter. The stiff surface soil had 3 inches of the subsoil incorporated with it, was trenched and ridged, and over the whole, on a fine day, was strewed half an inch of quicklime, afterwards gently mixed with the soil. Before sowing, the ground was re-ridged and cross-ridged, care being taken to keep as much of the lime as possible near the surface. The result was one of the finest crops of Carrots I ever saw. Lime will be of little benefit to poor soils, as it consumes what little organic matter they do possess; but sandy soils will be improved by the application of lime, which in their case is only to be excelled by clay or marl.

FRUIT DEPARTMENT.

Have had some newly-emptied houses cleaned and lime-washed, in order to be ready for forcing. Pruning, planting, tying, and nailing are better done now than two months later. A few light half-inch boards will be found very useful in keeping the feet clean whilst pruning, and likewise in working among flower-beds in wet weather.

ORNAMENTAL DEPARTMENT.

A light wooden roller from 10 to 12 inches in diameter will now be found of great service. Turned up some flower-beds, and cleared away dead leaves. Some of our plants in houses are showing signs of ill-health, which is attributable either to the fumes of fresh paint or gas. I much prefer a lamp to gas, but if having the latter is unavoidable, burners with reflectors at the top of the roof, inside or outside, are next to be desired. Brought in more soil to be aërated and warmed, with which old Mushroom dung, also useful for top-dressing, may be mixed if it no longer contains any spawn. Earth for potting should not be too dry nor yet too wet. We are at present potting Pelargoniums, as they require thinning-out. We shall not again stop these, nor give them a very large shift for early flowering. Sandy fibrous loam, with a little decayed manure, will grow them well; but rather than put an excessive amount of manure, which causes too strong foliage, in the soil, use manure water to them when the flower-buds are set. A rich top-dressing is also very beneficial. In such dull weather use no more fire heat than is absolutely necessary, and give air according to the hardiness of the plants. In foggy or close weather give no more air than prevents the accumulation of vapour at the top of the house. Use water rather above the temperature of the house, and take care not to spill it about. —R. F.

TRADE CATALOGUES RECEIVED.

Dick Radclyffe & Co., 129, High Holborn, London, W.C.—*Catalogue of Vegetable, Agricultural, and Flower Seeds, &c.*—*Catalogue of Farm Seeds, &c.*

W. Bull, King's Road, Chelsea, London, S.W.—*Retail List of New Plants.*

J. Scott, Merriott, Crewkerne, Somerset.—*Catalogue of Fruit Trees.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (*R. D.*).—We do not know the publisher. We should probably be able to ascertain if you said who was the author.

SELF-ACTING FOUNTAINS (*J. R.*).—We are informed that they are manufactured by Messrs. J. Brooks & Son, Sheffield. They would pay for fully advertising.

VINE GRAFTS (*J. M. O.*).—Thanks for your obliging offer. We have not the variety you name.

ROYAL MUSCADINE VINE—SALT AS A MANURE (*H. Foy*).—Doubtless your Vine suffered from being shaded by the Black Hamburgh; but a young Vine seldom does well when planted in a border already occupied with other Vines. You would succeed better were you to inarch the Royal Muscadine on the

Hamburgh, and see that the young rods are fully exposed to the light to ripen the wood properly. Salt applied at the rate of half a peck to a rod of ground will be of much benefit to vegetables, and also to your flower border.

Planting Vines (*Ignoramus*).—You purchased fruiting and not planting Vines. Canes such as you describe would carry a crop of fruit next season. If you plant them as permanent Vines, cut them back to 9 feet at once, and plant them out in March. When the buds are fairly started rub off all except two or three at the base; these you must train up to the apex of the roof. Pinch all lateral shoots at the second leaf. As your house is span-roofed, why not plant on both sides? If you cannot do this, then you must train the young rods over from one side to the other. The second year, if the Vines have done well, they will bear a light crop of fruit—from two to four bunches on each rod. As soon as the leaves have fallen the canes should be cut back, the weakest to 8 feet, and the strongest to 6 feet from the bottom of the rafters. If your house is used as a greenhouse in summer, the Vine rods should be 5 feet 6 inches apart; if used only as a vinery, 2 feet 9 inches is the proper distance.

Planting Vines and Making Vine Border (*Philip Barker*).—We would not make an outside border the first year, and only half of the inside one, making up the other half inside at the end of the second year; two years after this we would add 6 feet to the outside. "A barrier of slates" would not prevent the roots from running through to the back wall. It would require a brick wall on a solid foundation. You could manage it by raising a wall of turves as you filled-in the new border, and leaving an open space between this and the old soil. Vines will do no good on the back wall after the roof is covered with bearing wood. Six plants will be sufficient for a house 30 feet long, two rods trained up from each plant; it will leave them 2 feet 6 inches apart, which is as close as they ought to be.

Iron Pipe for Flue (*Flue*).—We are sorry we cannot help you much All iron pipes used as flues are apt to have this dark sticky fluid formed on them in exact proportion to the dampness of the weather and the fuel. Sometimes, but not so often, it appears on brick and earthenware tube flues. We advise you to burn some dry wood in the furnace to dry up the condensation, and then use fuel in a drier state than usual. It would also be well to have a short pipe at the lowest level to slip over the ends of the other two, and by taking this off or slipping it along you could clear out the matter by a pole or small hoe.

Pit Converting to Propagating House (*A Young Beginner*).—We have no doubt the plan you propose would answer well, but you must have means to let the heat rise to warm the air of the house. If you have tanks on the flue, you would need corks attached to small rods to show when the tanks were full. We have very lately described the modes of doing all this with a flue. As you mean to retain the flue, this is the way we would do it:—Instead of the pit of 7 feet in width, 7 feet high at back, and 3 feet high in front, we would sink the pit 6 inches more, run a 4-inch wall, with piers of 9 inches, 2½ feet from the back wall, raising that to within 3½ feet of the glass. That would form your pit. Then take a 9-inch flue through the middle of it; brick-on-hed for a yard from the furnace, brick-on-edge the rest of the distance, and carry it back in the pathway, the top of the flue forming part of the pathway. You would thus command bottom and top heat without any trouble. All round the flue in the bed we would pack clinkers and brickbats openly, and cover them and a few inches over the flue with smaller stones, and then fine gravel. On each side of the flue have upright drain pipes, so that you can damp the stones and rubble, not the flue, and have plugs of wood for these upright pipes. Four or five of the uprights should stand on each side, and the base end should rest on a slate, so that the water might be dispersed over the stones. Adiantum farleyense should seldom be in a temperature below 60°.

Where to Move to (*A Yorkshireman*).—As you have spent four years at nursery work, we think that you had better remain at that than prepare for holding a place as a gentleman's gardener, in which case you would have a good deal to learn. Much, however, depends on your own feelings with regard to the subject. An intelligent temperate man will command good wages in a nursery when his character and capabilities are fully established, and he may ultimately set up business for himself. At all events, he will be able to act more independently than if he were a gentleman's gardener. Nevertheless, in the latter case, though not free from drawbacks, he will have no trouble with money affairs—one of the most disturbing circumstances to many when they first commence business.

Cucumber (*Vegetarian*).—Write to Messrs. Rollisson, Tooting.

Distinctive Characters of the Rose Classes (*An Inquirer*).—Your query is not easily answered. Many florists place a Rose in different classes, and many would be puzzled if asked to state the characters of some of the classes. If any of our great Rose-cultivators will furnish us with the distinctive characters of the Provence, Bourbon, Noisette, Hybrid Perpetual, and other classes, into which florists divide Roses, we and many of our readers will be much obliged.

Colour of Peas (*H. C.*).—The colour of Peas is reckoned from their condition in a dry state, the white, as a rule, being the smallest, and of a paler colour when boiled than blues, which are also of better flavour. The green are good in colour when cooked. The blue and green are generally better croppers, but this does not invariably hold good, as some of the whites are excellent both as regards cropping and quality.

Stopping Pelargoniums (*A Young Exhibitor*).—For flowering in June stop them early in February, and the Fancy sorts at the same time. Your treatment is correct.

Small Birds Attacking Buds (*Constant Reader*).—Dress them with a mixture of lime and soot, brought to the consistency of paint by adding 2 ozs. of soft soap to a gallon of water. This should be done about February, and is also a good preventive of insect pests. We have found it also desirable not to prune until the buds have begun to swell. We have found black worsted or cotton stretched from branch to branch, so as to form meshes about 3 or 4 inches wide, keep off birds when other means failed. Strips of glass about 3 inches long and 2 wide, blackened on one side, suspended from the shoots, are useful for scaring them.

Electricity (*J. Wilson*).—It will not make plants grow without warmth &c., nor can we without diagrams explain how you could make a galvanic battery.

Names of Fruits (*J. D. Gillingham*).—2, Chaumontel; 2, Beurré Langelier; 4, Fearn's Pippin; 6, Cowarne Queening; 7, Pile's Russet.

Names of Plants (*A Ten-years Subscriber*).—Your Oncidium sent last week appears to be O. altissimum. (*Mr. H. Durlin*).—Pellæa adiantifolia. It is not a climbing species. The frond sent is quite exceptional in having its rachis curved.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE OLD AND THE NEW YEAR.

We have somewhat varied our routine. Formerly we addressed our readers on the last number of the old year. The retrospect is not so cheerful as the anticipation. We had to do with the past, and now we are disposed to draw on the future. The latter is always gilded, the former has suffered from wear and tear. The past is somewhat stale, flat, and unprofitable; the future

"Hails in its heart the triumphs yet to come."

Yet we would not discard the past; it tells us of another prosperous year, of old ties still unbroken, of constantly-recurring names that are "familiar in our mouths as household words," and we trust that they, like ourselves, are grateful that we are spared to hail the advent of Eighteen Hundred and Seventy-two. We have had halcyon days. We have glided down the past fifty-two weeks with few, if any, storms, and our bark enters the port with canvas undamaged, and with a tried and trusty crew.

Some remarks on the past may be expected, and we shall not withhold them. As faithful chroniclers we will briefly notice those things with which we have been brought in constant contact.

Dorkings have remained stationary as regards weight, but it must be recollected there is a limit to everything. In the last few years they have increased (we speak of exhibition birds) from 2 to 3 lbs. each. They still form one of the largest classes at shows, and they sell readily. The fault we have to point out is the prevalence of spurs outside instead of inside the leg. This should be avoided. In this, as in many other breeds, although size is a great desideratum, it must not be gained by the sacrifice of other properties.

Spanish make no progress either in numbers or quality. They are not equal to those we had years ago, nor are they so distinguished for those merits that amateurs look for. We should be sorry to see a marked decadence in these beautiful fowls. They are the townsman's birds. Their constitution is of iron; they will live in any space however confined, and when eggs are sold, as they should be for general purposes, by weight, they will tell their tale in the balance-sheet. It is true they are not sitters, but few dwellers in towns have convenience for rearing chickens.

Our good old friends the Cochins increase and prosper; they deserve it. No fowl has kept the word of promise more than these have. They never ail anything, their chickens are hatched as hardy as young crocodiles, they are not wanderers, and they do not easily take offence. The pullets lay at an earlier age than almost any fowl; and as it no longer costs a good hunter, or a six-roomed cottage replete with every convenience, to buy a cock and hen, we are not surprised that they are extensively kept. Viewed as show birds, they have not been kept to the standard of former years. The hideous vulture hock has been overlooked, or allowed to be palliated by a little extra feathering on the leg or middle toe. A mealy wing in a cock has been declared an abomination, while stained hackles in pullets have been allowed to pass unquestioned. It was the work of years to get rid of the marked hackle, but the vulture hock was unknown till recently. Many thousands of birds, faultless save for the hock, have been, and still are, killed every spring.

These remarks will in some measure apply to the next review, that of the Brahmas. These birds have at last outlived all opposition, and now form the large class at most exhibitions. They are truly valuable fowls, ridiculously hardy, careless of confinement, moderate eaters. The facility with which they are bred to resemble each other in every particular point, has long since disposed of the idea they were a composite breed, or an offshoot of the Cochins. If we were asked for a fowl calculated to live and do well in any place or under any circumstances, we should certainly name the Brahma.

The beautiful Polands have been shown in larger numbers during the past year. The Silvers have been especially remarkable for their high merit. Game have been everywhere perfect. Some critics complain they are now bred too long in the leg, but we cannot help thinking they are very perfect, and

we shall, we believe, be in strict order when we express our opinion that no other class shows so many faultless birds. The exhibitors seem to understand their birds, and the condition in which they are sent proves it. Many of the old varieties that were commonly seen thirty years ago have almost disappeared, and the large entries are made up of Black Reds, Brown Reds, and Duckwings. These last are the weakest, and do not keep pace with the others. Hamburghs barely hold their own. The Silver-pencilled have certainly deteriorated. The Golden in both Pencilled and Spangled classes have been superior to the Silver. The French breeds may have something to do with this. They lay almost as many eggs, and they lay them much larger. The Houdans and Crève-Cœurs are good birds. They are excellent for the table, and are very hardy. Their fellow breed, the La Flèche, finds few admirers. We are not surprised; they have not good constitutions. We believe the two former will make large classes, but we do not think the latter will ever bring a sufficient number of entries to pay for the prizes offered.

A revolution has almost taken place in Bantams. The once-popular and numerous Sebrights are fast disappearing. It is rare to see a dozen pens of them, even at the largest shows, and unless some one come to the rescue and keep up the manufacture of them, it will be difficult to keep them fair specimens of these beautiful birds. The Blacks and Whites, taken as a whole, have hardly been as good as formerly, although some very good pens have been shown. All the energies of Bantam-breeders appear to be centred in the Game. They not only show in large numbers, but their quality leaves nothing to desire. We have the Black Reds, Brown Reds, Duckwings, and Piles. They do not confine themselves to feather, but they faithfully produce the Game cock in all his points. In the varieties of Bantams, some introduced from Japan a few years since show in tolerable numbers. The Cochin Bantams would appear to be difficult to breed, for although a ready sale at very good prices awaits them, yet they do not increase in numbers. There are also Cuckoo Bantams, and we are promised some Dorkings for next year.

If we may believe the entries at the different shows, the Aylesbury Ducks are losing ground, compared with the Rouens. These latter are heavier and far more numerous. It would be a great mistake if the former were allowed to degenerate. They have properties few others have, they lay very early, and they fatten at an age when others are only beginning to grow.

Geese have been shown well, and the birds have been very heavy. We have no average increase to mark as compared with last year, but it must be borne in mind that the weight of these birds has more than doubled in the last twenty years. Everywhere the increase in the numbers of Turkeys entered for competition has increased, and so has the weight of the birds. The Americans have lost somewhat of the beautiful plumage they had, but they have gained largely in weight.

It has been a harmonious year. There have been no great questions of division among the followers of this healthy and humanising pursuit. Judges have been indulgently treated by those who judge their awards. They are only now and then attacked. It is admitted by many that at even some of our largest shows they have little light and less time. Some of the critics remind us of Mr. Boatswain Chucks, inasmuch as they begin by all sorts of little amenities, and end by an onslaught. "To every man his opinion." We have endeavoured, and we shall continue to do so, to practise the strictest impartiality. We rejoice to believe that the line we have adopted meets with the public approval and support. We are not unmindful of the obligations we are under to our many readers. We tender them our hearty thanks. Endeavouring to realise the ties that bind us to all interested in our weekly issue, we say to every one of them in the fullest sense of the words, May they have

A Happy and Prosperous New Year.

WOLVERHAMPTON AND PORTSMOUTH SHOWS.

I observe that the Wolverhampton and Portsmouth Shows clash with regard to date, or, at least, exhibitors cannot exhibit the same stock at both. Now that is to be regretted, as both schedules offer liberal prizes, and I have no doubt they would each have a very good show if it were not for their being advertised to take place at nearly the same time. I should think that the Portsmouth Show could be held a week later, and the date for entries to close could also be later. A special advertisement might be inserted as to change of date. To prevent poultry being sent at the date originally advertised, a printed post card could be sent to all those who entered up to 25th January, which is the date given for entries to close.

I am aware that this will cause trouble and expense, but I think the entries would be far more numerous and so make up for this. I feel sure the Committee will not mind that, as long as they can bring the Show to a successful issue. If anything in the matter can be done, it must be done at once.—One that would like to exhibit at both.

SELLING CLASSES—A SELLING SHOW?

The remarkable success of the selling classes at the Crystal Palace proves to my mind that they supplied a want keenly felt by both breeders and buyers of good poultry; and the quality of many of the birds also demonstrated conclusively that moderate prices do not forbid the entry of really fine specimens. But, in common with many others, I confess I was strongly struck with the absurdity of the whole affair as at present managed, and especially as it bore upon the character of the judging. I conversed with both the Judges, and both fully agreed with me as to the utter impossibility of awarding any moderate amount of prizes in such varied and immense classes. Even with regard to mere numbers, it may be sufficient to state that one class numbered 126 entries, sufficient for three classes at least; but beyond this, when all breeds are thus jumbled together, how is it even possible that anything in the shape of judging can be done amongst birds in such ludicrous variety? As one of the gentlemen upon whom the enviable task devolved remarked to me, "When a man comes to me and complains, 'Why haven't you given me a prize? Arn't my Bantams as good as Mr. So-and-So's Cochins?' What can I say to him? Perhaps they are as good, but how can I compare two breeds so totally dissimilar?" Anyone can see the reasonableness of this complaint; and considering how these giant classes swell the coffers of the Show, not only through entries, but from the commission on sales, it becomes absolutely necessary in common fairness to all parties that a remedy should be found. I would suggest that each class might be subdivided as follows:—Large Asiatic breeds—to include Malays, Cochins, and Brahmas; table breeds—to include Dorkings, French fowls, &c.; other breeds not Bantams; and Bantams to have a class to themselves. Other general classifications might be substituted; but I am well convinced that without some such remedy as I have suggested for a really crying evil, this interesting feature of the Crystal Palace Show will "go down."

But the success of these classes has suggested to me whether even they have supplied a want, which is so evidently felt, of procuring on the spot birds of really good quality at moderate prices. I do not think they have, and I do not think they ever will while the prices are so low. As a rule, I know by experience, that reliable stock birds cannot be bred and sold for two guineas—they cost more than that to produce. At all events the question set me thinking, the consequence of which has been a new idea, on which I should like the opinions of some readers of this Journal. It is, that it would be a good thing to have a Great Selling Show, some time near the end of the season, at which the limit of price should be five guineas for single cocks, and six guineas for pairs of birds; the prize birds to be sold by auction, and any excess divided as usual; the other pens to be claimed, with the usual precautions against owners claiming their own.

I believe whoever first takes up this plan will make a good profit by it; and I may suggest that it would accomplish many desirable ends. In the first place, while these prices would, in my judgment, be quite low enough to meet the views of fanciers, I have no doubt there would be no want of good birds. In the second place, at the end of the season owners would have a good chance of clearing off much stock, without the "alarming sacrifice" our present selling classes often involve; and the classes would be filled by real breeders sending good birds. In the third place, such a show would provide the field, which a recent correspondence seemed to desire, in which fairly good birds might make a good fight without the dread of being outdistanced by the champion birds of the year; and this object would be obtained without the evils of handicapping or the other plans then suggested. Lastly, at a price moderate, and yet enough to repay breeders for producing them, really valuable stock might be secured.

I may, perhaps, say that I have named this idea in private to many experienced fanciers, all of whom have received it

favourably; and I believe that if fairly carried out such a show would be a feature of the year. But it is because I think it would serve a really useful purpose, that I propound it to the fancy at large.—L. Wright.

EXCLUDING DEALERS FROM EXHIBITING.

I have been waiting to see an answer to Mr. J. Ashworth's letter in your number of December 7th, in which he advises secretaries and committees of poultry shows to exclude all dealers, but no one having answered it, I ask space for a few lines. There are many societies formed, and many forming for the purpose of comparing birds, and for friendly competition amongst members only, and I believe in all cases the rules are very strict against admitting dealers. Now, if Mr. Ashworth will join these, it will do away with his objection to compete against dealers. At the same time I should be very sorry, and I am sure many others would be sorry, to see them excluded from our large shows, as by doing so we are robbed of half our victory when we win, for we could not but feel that our success was only partial when all were not allowed to compete.

The object of all large shows, such as Birmingham, the Crystal Palace, Manchester, is to bring together the best birds in the kingdom; this would be frustrated were Mr. Ashworth's advice acted on. He says, "Fanciers may buy the best birds dealers have at very high prices, and at the very next show the same dealers beat them completely." Considering he writes in the interest of real fanciers I think his letter a contradiction. Real fanciers do not buy birds to win. What credit is it to give, say, £20 or £30 for a pen of birds to win? The great pleasure and credit is when you can say, "I obtained those birds by careful breeding, and did not buy other people's work and experience to win." I am sure Mr. Ashworth does not object to be beaten with better birds than his own. I always feel pleasure in seeing birds superior to what I possess. It is a very difficult matter to say who are dealers and who are not. A dealer is one who buys and sells—do we not all do so? —Frank Graham, *Birkenhead*.

AMALGAMATION OF COLUMBARIAN SOCIETIES.

For the last ten or twelve years I have taken a leading part in getting up Pigeon shows, but latterly have been inclined to give them the cold shoulder, from a doubt arising in my mind whether open competitions were productive of good or very great harm. When Pigeon shows were first introduced the committees were formed of enthusiastic fanciers—business men, as a rule—glad to have a little relaxation from the worry of warehouse labour, and perhaps indulging in their youthful fancy, when the memory of boyhood and their "first pair" reproduced a pleasure they would fain realise again, by giving themselves and other fanciers an opportunity of meeting with each other, and in a friendly and honourable spirit innocently competing their birds. Now we find that this sort of competition has greatly verged into a complete mercantile speculation, and accompanied by all sorts of trickery and deception, by combinations and other unfair means, so that every society must now feel their labour, their time, and their money, is worse than thrown to the dogs. Changes have been made year after year in the hope that a better spirit of competition would ensue, but again and again the same sickening reflection after it has passed; and we find, as before, the bulk of the prizes have been carried off by some exhibitor, who, making it his business, enters one hundred birds, or may be more (though not always in his own name), and gives his whole time and mind to making it pay. We too frequently find an amount of deception practised, so artistically executed that from our best judges, not having the time necessary to detect it, the money goes. Medals, cups, and such like, are not wanted; "Money I want, never mind the medal," is the invariable request of the speculator. Can there be no alteration made to prevent our competitions going down altogether? for assuredly they will if carried on in this way, when the continual cry of these exhibitors is, "Give us larger prizes." "Do not charge so much entry money." "Those who get up shows should not exhibit, at all events, should not compete," and so forth. Again, however, the old feeling returns when a new idea is suggested by "A Columbarian"—the amalgamation of Columbarian Societies. This, I firmly believe, would answer the purpose, and I have no doubt "A Columbarian" will secure the gratitude and co-operation of all true-hearted fanciers to carry his new idea into effect, which having been seconded by "West Riding," I trust will be immediately acted upon; and if a preliminary meeting be requested of all secretaries who favour such a scheme, I have no doubt a very warm response would be the result.—A Willing Helper.

MANCHESTER POULTRY SHOW.

For eleven years past the Manchester Show has been held at the Belle Vue Zoological Gardens, and annually increasing in public estimation, has now become one of the most important meetings in the kingdom. The hall it which it takes place is not to be surpassed by any other building in the country. Though warmed artificially, the ventilation is perfect, the light amply sufficient and well-diffused, and the feeding of the birds and general attention such as must give entire satisfaction to even the most fastidious exhibitor, whilst it is impossible to speak too highly of the unvaried attention paid to the poultry. The Messrs. Jennison, who are the proprietors of the Gardens, having had a lifetime's experience in keeping in perfect health valuable animals among their own large collection, feel quite at home in all that relates to the proper attention necessary to a poultry show, even in case of any unexpected illness or misadventure arising to any of the highly esteemed birds entrusted temporarily to their care. There is not a doubt that a considerable number of the best pens of poultry on view, evidently almost exhausted from over-exhibition, will leave the Manchester Show in far better condition to that in which they were received at the time of admission. Indeed, it is very probable, not a few pens that actually were sent on from the Edinburgh Show to Manchester, would have succumbed altogether to this overtax on their powers but for the prompt and efficient treatment adopted by the managers at Belle Vue.

It is long since we saw so splendid a collection of all the leading descriptions of poultry as that exhibited on the 28th, 29th, and 30th of December. Grey *Dorkings* were an immense entry, many being shown in beautiful condition; but beyond question the hens and pullets were, as classes, superior to the male birds. Silver-Grey Dorking cocks were not true to feather, having partially white tails partially pulled, to prevent the eyesore being visible. The hens were excellent. Never were better classes of *Cochins* seen than on this occasion, but very many were quite beaten by continuous travelling and consequent hardships. The hens appeared, however, to struggle through these difficulties better than their male companions. Buffs, White, and Partridge-feathered hens of the highest character were abundantly shown. As to *Spanish* fowls, most certainly there has not been so good a collection as this brought together during the recently-ended year. Buyers for the best of these classes purchased extensively, and we have little doubt their speculation will prove a most remunerative one. The Dark *Brahmas* were really good, but many had been too much shown previously to hold their own in competition with birds fresh from the breeders. Light Brahmas, on the contrary, fell behind in quality and style, and excited but little public interest. *Game* fowls, Brown Reds and Black Reds more particularly, were one of the great features of the Show, and it will be seen by the prize list new names are becoming prominent. The Game fowls, almost without exception, were in exquisite condition. It is a remarkable fact that the *Game Bantams* were shown in very inferior health and plumage, or as a visitor very graphically observed when looking at them, "they seemed all worked out." The *Houdans* and *Crève-Cœurs* were most important and well-filled classes, far surpassing any previous show held in this district. *Hamburghs* were best in the Spangled varieties, and perhaps the Black ones are equally worthy of mention. All the *Ducks*, *Geese*, and *Turkeys* were of the most perfect character, and the fancy *Waterfowl* class embraced three pens of Whistling Ducks, as many Mandarins, and the like number of Ruddy Shell Ducks, Carolinas, as well and the like number of Ruddy Shell Ducks, Carolinas, as well as a variety of other interesting breeds. In cases where great merit was general the Messrs. Jennison, with their customary liberality, permitted extra prizes to be awarded, and no doubt in such cases an improved prize schedule in futnre years will result.

Dorkings (Coloured except Silver-Grey).—*Cock.*—1, J. White, Warlaby, Northallerton. 2, Miss Davies. 3, W. Harvey, Sheffield. *hc*, Hon. W. H. W. Fitzwilliam, Rotherham; T. Statter, Manchester; H. Yardley, Birmingham. *c*, Rev. J. G. A. Baker, Biggleswade, Beds. *Hens*—1, W. W. Ruthidge, Kendal. 2, J. White. 3, J. Martin. *hc*, Rev. G. Hasler, York; W. Arkwright, Chesterfield; W. Copple, Prescot, Lancashire; G. Whitcombe, Puffley, Gloncestershire. *c*, J. Copple, Prescot, Lancashire; J. White.

Dorkings (Coloured except Silver-Grey).—*Cockerel.*—1 and 3, N. Russell. 2, J. White. *hc*, W. Arkwright (2); N. Russell (2); Rev. J. G. A. Baker (2); J. Martin. *c*, N. Russell, Brynegwyn, Oswestry; Miss Davies, Chester; J. Robinson, Garstang; J. Copple; W. Copple; W. W. Ruthidge. *Pullets*—1 and 2, W. Arkwright. 3, Rev. J. G. A. Baker. *hc*, Miss Davies (4); A. Darby, Bridgnorth; J. White; J. Copple; W. W. Ruthidge.

Dorkings (Silver-Grey).—*Cock.*—1. T. Raines, Stirling. 2, J. L. Lowndes, Aylesbury. 3, R. D. Holt, Windermere. *hc*, T. L. Jackson. *Hens* or *Pullets.*—1, R. D. Holt. 2, T. Raines. 3, W. W. Ruthidge. *hc*, J. C. Cooper, Limerick; R. D. Holt.

Dorkings.—*Rose-combed.*—1, D. Parsons, Preston. 2, Miss Fairhurst, Ormskirk. 3, J. Robinson. *hc*, Hon. D. H. Finch, Leamington Spa; H. Frankland, Accrington.

SPANISH.—*Cock* —1, R. Teebay, Preston. 2, Burch & Boulter, Sheffield. *hc*, J. Mansell, Longton. *Hens.*—1, H. Teebay. 2, Burch & Boulter. 3, Boulton and Glidden, Bristol. *hc*, H. Beldon, Bingley, Yorkshire; Mrs. Allsopp, Worcester.

SPANISH.—*Cockerel*—1, Mrs. Allsopp. 2, R. Teebay. 3, H. Beldon. *hc*, Hon. Miss D. Pennant, Penrhyn Castle, Bangor; W. R. Bull, Newport Pagnell. Bucks (2) *c*, R. Teebay; J. Mansell; Hon. Miss D. Pennant; W. R. Bull. *Pullets.*—1, Hon. Miss D. Pennant. 2, R. Teebay. 3, Boulton & Glidden. *hc*, T. F. Wood, Chesterfield.

COCHIN-CHINA (Cinnamon and Buff).—*Cock.*—1, W. A. Taylor, Manchester. 2, H. Lacy, Hebden Bridge. 3, T. Stretch, Ormskirk. *hc*, H. Lloyd, jun., Birmingham (2); W. A. Taylor; H. Yardley; J. Sichel, Timperley. *c*, T. Bracegirdle, Sale, Cheshire. *Hens.*—1, H. Lacy. 2 and 3, W. A. Taylor. *hc*, H. Lloyd, jun. (2); H. Lacy (2); A. Bamford. *Pullets.*—1, W. A. Taylor. 2, Mrs. Allsopp. 3, J. Sichel. *hc*, W. Sandy, Radcliffe-on-Trent, Notts; T. Stretch; W. A. Darnell, Southwell, Notts. *c*, T. Bracegirdle.

COCHIN-CHINA (Brown and Partridge feathered).—*Cock.*—1, T. Stretch. 2, Mrs. Allsopp. 3, J. K. Fowler, Aylesbury. *c*, E. Tudman, Whitchurch, Salop; J. A. Taylor, Manchester; R. White, Shirbrook, Sheffield. *Hens.*—1, J. A. Taylor. 2, C. W. Brierley, Middleton. *hc*, E. Tudman (2); S. Burn, Wigan; Mrs. Helena. *Pullets.*—1, W. A. Taylor. 2, T. Stretch. 3, E. Tudman. *hc*, J. K. Fowler.

COCHIN-CHINA (White).—*Cock.*—1 and 2, J. Sichel. *c*, R. S. S. Woodgate, Tunbridge Wells; Rev. H. Lucas, Stamford; J. Mashiter, Ulverstone. *Hens or Pullets.*—1, J. Sichel. 2, J. Mashiter. *hc*, R. S. S. Woodgate; E. Pearon, Whitehaven; Rev. H. Lucas (2).

BRAHMA-POOTRA (Dark).—*Cock.*—1, H. Lacy. 2 and Extra 4, T. F. Ansdell, St. Helens, Lancashire. 3, W. A. Taylor. *vhc*, J. S. Tainton, Gloucester. *hc*, W. Arkwright; Mrs. Bailey, Longton, Staffordshire (2); S. Burn, Whitby; J. Walker, Staffordshire; M. Hargreaves, Manchester; Hon. Miss D. Pennant. *Hens or Pullets.*—1, H. Lacy. 2, E. Pritchard, Wolverhampton. 3, W. Arkwright. Extra 5, T. F. Ansdell. *hc*, T. Stretch; J. Mashiter; R. H. Wood, Uttoxeter; J. Watts, Birmingham; Hon. Miss D. Pennant; E. Alder, Derby; W. Whittaker, Belper (3); H. Lacy; J. Sichel. *c*, E. Leech, Rochdale.

BRAHMA-POOTRA (Light).—*Cock.*—1, W. Storer, Brewood, Staffordshire. 2 and 3, H. Lees. *hc*, W. Hartley, Halifax; T. Bickford. *c*, Capt. Downman, Kingstown. *Hens or Pullets.*—1, J. R. Rodbard, Bristol. 2, J. Pares, Guildford. 3 and *hc*, M. Leno.

POLISH (Any variety).—*Cock.*—1, G. C. Adkins, Birmingham. 2, H. Beldon. 3, J. Seddon, Newton-le-Willows. *hc*, W. Silvester, Bethnal Green; G. C. Adkins; W. Harvey; W. Fearnley, Newton-le-Willows. *Hens or Pullets.*—1, G. C. Adkins. 2, H. Beldon. 3, W. Harvey. *c*, G. Speedy.

CREVE-CŒUR.—1, J. Sichel. 2, W. Blinkhorn, St. Helens. 3, R. B. Wood. *hc*, J. Cross, Bingley, Lincolnshire; C. H. Smith, W. Blinkhorn; J. K. Fowler. *c*, W. Dring, Faversham, Kent.

HOUDANS.—1 and 3, R. B. Wood. 2, W. O. Quibell, Newark. *hc*, Mrs. J. Cross; W. Dring; Mrs. Wilkinson, Manchester (2); J. Sichel. *c*, J. K. Fowler; D. Lane, Hardwick, Gloucester.

GAME (Black-breasted Reds).—*Cock.*—1, J. Forsyth, Wolverhampton. 2, C. Chaloner, Chesterfield. 3, G. Bagnall, Draycott, Staffordshire. *hc*, Hon. Mrs. Colvile; Burton-on-Trent; Bagnell (2). *c*, J. Bentley, Halifax; R. H. Wood, Uttoxeter; J. Watts, Birmingham; Hon. Miss D. Pennant; E. Alder, Derby; W. Whittaker, Belper (3); H. Lacy; J. Sichel. *c*, E. Leech, Rochdale.

BRAHMA-POOTRA (Light).—*Cock.*—1, W. Storer, Brewood, Staffordshire. 2 and 3, H. Lees. *hc*, W. Hartley, Halifax; T. Bickford. *c*, Capt. Downman, Kingstown. *Hens or Pullets.*—1, J. R. Rodbard, Bristol. 2, J. Pares, Guildford. 3 and *hc*, M. Leno.

POLISH (Any variety).—*Cock.*—1, G. C. Adkins, Birmingham. 2, H. Beldon. 3, J. Seddon, Newton-le-Willows. *hc*, W. Silvester, Bethnal Green; G. C. Adkins; W. Harvey; W. Fearnley, Newton-le-Willows. *Hens or Pullets.*—1, G. C. Adkins. 2, H. Beldon. 3, W. Harvey. *c*, G. Speedy.

CREVE-CŒUR.—1, J. Sichel. 2, W. Blinkhorn, St. Helens. 3, R. B. Wood. *hc*, J. Cross, Bingley, Lincolnshire; C. H. Smith, W. Blinkhorn; J. K. Fowler. *c*, W. Dring, Faversham, Kent.

HOUDANS.—1 and 3, R. B. Wood. 2, W. O. Quibell, Newark. *hc*, Mrs. J. Cross; W. Dring; Mrs. Wilkinson, Manchester (2); J. Sichel. *c*, J. K. Fowler; D. Lane, Hardwick, Gloucester.

GAME (Black-breasted Reds).—*Cock.*—1, J. Forsyth, Wolverhampton. 2, C. Chaloner, Chesterfield. 3, G. Bagnell, Draycott, Staffordshire. *hc*, Hon. Mrs. Colvile; Burton-on-Trent; Bagnell (2). *c*, J. Bentley, Halifax; R. H. Wood, Uttoxeter; J. Watts, Birmingham; Hon. Miss D. Pennant; E. Alder, Derby; W. Whittaker, Belper (3); H. Lacy; J. Sichel. *c*, E. Leech, Rochdale.

BRAHMA-POOTRA (Dark).—*Cock.*—1, H. Lacy. 2 and Extra 4, T. F. Ansdell, St. Helens, Lancashire. 3, W. A. Taylor. *vhc*, J. S. Tainton, Gloucester. *hc*, W. Arkwright; Mrs. Bailey, Longton, Staffordshire (2); S. Burn, Whitby; J. Walker, Staffordshire; M. Hargreaves, Manchester; Hon. Miss D. Pennant. *Hens or Pullets.*—1, H. Lacy. 2, E. Pritchard, Wolverhampton. 3, W. Arkwright. Extra 5, T. F. Ansdell. *hc*, T. Stretch; J. Mashiter; R. H. Wood, Uttoxeter; J. Watts, Birmingham; Hon. Miss D. Pennant; E. Alder, Derby; W. Whittaker, Belper (3); H. Lacy; J. Sichel. *c*, E. Leech, Rochdale.

COCHIN-CHINA (White).—*Cock.*—1 and 2, J. Sichel. *c*, R. S. S. Woodgate, Tunbridge Wells; Rev. H. Lucas, Stamford; J. Mashiter, Ulverstone. *Hens or Pullets.*—1, J. Sichel. 2, J. Mashiter. *hc*, R. S. S. Woodgate; E. Pearon, Whitehaven; Rev. H. Lucas (2).

BRAHMA-POOTRA (Dark).—*Cock.*—1, H. Lacy. 2 and Extra 4, T. F. Ansdell, St. Helens, Lancashire. 3, W. A. Taylor. *vhc*, J. S. Tainton, Gloucester. *hc*, W. Arkwright; Mrs. Bailey, Longton, Staffordshire (2); S. Burn, Whitby; J. Walker, Staffordshire; M. Hargreaves, Manchester; Hon. Miss D. Pennant. *Hens or Pullets.*—1, H. Lacy. 2, E. Pritchard, Wolverhampton. 3, W. Arkwright. Extra 5, T. F. Ansdell. *hc*, T. Stretch; J. Mashiter

POUTERS (Blue).—*Cocks.*—1, G. Ure. 2, J. Wallace. 3, T. Duncan, Dalkeith. *he*, M. Stuart, Glasgow; W. Rutherford. *c*, D. Stewart, Perth; E. Horner, Leeds. *Hens.*—1, E. Horner. 2 and 3, J. Mitchell, Glasgow. *he*, G. Ure. *c*, G. Ure; J. Porteous, Edinburgh; M. Skinner.

POUTERS (Red).—*Cocks.*—1, J. Montgomery, Belfast. 2, R. Fulton. 3, E. Horner. *c*, J. Huie. *Hens.*—1, M. Stuart. 2, J. Wallace. 3, J. Grant. *he*, R. Fulton. *c*, G. Ure.

POUTERS (Yellow).—*Cocks.*—1, G. Ure. 2, E. Horner. 3, J. Huie. *c*, H. Mitchell, Edinburgh. *Hens.*—1, R. Fulton. 2 and *he*, J. Wallace. 3, Capt. C. Thomson, Broughty Ferry.

CARRIERS (Black).—*Cocks.*—1, E. Horner. 2 and *c*, H. Heritage, London. 3, G. C. Holt, Lawton. *Hens.*—1, T. Colley, Sheffield. 2, H. Heritage. 3, M. Stuart. *he*, H. Heritage; E. Horner.

CARRIERS (Dun).—*Cocks.*—1, G. C. Holt. 2, W. Massey, Spalding. 3, H. Heritage. *Hens.*—1, W. Massey. 2, G. C. Holt. 3, H. Heritage. *c*, G. C. Holt; E. Horner.

TUMBLERS (Almond Short-faced).—1, J. Ford, London. 2, W. R. & H. O. Blenkinsop, Newcastle-on-Tyne. 3, R. Fulton.

BARBS.—1, J. Wallace. 2, W. Massey. 3, W. R. & H. O. Blenkinsop.

FANTAILS.—1, J. Sharp, Johnstone. 2, G Ure. 3, J. Huie.

TRUMPETERS.—1 and 2, T. Rule, Gilesgate, Durham. 3, E. Horner. *he*, J. Wallace; J. Bruce, Dunfermline.

OLD BIRDS.

POUTERS (Black).—*Cocks.*—1 and Extra Gold Medal, J. Mitchell 2, 3, *whc*, and *hc*, G. Ure. *Hens.*—1, J. Montgomery. 2, J. Huie. 3, R. Fulton. *he*, E. Horner.

POUTERS (White).—*Cocks.*—1, J. Wallace. 2, M. Skinner. 3, J. Montgomery. *he*, J. Wallace: M. Sanderson, Edinburgh. *Hens.*—1, J. Montgomery. 2, E. Horner. 3, J. White. *he*, W. Moon, Edinburgh; J. Huie (2).

POUTERS (Blue).—*Cocks.*—1, J. Wallace. 2, M. Stuart. 3, J. Morrison, Edinburgh. *he*, J. White; G. Ure; W. Rutherford; J. Macaulay. *c*, D. Stewart. *Hens.*—1 and Extra Gold Medal, R. Fulton. 2, J. Montgomery. 3, G. Ure. *c*, M. Skinner; J. Huie.

POUTERS (Red).—*Cocks.*—1 and 2, R. Fulton. 3, J. Montgomery. *he*, A. Wright, Meathgaside. *Hens.*—1, J. Millar. 2, J. Montgomery. 3, M. Sanderson. *hc*, A. Wright.

POUTERS (Yellow).—*Cocks.*—1, R. Fulton. 2 and 3, G. Ure. *Hens.*—1, R. Fulton. 2, A. Wright. 3, G. Ure.

POUTERS (Any other colour).—*Cocks.*—1, J. Lohoar, Larkhall. 2, J. Morrison. 3, J. Sproull, Glasgow. *c*, J. Mitchell. *Hens.*—1, A. Wintour, Edinburgh. 2, J. Millar. 3, J. Huie. *hc*, J. Bruce.

CARRIERS (Black).—*Cocks.*—1 and Extra Gold Medal and 2, R. Fulton. 3, Miss A. Anderson, Trinity. *hc*, E. Horner (2). *Hens.*—1 and Extra Gold Medal, R. Fulton. 2, G. White, Paisley. 3, E. Horner.

CARRIERS (Dun).—*Cocks.*—1, W. Massey. 2 and 3, R. Fulton. *Hens.*—1, R. Fulton. 2, T. Colley. 3, J. R. Rennards, Helensburgh.

SHORT-FACED (Almonds).—1 and 3, J. Ford. 2 and *c*, R. Fulton. *hc*, J. Wallace.

SHORT-FACED (Any other colour).—1, J. Ford. 2, E. Horner. 3, W. Lumb.

BARBS (Black).—1 and 2, R. Fulton. 3, J. Wallace.

BARBS (Any other colour).—1 and 3, R. Fulton. 2, J. Montgomery.

FANTAILS.—1, J. Sharp. 2, G. Ure. 3, A. Lockhart, Kirkcaldy.

JACOBINS.—1, J. Lohoar. 2 and 3, R. Fulton. *hc*, T. Rule; R. Fulton. *c*, J. R. Rennards.

TRUMPETERS.—1 and 2, J. Montgomery. 3, E. Horner. *hc*, T. Rule; J. Wallace.

OWLS.—1 and 2, W. Goddard, Stanhope Street, London. 3, W. Lumb.

TURBITS.—1, G. Orr, Beith. 2, Miss M. Anderson. 3, E. Horner.

NUNS.—1, T. Imrie, Bontree Park, Ayr. 2, W. Croft, Ripley. 3, R. B. Heggie, Kirkcaldy.

MAGPIES.—1, W. Brydone, Dunse. 2 and 3, E. Horner.

TUMBLERS (Any variety not Short-faced).—1, J. Sharp. 2, D. M'Naught, Kilmaurs (Beards). 3, Capt. C. Thomson.

ANY OTHER VARIETY.—1, T. Imrie (Swiss). 2, W. Goddard (Ice). 3, E. Horner (Swallows).

JUDGES.—Mr. Joseph Frame, and Mr. E. L. Corker.

BIRMINGHAM COLUMBARIAN SOCIETY'S SHOW.

(From a Correspondent.)

THIS Society's seventh annual Exhibition was held on December 28th last at the Athenæum Rooms, Temple Street, and was a decided improvement on last year's Show, there being 332 pens, as compared with 217. The quality of the birds was good, for not more than one or two pens could be pointed out as inferior; the condition in which the owners sent their specimens was also good, every bird being in perfect feather. The Show was divided into two sections—birds bred in 1871, and old birds.

BIRDS OF 1871.

Carriers (Black) were a good and strong class. First came a very good bird, so forward that many breeders declared he was an adult: such was not the case. This bird obtained the third prize at the late Palace Show. The second prizes went to good specimens that promise well for the future. This class numbered nineteen entries. We may also add that the Birmingham cup bird only received a high commendation.

Carriers (Dun).—First was a grand bird, good in every point, and promising well. This bird will most probably always stand in the front rank; the pride of place in all the young Carriers must be accorded to this bird. Second came a very good hen; third a nice stylish bird, strong in bill, good in eye, rather down in face.

Carriers (Any other colour).—First a good Blue; the second and third Blues promise well.

Pouters.—First and second came very stylish Whites, of good length of feather and leg, narrow in girth, and shown in splendid condition.

Almonds.—Fine birds, possessing every essential property for an Almond, were first and second.

Any other Short-faced.—First came a Red Whole-feather hen, perfect in head, eye, and bill, of grand carriage, and of a deep sound colour. This bird also obtained the cup for the best bird in this and the foregoing classes; she well deserved her reward. Second came a fine Yellow, and the same exhibitor was also highly commended for a Red Mottle cock, sound in colour and feather, and with only half a dozen white feathers on his butts. The third prize went to a good Kite, which looked as though he had come from the same loft as the other winners in this class.

Jacobins.—In this class the first and second prizes went to Red, and the third and a high commendation to Yellow, all of which were good birds in every point. Mr. Waitt likewise obtained the silver cup for the best bird in the young classes of Jacobins, Turbits, Barbs, Nuns, and Owls.

Turbits.—The first-prize bird was Silver, the second Blue; both were snake-headed and good; the third prize went to a deep-coloured Red, but shell-capped.

Nuns.—All the prize birds were Black. A very good class.

Owls.—All the prize birds were Blues. This was a good class, in fact the best young class we remember having seen for many years.

Dragoons (Blue).—We rather thought the third-prize bird should have been placed first, and the first-prize bird third. All were good, and of a deep sound colour.

Dragoons (Silver).—This was a good and strong class, numbering eleven pens.

Dragoons (Any other colour).—All three prize birds were Yellows, of a good sound colour. Several good Whites were also shown. These classes were judged by the Society's standard, which, by-the-by, is not "as thin as a bodkin."

Antwerps (Dun).—First was a good specimen, fine in head, bill, and style, though rather deficient in colour. The second and third-prize birds were promising, and good in colour. The first-prize bird also took the cup, as the best young bird in the Dragoon, Antwerp, and Any other variety classes.

Antwerps (Blue).—A good class.

Antwerps (Blue-chequer).—This was a strong class, all the specimens were good in head and beautifully marked.

Antwerps (Red-chequer).—The first-prize bird was very fine in eye, head, and colour—in fact perfection. This bird was in the cup pair at the last Bingley Hall Show.

Swallows.—The first and second prizes went to Blues.

BIRDS OF ANY AGE.

Carrier Cocks (Black).—First came a bird good in every point. It also obtained the cup as the best single old bird in the Show. Good specimens—in fact, birds that are fit to win at any show, were second and third.

Carrier Cocks (Dun).—The first and second prizes went to birds good in bill, eye, condition, and carriage.

Carrier Cocks (Any other colour).—First a good Blue, very stylish—in fact, the best Blue seen for some time. Second a very nice bird. A promising Silver was highly commended.

Carrier Hens (Black).—First a hen in good condition. The second-prize bird in this class was by far the best hen, and should have obtained the first place. A good hen, rather red in the lash, was highly commended. This was a good class.

Carrier Hens (Dun).—First a grand hen, good in all points, hough in bad condition. Second a good hen, of sound colour.

Carrier Hens (Any other colour).—This was not so good a class as we generally see at this Show.

Pouter Cocks.—The first prize went to a very showy White, good in length of feather and limb. Second came a good Red. Good Whites, very showy, and narrow in girth, were third and highly commended.

Pouter Hens.—The first and second-prize birds were in splendid condition, showy, of great length, and narrow in girth. All the three winners were Whites. These classes exhibited a great improvement on the previous year's Show.

Almond.—The cock bird in the first-prize pair had a perfect head and bill, good eye, colour, and carriage, and well broken; in fact, he may be considered perfection. The hen was also very fine, possessing a real Almond ground and well broken, a good head and carriage. This pair obtained for their owner the cup for the best pair of old birds in the Show.

Any Variety Short-faced.—Red and Yellow Whole-feathers, Red and Yellow Agates, and Kites carried off the honours. This we think was the best class in the Show. Every bird was perfection, in splendid condition, not a feather soiled. It is doubtful if any other fancier could produce such a lot of birds as the exhibitor of these.

Barbs.—The first prize went to a pair of Blacks that will hold their own at any show; the second also to a pair of Blacks.

Owls.—A very good pair of Silvers possessing good heads and well throated were first, Blues second, good Blacks third. This was a very good class.

Jacobins.—Blacks, Reds, and Yellows stood in the prize list in the order named. They were all good. The Blacks well deserved their place; they were a perfect pair, well matched, good in hood, frill, and mane, not a white feather to be seen below the mandible, and perfectly black to the thighs and vent.

Nuns.—This was a good class, all Blacks. The scissors had not been so freely used as is generally the case with this variety.

Trumpeters.—A good pair of Black Mottles were first. Second came a pair far too gay to be called Mottles. Both these pens of birds are good in hood, rose, and muff.

Tumblers (Long-muffed).—A good pair of Red Rosewings were

first. Three pairs of good clear Blues were respectively second, third, and highly commended. This is a colour seldom seen. Blues are very pretty when they are as good as these.

Tumblers (Clean-legged).—The first prize went to a pair of Red Mottles. Pleasant-faced Yellow and Black Baldheads were second and third. A pair of Self-coloured Yellows were highly commended.

Dragoons (Blue).—A good and sound-coloured pair of well-matched perfect birds were first. Both second and third-prize pens consisted of good birds. In a highly-commended pair the hen was good, but the cock was far too coarse for its mate.

Dragoons (Silver).—This was a good class, and numbered six pens.

Dragoons (Yellow or Red).—Yellows first; good for head and bill, though bad in colour, being slaty in back, tail, and thighs. Good Reds were second; Yellows third and highly commended. We preferred the third to the first and second-prize pairs.

Dragoons (Any other colour).—The first prize went to a good pair, the hen perfection. Most of the other pairs in this class were not up to the mark.

Antwerps (Dun).—This was a good class. Good birds fully up to the standard were first, second, and highly commended. A very good pair came third.

Antwerps (Blue).—First, the Blues that were first at the late Bingley Hall Show. This was a good class.

Antwerps (Blue-chequered). — The prizes went to good birds splendidly marked. A highly commended pair were very little inferior to it.

Antwerps (Red-chequered).—This was a good and strong class. The Antwerps as a whole were good, and such as only can be seen at Birmingham.

Any other Variety (Pairs).—Brunettes, Turbiteens, and Black Swallows were respectively first, second, and highly commended. Ice were third. Several good pairs of Satinettes, Turkish Rollers, and other new varieties were shown, and included many varieties that have been imported from the East.

Any other Variety (Single bird).—Blondinettes, Satinettes, and Brunettes took the prizes. This was a very strong and pretty class.

Antwerps (Cocks).—First was the standard cock, which well deserved his position; the second was a Dun cock very little inferior; third a good Blue-chequer. A good Dun was highly commended. This was a good and strong class of fifteen pens. The Judges remarked that twice the number of prizes could easily have been awarded.

The attendance was not up to the average. This was to be accounted for by the weather, as it rained hard all day. Through illness in his family Mr. Easten, of Hull, was not able to send any birds, although he had entered twenty pens. We never saw any show better carried out, and are pleased to find that the Society is gaining ground, having now upwards of sixty members. The whole of the 323 entries were contributed by twenty-six exhibitors. Too much praise cannot be acceded to the President, Mr. Allsop, to the Hon. Sec., Mr. Ludlow, and to the Committee for the assiduous and courteous manner in which they worked.

Mr. Allsop, Mr. Child, and Mr. Careless were the Judges. The former gentleman refrained from judging in the Dragoon classes, as he was an exhibitor, and entirely withdrew his birds from competition for the cup in the young Dragoon, Antwerp, and Variety classes.

YOUNG BIRDS.

CARRIERS.—*Black.*—1, H. Hallam, Lozells, Birmingham. 2, Equal 2, and *hc*, G. Gordin, Birmingham. 3, J. A. Cooper, Walsall. Equal 3, G. Hodgkinson, Erdington. *Dun.*—1, G. Gordin. 2, H. FIVE Silver Cups, as Special Prizes, were given by this Society.

DRAGOON PIGEONS.

I AM glad to see Mr. Frank Graham's remarks respecting this breed, as there seems to be a great difference of opinion as to the proper standard of a Dragoon. In my experience of fifteen years as a breeder of this class of Pigeon, I have found some difficulty in producing the birds stout in the bill, a property which represents the only true-bred Dragoon, provided always the bird is perfect in head, carriage, and markings. I have bred Dragoons of almost every colour except Black, which I maintain does not exist in this breed. The bars of a Silver Dun Dragoon cannot be too narrow, and must be raven-black. These markings are a very great point of excellence. Blues also require narrow jet-black bars. I have for years bred spindle-beaked birds which never obtained me a prize in a show pen except once, and had I been Judge they would not have been placed. Fanciers of the spindle-beaked Dragoon are fast dying out, and many Judges are changing in favour of stout-beaked birds. Dragoons should be almost free from wattle, and in size nearly as large as a Carrier.—JOHN G. DUNN, *Newcastle-upon-Tyne.*

WINTERING BEES.

I NOW resume my remarks on the wintering of bees, referred to in last number. This, as I have already said, has always been a fertile theme of discussion among apiarians, and various have been the modes suggested as the best.

Some, like old Bonner, the celebrated Scottish apiarian, plastered the skirts of the hive all round the board with lime, covered it over with a large quantity of pob-tow or straw, and placed a *divot*, or turf, upon the top, to hold it close down and keep the bees dry and warm. The only apertures for air were two small holes cut in a piece of wood which formed the entrance, and these were so small in size as scarcely to exceed a quarter of an inch each. During snowstorms even these small apertures were loosely stuffed with tow also to keep the bees prisoners. Some, again, like the Swiss apiarian, Jonas de Gelieu, who also wintered out of doors, having been equally careful, with Bonner, that the hives had ample provisions, covered them with matting, an old blanket, fern, or other similar substance, in order to preserve the bees from rain, frost, or cold; the entrances also being contracted, so as only to admit the passage of a single bee at a time, and closed up every crevice by which the external air could penetrate. To prevent internal moisture, however, Gelieu placed small caps on the top cemented all round with mortar, by means of which "the moisture ascending evaporates through the opening as by a chimney." To attain the same end, Taylor, Richardson, and others, place bell-glasses, "well covered with flannel, over the aperture on the top of the box or hive, removing it from time to time, and carefully wiping away from its interior the damp formed by condensed vapour."

Again, some apiarians, to prevent internal dampness, like Miner, the American apiarian, do not resort to top ventilation at all, but allow a free current of air to pass underneath the hive, by openings at front and rear during all the winter, and only shut these when breeding commences in spring, or when snow is on the ground, by using perforated zinc slides.

According to Mr. Langstroth, Mr. Quinby, who is said to have probably the largest apiary in the United States, winters his bees with great success within-doors, in a special repository fitted up for the occasion; and to get rid of the damp "he inverts the common hives and removes the board that covers the frame."

The Rev. Mr. Scholtz, of Lower Silesia, a German apiarian of considerable celebrity, is said to winter his bees in what are called *clamps*. The hives are piled in a pyramidal form, and

arranged in tiers in a circular pit bedded with straw. All is covered over with the same material, and completely boarded and protected from the influences of the weather by layers of earth surrounding all. Ample provision is made by flannels and other means for the circulation of air, and prevention of damp, by upward ventilation through the apex of the pyramid, &c. In this clamp they are shut up from November to April, and "pass the winter (says Mr. Scholtz) uninjured from damp and moisture, and with less consumption of stores."

The celebrated Dzierzon usually winters some of his weaker colonies in a dry cellar, and "they always do well." "Universal experience (writes Dzierzon) teaches that the more effectually bees are protected from disturbance, and from the variations of temperature, the better will they pass the winter, the less will they consume of their stores, and the more vigorous and nnmerous will they be in the spring."

Notwithstanding such testimonies, however, to "in-door wintering" and to burying in clamps, I am not inclined to think that there is any necessity for apiarians in this country having recourse to either of these practices. They are attended with an amount of trouble and constant supervision which contrast unfavourably with the simpler methods adopted in our own land; and De Gelieu, who has tested the different modes of "out-door and in-door wintering" in his country, most decidedly prefers the former. "The following winter (he writes), I left out the one half of my hives, and moved the other half into a cold room, according to my usual custom, when all the pains I bestowed upon them did not altogether keep them alive, nor preserve them from damp and infection. In vain I swept and cleaned the boards, or placed them on dry hay to absorb the moisture; in vain I gave them capes or joinings. With all my care there was not one of them free of diseases and infection. The winter was long and severe; and they could not be returned to the air before the last week in March, by which time they were feeble and languid, and far less prosperous than those that had passed the winter out of doors. From that time I have never taken one into the house."

I am not inclined, therefore, to recommend either of the methods adopted by American or German apiarians of wintering our bees, either in cold, dry, dark cellars, or in clamps, *alias* burying pits. Far less should I be disposed to approve of the new mode of wintering bees by the American apiarian Mr. Hosmer, brought before our notice in the Journal of 14th December, by your esteemed correspondent, "B. & W." In cases of necessity we might, with Dzierzon, try some of our weaker colonies within-doors, or such as are domiciled in unicombs, adopting a constant supervision over them, but to purposely divide our strong hives in autumn for the sake of a questionable economy in the mere consumption of a few pounds of honey, is, in my opinion, the very reverse of good management. "Experience, in this matter, is the best schoolmaster," for we all know that a weak hive in autumn is, as a rule, a weak hive in spring. On the principle, therefore, that "union is strength," in the case of the bee as of man, and believing, with Bonner, that "one (really) good hive is worth four bad ones," I cannot approve of the breaking-up or division of strong families in autumn.

Although I perfectly agree with Mr. Hosmer in the desirability of encouraging late breeding in autumn, with the view of securing a preponderance of the youthful element in every stock hive, having directed the attention of apiarians to this subject some years ago in the Journal, yet I should not, like "B. & W.," desire to get rid of their elder associates. Even upon the assumed hypothesis that the old bees, "which have consumed honey all the winter, die after their first flight in spring," I would not wish to discard them if I could, for I reckon their presence of the utmost value to the colony during the rigour of winter, as well as the commencement of breeding in spring. But is it a fact that all the old bees die during the first flight in spring, as Hosmer supposes? Certainly not. Pray what bees are these that are called "old bees?" Are they what your experienced correspondent "B. & W.," inadvertently perhaps, terms "summer-bred bees," and which he, too, I am sorry to see, thinks it desirable to get rid of before wintering? I venture to say there are, as a rule, few or no "summer-bred" bees in any of our hives in winter. All have perished, and our stocks are almost, if not entirely, peopled by autumn-reared bees. Such being the case, I think that Hosmer's theory is erroneous in principle and entirely delusive —independently, too, of the error of holding the older bees in a hive as worthless, the practice of weakening his strong stocks in autumn by division, for the assumed advantage of a few pounds saved in stores, is one which will never be followed by experienced apiarians, as it is alike irreconcileable with the known winter habits of the bee, as it is opposed to all sound and enlightened management.—J. Lowe.

ARE ARTIFICIAL QUEENS INFERIOR TO NATURAL QUEENS?

Mr. J. M. Price, writing in the American "Bee Journal," asserts that he has proved, beyond doubt, that queens raised artificially are worthless in comparison with those raised naturally. From my own experience I am led to differ from him most decidedly. Out of twenty-five stocks, the largest number of colonies I ever possessed at one time, I had not a single queen that was not either artificially raised in a small nucleus box, or was not the descendant of one who was so raised, but I could never discover that my queens were deficient in breeding powers, or, barring accidents, in longevity. In fact, the fecundity of some of these was frequently a subject of surprise and remark. One queen, in particular, seems to stand pre-eminent in these respects.

Soon after the first introduction of Ligurian queens into this country, my own double venture having proved unpropitious, my friend, the late Mr. Woodbury, gave me a royal cell, which he cut out of a small nucleus box, from brood of his best yellow queen. This cell I inserted in a brood-comb in a nucleus box with a few adult bees. In a few days she was hatched out, and I was struck with her size and beautiful colour. Soon after she had commenced breeding I transferred them into an eight-frame Langstroth box, and gave the bees another sealed brood-comb. The stock was not particularly strong at the close of the autumn, and barely managed to hold its own through the winter; but by the end of April it had become so populous as to present the appearance of being ready even then to send off a swarm. A large super was given to the bees, into which they at once ascended, and were so crowded as to make it seem almost impossible for them to work at comb-building. In about three weeks from that time, considerable progress having been made in that respect, and the bees again crowding outside the entrance, a second super was slipped in between the first and the honey-board of the stock box, which also became at once crammed with bees. Early in July I removed the doubled super, containing 54 lbs. of honeycomb.

The following year this stock also distinguished itself in spring and early summer by the possession of a teeming population, and gave a splendid glass box super of 75 lbs. weight. The next season seemed equally propitious; a super of 50 lbs. was taken, and an immense swarm thrown off, which also the same summer gave me a super of 26 lbs. weight. The following spring I examined the queen which had come off with this swarm, and was convinced in my own mind, from her peculiar markings and appearance, that she was the same queen which had been raised in the nucleus box. That season this swarm became excessively crowded, and I put on a larger super than I had ever before used, and it contained when full the large quantity of 86 lbs. of the finest possible honeycomb.

The following spring the old queen showed symptoms of having become almost worn-out, and was, I believe, soon afterwards superseded by the bees, as I discovered a queen of a very different character at my next inspection of the interior. At the time of the old queen's death she must have been at least four years and a half of age.

I mention but this one instance out of many which have come before my notice, but it is quite sufficient, in my mind, to establish the truth of the assertion, that artificial queens may and do prove equal in every respect to the best of those raised by the bees for the purposes of natural swarming.—S. Bevan Fox.

Shading in Winter.—Mr. Taylor says:—"Where the hives stand singly, I have always seen the advantages of fixing before each a wooden screen, nailed to a post sunk in the ground, and large enough to throw the whole front into shade. This does not interfere with the coming-forth of the bees at a proper temperature, and it supersedes the necessity of shutting them up when snow is on the ground. The screen should be fixed a foot or two in advance, and so as to intercept the sun's rays, which will be chiefly in winter towards the west side."

OUR LETTER BOX.

Golden-pencilled Hamburgh Hen (*P. C.*).—We do not say we have never seen one with a clear hackle and pencilled tail, but it is a very rare occurrence, and we should not know where to find one at any price.

Top-knot Plucked Off (*H. K.*).—It is more than likely the ointment you require would be injurious to the feathers growing in the top-knot. The best ointment you can use will be strong sulphur. The hens only eat the feathers while they are growing; after they are formed they leave them alone. There can be no objection to separate them for a time, or, if necessary, to allow them occasional runs in company, being watched all the time that the luxury may not be indulged in. It is not for any purpose necessary they should always be together.

Various (*M. H.*).—La Flèche fowls are never strong, and we believe they lack constitution. They will bear rich food very well, but they are never well if supplied with water. We allow them to drink only morning and evening. The cock you speak of has either outgrown his strength, or was not sufficiently well fed when young. If he is not essential to your yard, do not attempt to save him. He is not worth it. He will never be fit for a stock bird.

Washing a Buff Cochin (*E. C. V.*).—Wash the plumage with soft soap and water, the former in small proportion. Use a sponge, and be content to wipe the feathers gently down without moistening the under plumage, which is always clean. Wipe them afterwards with flannel, and put them in an open basket with some soft straw before a fire. They will dry clean. Be sure you wash the fowl's legs as well as the feathers. Ground oats mixed with kitchen scraps will put on weight very fast.

Brittleness of Feathers (*H. B.*).—Your Hamburgh cock is changing his hackle, and the feathers only look as if they were broken. They will come right if they are let alone. Your feeding is very bad. Indian meal once per day is enough. You may give it in the morning; give good ground oats or oatmeal midday, and whole Indian corn in the evening. The tendency of Indian meal is to cause extreme fatness, and that is not favourable for health.

Breeding Pile Game Fowls (*H.*).—You can breed Piles either from the birds you name, or from a Black Red cock and White hen. You can breed Piles from a Brown Red cock and White hen, or between a White cock and a Ginger hen. They would not be faulty, but if you have any fixed ideas as to what you want, you must remedy the failings in the produce, by mating birds possessing the properties you require with those of the first cross that comes nearest to your standard.

Legs of Pile Game Fowls (*An Old Game Breeder, &c.*).—We cannot agree with you about the colour of the legs of Pile Game. Nearly fifty years ago we had much to do with Cheshire Piles, and there were Willows among them. Many years ago we shipped a main of Piles to the West Indies, and many of them had willow legs. We are heterodox enough to believe that the colour of the legs is immaterial; that whether it be a Derby Red with white legs, or an old Red with yellow, or a modern Red with willows, we should in the pit make choice of the bird without looking at the colour of his legs. If you can find as any county, or even large district, where Game fowls prevail, and where legs of only one colour are to be found, we shall ask ourselves a question, but at present we side with the judge or judges, and think "*in re* Game fowls," it is necessary all legs in a pen should be alike, but no colour in itself is a mark of greater or less purity or excellence.

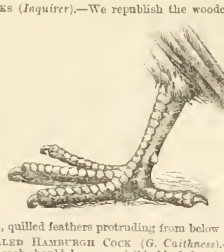
Price of Cochin Cockerel (*Devon Reefer*).—Such a bird as you describe, between gentleman and gentleman, should make £1.

Fowl's House (*G. A.*).—Your fowls have cold, stimulants such as strong ale are required. Hamburghs are more prone to roup than any others. Wash the swollen eyes with vinegar and cold water. Give Baily's pills. Get rid of the Hamburghs, they are "messing."

Pullets Picking a Cockerel's Flesh (*E. White*).—You must separate the cock from the hens till his top-knot is grown. It will then be safe from attack. In these matters cocks somewhat resemble gentlemen, they stand quiet while they are put to pain, looking for the "compensation balance" in the fact it gives the ladies pleasure. A cock or a cock Pheasant will stand still to be eaten alive by the hens. Bruce's tradition of the Abyssinians cutting a rump steak, day by day, out of the living ox, is nothing compared to a Spanish or Houdan cock standing still, the one while his head is eaten, and the other while his face is being pecked.

Selecting Stock Fowls (*Hants Housewife*).—No. 1 should have gone into the stock-pot last year. How is it you hatched no cockerel till August? Because No. 1 was too old. No. 2 is too young; 5, 6, 7, should go with an early bird of last year. Your failures of last year are your own seeking, and if you breed as you propose, you will hatch fewer eggs and have more faulty birds.

Vulture Hocks (*Inquirer*).—We republish the woodcut. Vulture hocks



are long, straight, quilled feathers protruding from below the knee.

Silver-pencilled Hamburgh Cock (*G. Caithness*).—A good Gold-pencilled Hamburgh cock should have no visible black but in the tail, and those feathers should be edged with bronze.

Plymouth Show (*J. Long*).—We hope you are correct in stating that it was "a success in every sense of the word." What you state about another party's misfortunes is not suitable for publication. (*N. Barter*).—There is no need to make further inquiries. Let us see what the present year will bring forth.

Edinburgh Poultry Show (*J. Rollinson*).—It was very careless of the Secretary not to send your prize Golden-spangled Hamburghs to Manchester as was undertaken by the Society. It was the more vexatious because you travelled to Manchester. "*An Exhibitor*," *Cambridge*, was similarly badly attended to, and at a cost of 25*s*.

Canaries (*H. G.*).—If your letter was received the query was answered; but we have too many questions daily to be able to remember each. Send your query again.

Spratt's Cat Biscuits (*Anthony*).—As you cannot obtain an answer from the factory we cannot advise you. Buy Meyrick's little book on dogs.

REMARKS.

27th.—Bright sunshine with showers in the morning, fine in the evening.

28th.—Dull, overcast with slight showers, sunshine for a short time about noon, but dull day.

29th.—Rain in the night and till 9 A.M., then a fine day and beautiful moonlight night.

30th.—Beautiful moonlight in morning and splendid sunrise, wind rather high, clouded over soon after 8 A.M., and a damp uncomfortable day. White aurora between 8 and 9 P.M.

31st.—Slight white frost in morning, fine day, bright sun but rather cold wind.

1st.—Very fine all day, wind gradually rising after 6 P.M., rather high at night.

2nd.—Dark and wet in morning, slight showers during the day. Several meteors at night, mostly radiating from near Gamma Ursæ Minoris.

The temperature continues unseasonably high, with southerly winds and continued dampness.—G. J. Symons.

COVENT GARDEN MARKET.—January 3.

As usual at the close of the year, business transactions are limited to actual wants, and have no marked features in them. It has seldom been our lot to see a better or larger supply of roots and green vegetables than has been offered during and since the Christmas week; certainly the million have been amply supplied. Potato trade is heavy with large stocks; the Dunbars and East Lothians rule highest in the market.

POULTRY MARKET.—January 3.

It is impossible to give any account of the market for Christmas, or for some days afterwards, within the limits of a market notice. Should space permit we will give an article on the subject. Very choice poultry made good price throughout the Christmas week. That of inferior quality was unsaleable, and much of it remains unsold now.

From observations taken near London during forty-three years, the average day temperature of the week is 42.1°; and its night temperature 29.6°. The greatest heat was 54°, on the 12th, 1852; and the lowest cold 3°, on the 13th, 1867. The greatest fall of rain was 0.86 inch.

PEAT SOIL.

IT is a generally received opinion that Heaths, Azaleas, and other plants with delicate hair-like roots cannot be grown without peat soil. Such a conclusion, however, is often a mistaken one, and leads not unfrequently to failure; for, acting on the impression that peat soil is indispensable, soil bearing that name is procured, and proves wholly unsuitable for the plants for which it was intended. Some, too, knowing that peat is required for growing a certain class of plants, trust the selection of them to some as ignorant of the soil as they are of the plants themselves. There is a great difference in peats—some being of great importance to the gardener, others wholly unsuitable, and, indeed, hurtful for most of the purposes of floriculture.

Whilst admitting turfy peat soil to be the best for hard-wooded plants, such as Heaths, Azaleas, and others with very delicate roots, my experience nevertheless leads me to the conclusion that it is not, as is commonly supposed, indispensable. Peat is a deposit of vegetable fibre, the consequence of a long-continued growth on the same spot, and the dark colour of the soil we term peat is given by the plants. Proof of this may be found in the fact than an Azalea or Rhododendron, planted in a light-coloured sandy loam full of fibre, will within a quarter of a century change the soil to a dark brown peat, and the sand that was formerly the colour of the loam, is then as white as the finest silver sand. Heath on our moors forms the same deposit of dark-coloured soil, and if evidence were needed that the soil was not originally what we call peat, we could produce abundant proof of it. Here on the light-coloured loam springs up the Heath amongst the turf overlying sand or stone, and so close does its growth become that the grasses give way, and the Heath spreading out forms first a clump, and eventually a peat moor, which was once a light-coloured loam interwoven with a tough thick-growing turf. It is the property of plants to effect an alteration in the colour of soils, and even to enrich them with their own decayed parts, which enable the subject to exist on the same spot—for every plant in a state of nature supplies itself with the elements of existence—and fit the soil for a higher or grosser-feeding type of vegetation. The moss on the rock forms a rooting-ground for the Fern, just as the lichen on trees forms a lodgement for the epiphytes. So whilst cultivated plants take from the fertility of the soil, those in a wild state enrich it and add to its depth by their decaying parts, being generally succeeded, and often accompanied, by a higher and deeper-growing class of vegetation.

Peat, then, is a deposit of vegetable matter, consisting of a "sharp sandy soil mixed with the dead fibrous roots of Heath, and is usually of a dark grey colour." There are, however, brown and black peats, due, I consider, to the colour of the loam prior to the growth of the plants. I think the term peat is an inappropriate one for the soil of such value to the gardener, as we give the same name to every kind of dark spongy soil, whether it be that overlying rock or dry elevated ground in a thin strata; or that on a wet clayey subsoil of considerably less elevation, thinness, and lightness; or that from ground moderately dry, but moist enough to produce sphagnum—in which case the peat is brown in colour, very spongy, and not of more than a few inches thickness—or that from low ground, where, from the decay of sphagnum or plants allied to it, a deep layer, generally wet to the roots, is formed; all these, with many others that I could name, are included in the designation of peat. Heath mould would be a better name for the soil that is used for what I consider to be the finest plants of the garden.

The heath mould or peat, generally used for delicate hair-like rooted plants, is the soil which occurs in elevated well-drained moors, exposed to the withering blasts of winter and scorching heat of summer. The soil, usually less than a foot, and often only a few inches in thickness, lies on a layer of sandstone, limestone, freestone, or grit, being so thin, and the subsoil so sterile, as to forbid profitable tillage, but yielding a thickly-woven tough turf of very fine grass and good close-growing Heath. The top soil taken off 3 or 4 inches, or as far as the deposit of vegetable matter extends, is highly friable and dark-coloured, containing a considerable proportion of fine grains of white sand, and if laid up in a stack for a few months, it will ultimately form the peat so valuable for cultural purposes. It cannot be too fibrous, provided it be full of white sand, in fact the tougher the better. Never take it off so deeply as to bring away any that is close and devoid of fibre, and avoid that which is of a soft spongy texture. It may be black, brown, or dark grey, but the main consideration is texture, though colour shows the advanced state of the decay of the vegetable matter and the thickness of the deposit. The sooner a deposit is formed the less time is there for decay, and the lighter is its colour; whilst the slower the deposit the more complete is the decay, and the greater the blackness of the soil.

Now let us compare this heath mould with a light loamy soil covered with a thickly-woven turf, and what is the difference? Is it not in the decomposing vegetable matter and the smaller quantity of clay in the peat to what there is in the loam? Mr. Johnson, in the "Science and Practice of Gardening," page 96, tells us that "Peat of the best description is constituted in 400 parts."

PEAT.		LOAM.	
Fine siliceous sand	156	Fine sand	120
Unaltered vegetable fibre	2	Decomposing vegetable matter	100
Decomposing vegetable matter	110	Silica	130
Silica (flint)	102	Alumina	18
Alumina (clay)	16	Oxide of iron	10
Oxide of iron	4	Carbonate of lime	12
Soluble, vegetable, and saline matter	4	Sulphate of lime	1
Muriate of lime	4	Soluble, vegetable, and saline matter	5
Loss	2	Loss	4
	400		400

Now let us compare this with an analysis of loam of a

light sandy nature, in a close herbage that has accumulated so as to form a thickly-woven fibry surface of turf, taken off 1 to 1½ inch thick, and laid up for three months to decompose. The difference is not very great, and the only objection that can be urged against a soil of this description is the excess of lime and iron, in which there can really be no serious drawback, as the excess of iron is probably decomposed by the lime. There is also a slight excess of clay that may be overcome by the addition of sand, and the deficiency of vegetable matter may be compensated for by adding some old cow dung or leaf soil, with a large amount of sand. This soil should be laid up a few days or weeks, according to the period of the year, less time being needed in summer than winter, and finely chopped-up for small plants, and moderately so for large ones. If used rather rough, let there be a good proportion of finer particles, so as to fill up the interstices and allow of firm potting, adding to it one-sixth of silver sand, and a twelfth part each of charcoal in lumps from the size of a pea to that of a hazel nut, and broken pots that will pass a half-inch sieve; mix this thoroughly, and what is the plant that will not grow in it? I am not prepared to say that it will suit the most delicate of plants which require heath soil, but it will grow such subjects as Azaleas and Rhododendrons much better than any peat, and is especially suited to Camellias. So-called American plants require vegetable matter and plenty of sand; indeed, most, if not all, Cape, New Holland, and American plants need decomposing vegetable matter in the proportion of one to two of sand, a small proportion of clay, and very little lime or iron. In such a soil they will thrive, and by the decomposition of organic material and their own decaying parts, will give origin to the soil we term peat.

I have been so often disappointed by peat, that I have no hesitation in giving preference to the top inch of an old common, the soil of which is stony, rocky, or sandy underneath, and the old turf at the surface very tough, sandy, and partially decomposed. I use it for the purposes of peat in the culture of pot plants, but for American plants out of doors I do not consider peat needed. For plants in beds I prefer compost formed of the first 2 or 3 inches of an old pasture, chopped-up rather roughly and enriched with leaf soil from a wood, or from where Bracken and Foxglove grow, and the whole top-dressed with cow dung and plenty of sharp sand, to make the soil light and porous. This soil will grow Rhododendrons, Azaleas, Kalmias, Andromedas, and hardy Heaths much better than the majority of peats.

It should be stated that some peats are so ferruginous as to be wholly unsuitable, and some contain iron in such quantity as to be actually poisonous to plants, and yet the soil bears a very good growth of Heath. On examination, however, it will be found that the layer of peat is very thin, the ferruginous substance being immediately under it, but none of the fibres of the Heath entering it. These ferruginous peats are also very deficient of silica, though the subsoil is frequently a compound of 150 sand, 120 silica, with as much as 50 of alumina, oxide of iron 35, water not entering but running off by the surface. If the ground has not a sharp incline, the Heath is often covered with lichen and sphagnum. Even the surface of these soils is of no use, as they are so largely impregnated with iron and so deficient of sand.

There are peats, again, that overlie limestone, and are so impregnated with it as to be wholly unsuitable, especially those on the magnesian formations. It is remarkable, however, that even those formations on which there is but a thin deposit of vegetable matter, will grow plants which need peat well if undisturbed, but this, if removed, is destructive to plants in pots or in a cultivated state.

It is also necessary to make some remarks on the kinds of sand used for mixing with loam intended to be employed instead of peat. There is the sand rock, which is a compound of lime, and when burned forms the finest silver sand. In its natural condition it is simply poisonous to plants, and when washed it renders the water milky. There are also pit sands very full of iron, and nearly useless. All sands should be washed in a very fine sieve, skimming off the top. This frees them of loam or aluminous matters, and also of what those persons who use sand for cement or lime term "blacks." These spoil the work, and if not removed will also destroy the roots of plants.

Peaty turf, such as is used for fuel, is of no value for plant-culture, being almost destitute of silica. It consists of sphagnum and allied plants, frequently forming a deposit to a great depth, but it is also often found in only a thin layer. It usually occurs in low ground and saturated with water, where the subsoil is very clayey and almost without stones. This is only useful for the growth of bog plants or for fuel.—G. Abbey.

SMALL FARMS—HOW THEY CAN BE MADE TO ANSWER.—No. 5.

By Rev. William Lea, *Vicar of St. Peter's, Droitwich, and Hon. Canon of Worcester.*

Vegetables.—I have now exhausted the usual varieties of fruits with the exception of Filberts (Strawberry cultivation comes more nearly under the category of vegetables), and notwithstanding the very tempting accounts of the profit of Filbert-growing which I have seen in print, I cannot say that I have found it successful. It is stated in a pamphlet which I have before me that Cob Filberts are readily sold at £7 for 100 lbs. weight—that is, about 1*s.* 4*d.* per lb. My experience was not so fortunate, as the crop produced the odd fourpence without the shilling, so we will dismiss them from our consideration. And the point I now wish to come to is this: When a field is planted with fruit, it will be some years before the trees fully cover the ground, or there may be parts of it left open for vegetable cultivation—what will be the most profitable vegetables to grow? I mentioned the Strawberry above; and where the ground is well suited for the growth of this fruit, and sufficiently near to a market, probably few kinds of produce will bring a more profitable return. The difficulties are, that it carries very badly, and requires to be netted over where birds are numerous. I have never made an experiment as to the market value of Strawberries, but after many years' experience as a grower I may be able to throw some light on the subject to those who may wish to begin.

First, double-dig your ground and manure it heavily; then put in your runners, being careful to select first runners—*i.e.*, those nearest to the parent plant; put them in as early as you can, and not later than the middle of August, or you will not have much of a crop the first year. Plant them in rows 12 inches apart, and 12 inches between the plants. Directly the fruit is gathered hoe up every alternate row, so as to leave for the second year rows 2 feet apart, with the plants 12 inches from each other. Directly the fruit is gathered the second year, hoe up every alternate plant in the rows, so as to leave for the third year rows 2 feet apart, and plants 2 feet from each other. Clean your beds by the end of August; in November hoe them over, and put on a good surface-dressing of manure, and at the end of May, when the plants are just going out of blossom, give them a good watering with liquid manure—this will materially increase the size of the fruit. Some prefer to let the plants run all together, so that the ground is completely covered. The advantage of this plan is that the birds do not see them so plainly; the disadvantages, that the fruit is smaller, less abundant, and in a wet season worthless.

The varieties of Strawberry to be grown must depend upon your soil. Where the British Queen will succeed it should always form a part of the plantation; but it will not grow on all soils. I have never been able to do any good with it myself. The earliest of all sorts is the Black Prince, but it is hardly a Strawberry, and would not be looked at when once Keens' Seedling has been seen; still, on account of its earliness it may be worth a trial. To succeed this I should recommend Keens' Seedling and President, which last, as far as my experience goes, is the hardiest, the longest-lived, and the most prolific of all Strawberries, and one which will carry well. Then come Sir J. Paxton, where it will grow La Constante, and of later sorts Filbert Pine, Frogmore Late Pine, and Stirling Castle; but the king of all is Dr. Hogg, unequalled in size and flavour, but I fear a short-lived variety, and of a tender constitution. These are the varieties which I have found to succeed best on a light loamy soil, and on such a soil I should say that nothing would beat the President for market purposes.

I now come to the question of vegetables; for if a field is planted with fruit (trees such as Plums, Apples, or Cherries, in rows 24 feet apart, and bushes, such as Gooseberries or Currants, between them in rows 6 feet apart) for the first six or eight years, there will be room for vegetables between the rows, and also between the bushes. What varieties can be grown to the greatest profit?

In the first place I should put Onions, Garlic, or Shallots, because they interfere less with the roots of the trees than any

other vegetable; and the last especially, if the soil is in good heart, will produce a larger profit per square yard than anything else. Carrots and Parsnips may also be grown, and the latter will hold their own, and produce large roots, even if quite overshadowed by the bushes, when nothing else will succeed. But the most profitable crop for the first few years will probably be the Potato, especially the early varieties which do not make too much haulm, such as the Ashleaf, Early May, Alma, The King, and other kidneys, which are always in demand before the later Potatoes come in, and even then seem to be preferred before them. Of the later sorts the best and the most prolific (but this again is a question of soil), are the Red Regent and the Victoria, both of which will keep perfectly sound till Potatoes come in again. But if a part of a field is left open, and not planted with trees, nothing, probably, will be more profitable than Asparagus beds, if the farm is near to a good market.

With regard to manures, there is none which can be compared with farmyard manure, more especially if the crop is to be planted among bushes and fruit trees. Some persons have a prejudice against "green" manure; but I would say, When you are planting, put on every bit of manure you can scrape together, rotten if you have it; if not, green. I have seen just as good and healthy crops of Potatoes, if not better, grown from manure full of soakage wheeled straight from the pigstye, as from the well-matured heap which had accumulated during the previous year. I say, then, there is nothing like farmyard manure. It lasts for two or three seasons in the soil, while artificial manure is exhausted in one. But among artificial manures there is a difference. I have tried experiments with many varieties, and have found nothing so efficient for Potato-growing as Peruvian guano, if it can be procured unadulterated. A little goes a long way, if dropped by hand upon the set when it is planted in the ground. And this mention of manure leads to a consideration of the sources from which it is to be derived. A fruit-farmer *must* have it, and as it is not always to be purchased, he must keep a certain amount of stock to produce it. What that stock should be we will consider in another paper.

(To be continued.)

ELECTION OF ROSES.

Mr. Radclyffe, in your last, after commending the lists of Roses on the whole, thinks there are two shy bloomers, six bad growers, and six *presque pleine*, in the thirty-six.

With regard to the *presque pleine*, I think that not only some of the very best garden Roses, but some of the very finest exhibition Roses belong to this division; and though some of them are dangerous friends, in a stand, as in a hot tent, they are apt to open too rapidly and show an eye, yet, as a rule, their constitution is better than the very double ones, many of which, like La Reine, Reine du Midi, Alpaïde de Rotalier, and others, at times utterly refuse to open, and others, again, open flat and rough, like Thyra Hammerick, Souvenir de Poiteau, Baronne Prevost, &c. What Roses can be finer than Duke of Edinburgh, Xavier Olibo, Pierre Notting, Victor Verdier in their half-expanded state? There are very few Roses that will bear, as I sometimes see done, a Judge's pencil stuck into the middle to poke in and see if there is a yellow eye, and then they are condemned, because they say, "Oh! that Rose wo'n't do, it will open directly and show a yellow eye, very likely by the time the public are admitted."

There are some of the Roses which have incurved petals, like Prince Henri de Pays Bas, Felix Genero, and Louis XIV., which keep their shape longer, but many of these Roses have quite as much a yellow eye as the *presque pleine*, only on account of the incurved petal they do not show it so much.

I am induced to write this, as I am myself a great admirer of that section on account of the beauty of the bud and half and three-parts-opened flower, as instance Général Jacqueminot and La France. In my opinion, as a general rule, they are the most useful Roses that can be grown, and I should be sorry to have them discarded as exhibition blooms on account of their tendency to show, not the cloven foot, but the yellow eye when past their best.—C. P. Peach.

Everyone will agree that Mr. Peach has rendered valuable assistance to Rose-growers by canvassing the most eminent rosarians of the day for the election of the twelve best and the thirty-six best Roses. From this election we find that we have about sixty Hybrid Perpetual Roses which may be relied upon with perfect confidence as really first-rate. Those Roses which have only had one vote are, I believe, mostly excellent, but so far scarcely sufficiently accredited. Now, I propose that this election be carried a little further, and that the same able rosarians be canvassed again for their opinions as to what other Roses, besides those already elected, are really worth growing either for the garden or for exhibition. This would enable the public to understand, once and for all, what Roses are really worthy of cultivation, and nurserymen what Roses they may with perfect confidence propagate.

To carry out this desirable object I would suggest that the Roses be divided into three classes—1, Hybrid Perpetual, Bourbon, and China Roses; 2, Noisettes and Tea-scented; 3, Summer Roses, such as Paul Verdier, Miss Ingram, Paul Ricaut, &c., first-rate, but only summer Roses. I would further suggest that the electors prefix an asterisk to those Roses which, however beautiful for the exhibition table, are unsuitable for the garden, either as too tender and weak, or too unwilling to open their blooms; also that they should prefix the letter P to those Roses which are most perpetual in their habit.—R. T.

[I think your suggestion a very good one, and shall be glad to receive lists from rosarians, which I would analyse and publish the results, leaving out the thirty-six already named, naming in addition, say, thirty-six Hybrid Perpetuals and Bourbons, add the Chinese to the Teas and Noisettes, and name twenty-four and twelve summer Roses. This would give seventy-two, in addition to the thirty-six already selected. If more than these are named it adds seriously to the trouble of compilation, and 108 Roses are a goodly number, though I have little doubt twice that number will be named to obtain the requisite seventy-two.—C. P. Peach.]

ROSES—HYBRIDE REMONTANTE.

I can find neither of these words in my French dictionary, De Porquet's. There is no such word as Hybrid in Walker's Dictionary. [There is in Johnson.] There is "Hybridous—begotten between animals of different species; produced from plants of different kinds." "Remontant" is neither French nor English. I think the term Hybrid Perpetual is quite as good as Hybrid Remontant, and more generally understood, Both the French and English terms are equally applicable to the Tea-scented Noisettes, which are mules or hybrids, and likewise Remontants. The French probably derived the word from "*remonte*—new horses bought to remount the troopers." If so, Hybrid Remounts or Remounters would be an intelligible and exact translation. The verb "*remonter*—to go up again," may probably be the origin of the term. In the English part of De Porquet's dictionary "remount" is "*remonter*." I am satisfied with Hybrid Perpetuals, but if we are not to have that I can see no better term than "Hybrid Remounters."

I agree with "D.," it is difficult to get fresh terms generally adopted. The English love to copy the French, as if they had no ideas of their own. They, moreover, love to intersperse Latin, French, and Greek words, or crackjaw derivatives, into their articles to the confusion of humble readers. This is "philosophy vainly so called," because it conveys no instruction to the illiterate.

One word about "*belle tenue*" and "*se tenant bien*." No doubt they both mean "erect habit." *Ferme pédoncule* or *pédicule droit* would set the matter at rest. The English word is pedicle and not peduncle, which is Anglo-French, and is not to be found in Walker's dictionary. I cannot find either the word peduncle or pedicle in the English part of De Porquet's dictionary, but in the French part I see both *pédoncule* and *pédicule*.—W. F. Radclyffe.

MEADOWBANK.

This, the residence of T. Dawson, Esq., is at Uddingstone. It is small in extent, but well worthy of a visit. The grounds are well laid out and kept in good order, and have also the advantage of being beautifully situated on the banks of the Clyde. In taking a hurried walk through the grounds, where the modern style of flower gardening has been adopted, I noticed amongst other minor features a rather extensive collection of herbaceous plants. These, very properly, occupied a quiet

nook by themselves, but I could not, owing to want of time, inspect this collection as I very much wished to do.

No doubt most of your readers are aware that this place owes its celebrity to the extensive and select collection of Orchids which Mr. Dawson has collected, and which is now under the care of Mr. Anderson, his able gardener. The Orchid houses are numerous, principally span-roofed, with fixed upright sashes. Ventilation is obtained from the apex of the roof, and from ventilators in the side walls, fixed in such a position that the air is warmed by passing over the hot-water pipes before it reaches the plants. In the narrow span-roofed houses, 12 feet wide and under, the internal arrangement consists of thick sandstone slabs down each side with a path in the centre.

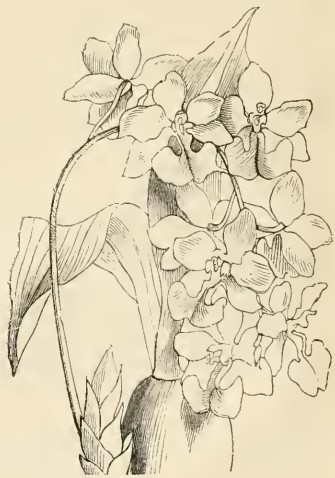
Phalænopsis amabilis.

There are several larger houses of the same description, two of which are used as show houses, one for cool-house Orchids, and the other for those requiring the temperature of the East-India house. These houses have a stage in the centre and one round the sides and ends.

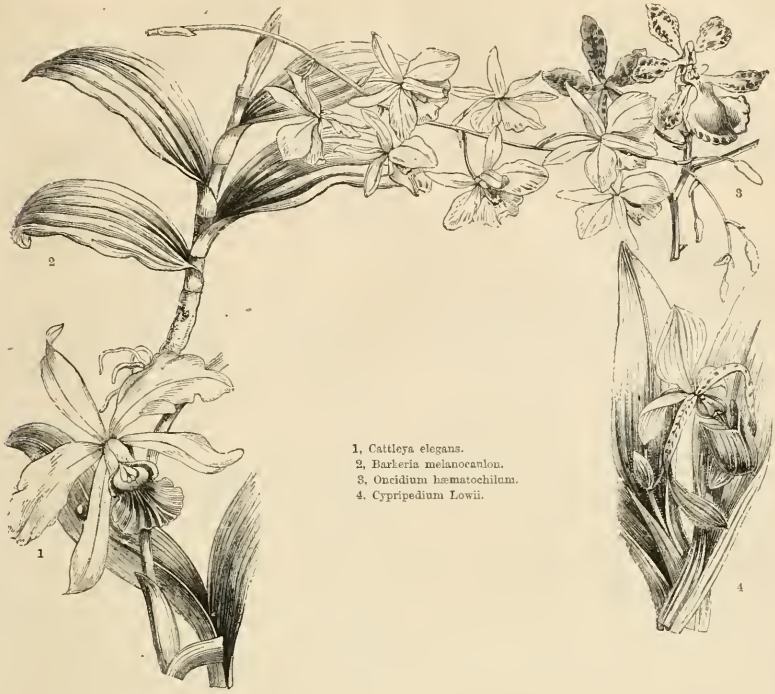
The first house I entered was 65 feet by 12 feet, in two divisions. In one compartment was a collection of Amaryllis, a class of plants which Mr. Anderson has taken in hand, and of which he also possesses many seedlings from cross-impregnated flowers. This is a class of plants not so much cultivated as they deserve to be. They cross readily with kindred species, and are easily raised from seed. The form of the flowers has been much improved by crossing with Hippeastrum pardinum, as witness the splendid flowers in the hands of the Messrs. Veitch, of Chelsea, such as A. Chelsoni, A. Leopoldi, &c.

Passing into the next division we find an East-India temperature, in which are different species of Phalænopsis, such as P. Schilleriana, of which there is a magnificent specimen. This plant, with P. amabilis and P. grandiflora, should be in all plant stoves where a night temperature of 60° can be maintained during winter. In some collections of Orchids the Phalænopsids are sometimes to be found in bad condition. I have charge of a fine specimen of P. grandiflora, which came under my care five years ago in bad health; it was removed from the compost in which it was growing at that time and the roots washed, it was then fastened to a block of wood with some fresh sphagnum round the roots. The block was placed in a pot, the space between the block and sides of the pot being filled-in with clean potsherds, and the surface covered with fresh sphagnum up to, but not over, the roots. The plant has made steady progress ever since. All the treatment it has received has consisted in giving it a little fresh sphagnum once a-year. The roots ramble over and clasp round the pot, but they are in no way disturbed. A successful exhibitor said to me the other day when I was admiring his healthy stock of Phalænopsis, "If you want to grow them well, do not disturb the roots as long as the plants are healthy. I only dip the baskets in water once a-week." At the time of my visit to Meadowbank on September 20th, P. cornu-cervi and P. rosea were in flower.

The Cattleya house also contains grand specimens of this family; indeed, what struck me most in looking over this collection of Orchids, was the size of the individual specimens and the number of flowers they produce. It is also very evident that no inferior varieties have a place. For instance, in conversing with Mr. Anderson about Cattleya Warneri, we agreed that many inferior forms of it exist in the country. The same may be said of many others. I have not yet seen a bad variety of Cattleya exoniensis, yet, fine though it is, a particular specimen I saw in flower here was surpassingly beautiful. Cattleya citrina was grown both on blocks and in pots. It does best on blocks, with the leaves hanging downwards. Odontoglossum citrosmum was thriving in the Cattleya house; it requires more heat than other Odontoglots.



Odontoglossum citrosmum



1, Cattleya elegans.
2, Barkeria melanocaulon.
3, Oncidium hæmatochilum.
4, Cypripedium Lowii.

Of course there is a house devoted to Odontoglossum Alexandræ and the allied species, Masdevallias, and others of the cool section. This is a span-roofed pit, and the plants are placed very near to the glass. There are some grand specimens of O. Alexandræ, of which no two plants are exactly alike. Everybody who has the means should grow this by the dozen or hundred if they can, as it thrives in even a cooler treatment than the Masdevallias, 40° to 45° being sufficient to winter them in, and if the temperature fall to 35° even, no harm will ensue; besides, they may be had in flower every month in the year.

Oncidiums were represented by the rare O. Rogersii, and the singular and beautiful O. Papilio, of which there were many magnificent forms, whose flowers resemble a butterfly on the wing.

In a small house were a number of plants in good health of Epidendrum erubescens. It is a very difficult plant to manage, and is generally grown in a cool house fixed on blocks of wood. Mr. Anderson had planted it out on a level surface in a medium of sphagnum moss.

The cool and tropical show houses at the time of my visit were very gay; no doubt they are kept so "all the year round." In the cool compartment Odontoglossum grande in many varieties were truly grand, rivalled only by the magnificent Vandas in the East India division. Zygopetalum maxillare was producing freely its pendant spikes of distinct flowers. Epidendrum vitellinum was rather past, but it was yet conspicuous with its very distinct orange-scarlet flowers.

Passing to the tropical show house, the distinct and recently-introduced Cattleya Dowiana was not yet over, nor C. Aclandiæ, which was also in flower. Of Aërides suavissimum, two handsome varieties were in flower. Magnificent specimens of Vanda tricolor and varieties were ranged down the centre stage; also Vanda cærulea, of small size, but producing nice spikes of its large pale blue flowers.

Vanda suavis.

Many species of Ladies' Slipper are grown. These are at all times interesting, as the leaves of most of them are prettily marked. I noted Cypripedium Dayanum, a most distinct and beautiful species both as regards its beautifully-variegated leaves and flowers. C. Farricanum is also very pretty and distinct.

I will conclude by advising all lovers of this class of plants to visit Meadowbank, and by thanking Mr. Anderson for his kindness in showing me through, and unreservedly answering all the questions I put to him concerning the treatment of his favourites.—J. Douglas.

BOWOOD.—No. 2.

The Seat of the Marquis of Lansdowne.

We left off at the kitchen garden. This is situated on the north side of the mansion, and contains 5½ acres within the walls, which vary from 12 to 14 feet in height; the area included by them is divided into four compartments. There is, besides, in another part of the grounds a kitchen garden of about 2½ acres, in which Cabbageworts, Asparagus, Sea-kale, Rhubarb, Potatoes, and similar crops are grown; there is also an orchard of 6 acres. The soil and subsoil of the walled garden are naturally unfavourable to the growth of fruit trees, containing a large amount of hungry, coarse, ferruginous sand, with rock beneath, through the fissures of which the water rises to within 3 feet of the surface. On this account the borders have for the most part been formed artificially of turfy loam, which had to be carted a distance of several miles. These borders are generally 12 feet wide, and the great labour which has been expended in making them has been repaid by excellent crops. The trees have evidently been carefully managed from their youth, and among the horizontal-trained Pear trees are some of the best examples of that mode of training anywhere to be found. On the opposite side of the 9-feet walks, all of which are edged with stone, are also horizontally-trained Apple and Pear trees on espaliers of iron wire, and the space between them and the walk was in one border planted with Picotees and Carnations, to furnish cut flowers. The fan-trained Pears are large, and like the horizontals very well trained; so, too, are some single and double upright cordons between the trees. The Peach and Apricot walls have copings which project on the south side 4 inches beyond the face of the wall, and temporary copings are put on in spring. One wall is entirely occupied with Green Gage Plums, and on a north aspect are Plums for late use, and Morello Cherries, and borders with the same aspect are planted with Currants, which are kept covered to retard them in order to afford a late supply, and Lily of the Valley for forcing. On some of the walls are Fig trees, several of which though very old still bear good crops. To break the force of the wind Arbor-Vitæ hedges extend across the borders in parts exposed to the sweep of eddying breezes, and in front of some of the houses similar hedges are employed with the same object.

We will now look through the vineries and other houses, which are for the most part lean-to's facing the south. A half-span Muscat house 30 long, and a large vinery planted with Black Hamburghs, which are generally started about Christmas, may be dismissed without further remark, than that at the time of our visit each was filled with Geraniums. In the late Muscat house the Vines had been lifted in 1870, and a fresh border made; they had pushed roots vigorously, and the crop, about half of which was cut, was also good. The late vinery contained such standard kinds as West's St. Peter's and Lady Downe's; and a house planted with Canon Hall Muscat, a noble Grape when well grown, but a shy setter, was undergoing repair. Mr. Scammell prefers fruiting it on the young wood instead of on the spurs. In the early house the spur-pruned Vines were breaking at Christmas; on the back shelf were Strawberries for March, and in front Orange trees. A succession house contained Black Hamburgh and Buckland Sweetwater for ripening in June. Another range about 50 feet long by 15 or 16 feet wide, is filled with large old Black Hamburgh Vines, which it is intended to replace with Lady Downe's and other late Grapes. At present it is occupied with Chinese Primulas, Cinerarias, and bedding plants. The last vinery to be noticed is one fine-heated, containing old Vines lifted the year before last (1870), and which bore a good crop last season. This likewise was profitably occupied with bedding plants, Azaleas, and Mignonette.

Of the Peach houses, three in number, the trees in the earliest were coming into flower at Christmas, and will most likely produce fruit the first week in May. This house, about 9 feet wide, has a steep roof well calculated to transmit and not reflect the sun's rays early in the year, and so to economise natural heat; still ample provision is made for artificial heat, for there are three rows of 4-inch pipes. At the back are two shelves under the hip where Strawberries are forced. The trees in the succession house, which is flue-heated, had just been tied-in; the varieties were Royal George and Bellegarde Peaches, and Murrey Nectarine. Those in the late Peach house, being dormant, call for no remark.

The Pine pits, which are about 13 feet wide, and have outside chambers for leaves to afford bottom heat, contain a fine stock of healthy fruiting and succession plants. Black Jamaica and Smooth-leaved Cayenne are the varieties chiefly grown for winter fruiting, and the Ripley Queen for summer. Providence is also ripened to a good size. In other forcing houses were Dwarf Kidney Beans, Asparagus, and a number of Pines, every inch of space being fully occupied. In the Cucumber house, 30 feet by 12, Telegraph was bearing well; Azalea amœna, a charming little kind for spring decoration, was likewise being forced, as well as Gardenias and some other plants. One of the most useful structures in the garden is the orchard house, a little more than 200 feet long by 10 feet wide, and having a curvilinear roof placed against a wall facing south. The back sashes lift to afford top ventilation, and those in front are pivot-hung to push outwards. Peaches and Nectarines are trained on a curved trellis in front. Half a dozen Plum trees, taken from the open ground, beheaded, and grafted with Green Gage, had borne well last year. The other occupants of this house were Strawberries, to be protected until required for forcing, and Cos Lettuces, of which a large number had been taken up from the borders to be planted out in spring. In a quarter snugly hedged round with Arbor-Vitæ are frames filled with a fine healthy stock of Neapolitan Violets and half-hardy plants, pits for Strawberry-forcing, &c.

Plant-growing is not pursued to any great extent at Bowood, the principal object being to produce plants to meet the large demands for the decoration of the mansion and flowers for bouquets and similar purposes. A small stove contains Bougainvillea glabra planted in a border with bottom heat, and freely producing its rosy bracts on the roof; also a number of plants of the brilliant and useful Poinsettia pulcherrima in 4-inch as well as in larger pots. Dracænas, Marantas, Euphorbias, Eucharis amazonica, Begonias, and other plants. Another plant house is chiefly filled with Azaleas and Camellias; on the roof is a plant of Tacsonia Van-Volxemi, which flowers from spring till late in autumn. Outside of this house is a flourishing plant of the New Zealand Flax, which though almost hardy is not quite so, being cut down to the ground in severe weather unless afforded a little temporary protection. In front are two large tufts of the Pampas Grass, one of which had produced the year before a hundred of its tall silvery plumes. The only other houses we need notice are a temporary orangery, in which are some immense trees obtained from France, weighing with the tubs and soil more than 3 tons each, and, consequently, very troublesome to move to the terraces in summer, and another orangery forming part of the mansion, and as architectural in its character as the one just referred to is not. Here, too, are some large and handsome Orange trees in tubs, Bays, American Aloes, &c. Outside the Pomegranate, Bignonia radicans, and Japanese Honeysuckle serve to clothe the walls. The fruit-room, 50 feet long by 14 or 15 feet wide, is fitted-up with open-sparred shelves, and there are sliding shutters in the roof, which, except when fruit is required, are kept closed and the room in darkness.

We have before said that the glory of Bowood is its pleasure grounds, and we have also remarked how well these are kept notwithstanding their great extent; but it would not be just to the excellent gardener, Mr. Scammell, to omit adding that the useful is as carefully attended to as the ornamental, and that the fruit and kitchen garden and hothouses, as regards neatness and good cultivation, are on a par with the pleasure grounds.

Cultivated Nature.—Between Nature in her wild state and Nature under skilful management there is as much difference in appearance as between a savage and a peer, and in productive power as between a wandering Caffre and a practised artisan. A few days ago we went through Mr. Crook's gardens at Blackpill, and were astonished to find in it an Apple tree—the Crook Seedling, as it is now to be called—bearing a third

crop this season. Previously we had examined another—the Peach Apple, bearing its second crop—no scanty sprinkling of fruit, but in both instances to be reckoned by hundreds. Mr. Crook then showed us some Pumpkins, one of which weighed 130 lbs., and six of which weighed 5 cwt.! He then let us see a marvellous breed of ducks—the West Cornwall (the grandpapa of which had been given him by Captain Ford of Swansea), in one of whose nests in the garden he had a few days previously found fifty eggs! The strong presumption is that they were all laid by one duck, as the daily produce of the others had been duly accounted for. The same lucky cultivator of Nature avers that he has a hen which has scarcely stopped laying for the last twelve months, has not moulted during that period, and is laying now! Has the golden age begun? People had better go to Mr. Crook to learn "how to make fowls pay."—(*The Cambrian.*)

MRS. PINCE GRAPE.

I would not trouble you with any remarks about this Grape had I not formed a very different opinion of it to that of Mr. Donaldson. He declares that he has no hesitation in saying it is the best late black Grape in cultivation. I know Mr. Donaldson is a good Grape-grower, and his opinion ought to be worth something to Vine-planters; but if he has formed it from the Vines under his own care, and from the state and appearance of the crop at this time of the year, I think that he is premature.

This is not the time either to condemn or praise a Grape for its late-keeping, as many others as well as myself have not yet ceased sending to table the old Black Hamburgh, which is well known to be anything but a late Grape. If Mr. Donaldson succeed in keeping his crop of Mrs. Pince Grapes fresh and plump in berry until the middle of next March, he will have accomplished what very few, if any, have hitherto done; and if he send a dish to the Fruit Committee in that month, so that it may be compared with the Lady Downe's Grape, he will induce many gardeners to alter their opinions about this Grape, and deserve the thanks of them all. Mr. Donaldson says this is the first year he has succeeded in growing them to perfection, as neither in the first nor second year of fruiting were they satisfactory; therefore I am inclined to think that the age of the Vines has something to do with bringing about these good results. It is well known that if a Vine produces better fruit at one particular part of its life it is pretty sure to be when it is young. I nevertheless admire Mr. Donaldson's skill, and hope to see more of the Grape towards the spring.

I agree with much of what the Editors say, for I have known opinions expressed about new Grapes when there has been only the raiser's notice to signify that a new Grape was to be sent out, to say nothing of the adverse opinions of it after it had been seen, but not tried. I believe Mrs. Pince was thus-treated by many at first, but most of those gardeners who had the opportunity of trying it did so, and I know of some really first-rate Grape-growers who applied the utmost of their skill in order to prove its title to being the best late black Grape, but failed at the last to discover its pretensions. There is no lack of vigour in the Vine, and with care it has been found to set its fruit well, and swell-off evenly. The flavour is known to be good, but its great failure appears to be in the colour, which cannot compare with that of Alicante and Lady Downe's, and before the new year comes in, it shrivels-up so as to become unsightly, while all other popular late sorts are plump, fresh, and good.

I do not myself grow Mrs. Pince Grape, but the above description is taken from what I have witnessed in a dozen places this autumn and winter, so that Mr. Donaldson has reason to be proud of his crop, and no one wishes more that he may succeed in preserving it plump and fresh throughout the next two months than—Thomas Record.

NOTES ON THE LILIES.

Thanking my friend, Major Trevor Clarke, for the good information which he has given us (page 10), I proceed to answer his queries as to Lilies seeding. Here, at Weybridge, L. auratum seeds freely out of doors, L. longiflorum occasionally. In the orchard house, L. auratum, speciosum, and Wilsoni seed freely. Of L. pendulilorum I had one good seed-pod. L. longiflorum seeds freely. By the same token we have now in a seed-pan a beautiful flower just expanding; the seed was sown November 26th, 1868. I have, unfortunately, lost the register of the father, but I am almost sure that the L. longiflorum was impregnated by pollen either of L. Wilsoni or of a very fine variety of L. Thunbergianum. The seedlings are very strong, the leaves larger than those of L. longiflorum usually are, and the stems quite dark, but otherwise I can so far detect no change. The reason for the late blooming of the present flower appears to be this: One of its sisters bloomed beautifully in early summer, the new blooming stem was then growing weakly as though the seed-pan was deep, the earth was not enough for all the pulls on it, and the roots were all away among the crocks at the bottom, so we wedged the pan down into a half lard-keg filled with good peat; the plants then all went ahead.

Since my last notes (page 502), there has been an addition to the beautiful family, in the shape of three if not of new species, at least of very distinct varieties of Lilies imported by Messrs. Teutschel, of Colchester. Two of them, called A and B, differ only in size and, perhaps, width of opening; they are, in the drawings exhibited, a purplish-pink-shaded compound of L. longiflorum and L. auratum without spots or bands. I hope some other grower will keep the ball rolling. The now happily-expanded Journal "gives ample room and verge enough," the characters of L. to trace.—George F. Wilson.

OBSERVATIONS ON CAULIFLOWERS.

In regard to this useful vegetable, the past few seasons have not been without their instructive lessons as to the soils and other circumstances most suited to its successful cultivation. From 1868 to 1870 inclusive, excessively dry summers have been the lot of at least a great part of the United Kingdom—a state of things very trying, to say the least of it, to the vegetable-grower. Prominent amongst a goodly list of garden crops which suffer severely from drought stands the Cauliflower; and in very light soils the effects (which many a gardener knows no doubt frequently to his cost) are most clearly illustrated, especially if such soils be shallow and gravelly. The best, I had almost said the only, remedy in such circumstances is thick mulchings of the best material that can be spared—if rotten manure, so much the better—and copious supplies of liquid manure at stated intervals during the drought. In fact, unless the soil be approaching to deep clay, mulching may be judiciously practised with every hope of good results. In 1869 we found plants treated in this way far surpass those that had the benefit of the "latter rain," planted only a fortnight later. The old system of potting a number of plants in autumn, and protecting from frost in any cold plant-structure, is an excellent way of securing early produce; but they should not by any means be allowed to get pot-bound, as is sometimes the case. This can be avoided by not using too small pots. Use 3-inch pots instead of the smaller sizes, which are generally as often used. When weather is unfavourable for planting in spring, the plants suffer less from drought in the large pots. When dry pot-bound plants are put out, buttoning invariably follows. The past season here has been more favourable for second and third plantings than it has been farther east for the last three years, but late plantations have been a failure. I attribute this to the prevalence of heavy cold rains almost incessantly from end of June to August; while in seasons immediately preceding, the heat of the earth counteracted the cooling tendency of late rains, and these were therefore beneficial to late crops. The vegetable quarters here are objects of more interest to the proprietor than the plant houses, which fact has led me to pen the foregoing notes on one of a variety of vegetables demanding most of our resources, and which may interest some of your readers.—David Mackie, *Dunlossit Castle, Islay* (in *The Gardener.*)

MARÉCHAL NIEL WORKED ON GLOIRE DE DIJON FOR FORCING.

Let me recommend anyone who loves this glorious Rose to force it when worked on the Gloire de Dijon. I bought a quantity of trees in pots, and put them in heat in October, and on Christmas-day they began to bloom, and on January 4th I picked the finest bloom I have ever seen. I have never, since I began to grow Roses, been so delighted with anything as the way in which these Maréchal Niels are blooming. I have them budded on the Briar in the same pit, but the size and form of the blooms is not to be compared with those of the former trees. Will Mr. Radclyffe tell me what Roses, mentioned in

the lists he refers to, will not do on the Manetti stock? Of course I do not allude to Teas.—J. B. M. Camm.

STRAWBERRY CULTURE AND VARIETIES.

Your correspondent "T. G." (see page 9), invites discussion on this fruit. My experience on Strawberry-growing ranges over thirty years, during that time I have grown them in many parts of England—in the stony stubborn land of Sussex, the gravelly soil of Kent, and the blowing sands of Surrey, and I have been successful with them in all places, consequently I believe Strawberries can, with proper treatment, be grown anywhere.

As an illustration of what may be done with Strawberries, I may mention that the Rev. H. Charlton, rector of our adjoining parish, Easten, told me he had been at Easten twenty years, but could never grow good Strawberries—the soil being too light. I gave him the same advice I give everybody—namely, dig deeply, manure heavily, plant early, and never allow the plants to remain after the second crop. This he has done with the very best results; in fact the fruit grown by him last season was generally admired.

Dr. Hogg Strawberry here is really something to admire—fine large showy fruit of most excellent flavour, also a prodigious bearer.

My favourite six varieties are British Queen, Dr. Hogg, Black Bess, a variety too little known, Frogmore Royal Pine, Sir Charles Napier, and Keens' Seedling. If I were asked which I consider the best Strawberry grown, I should, without any hesitation, answer, Sir Charles Napier. To see its yearling plants averaging two hundred flowers to each plant when ripe, is a sight not easily forgotten, and it gladdens my eyes yearly. —R. Gilbert, *Burghley*.

The praises of Dr. Hogg Strawberry have been so much in everybody's mouth, and dropping from everybody's pen, that it sounds rather astonishing to hear from anyone that it has caused disappointment; still it seems now to be about to undergo the same ordeal as nearly all other novelties.

To state my own experience of it, I must say it entirely coincides with that of your correspondent in last week's impression. Until I saw these remarks I refrained from saying anything against a variety that seemed to be of universally recognised merit, and I thought that the plants which I had must have been spurious. This opinion may be correct yet, therefore I am anxious to know whether others have experienced similar failures. Three years ago, relying upon public testimony, I planted along with other sorts ten rows of Dr. Hogg Strawberry, about 50 yards long; all the other sorts grew very well, and bore well the following summer, but I was very much disappointed with the behaviour of Dr. Hogg. The plants made but a poor and stunted growth, and what fruit they bore certainly had a resemblance to that of British Queen, but the berries were so few and far between as not to be worth gathering. The ground received no other preparation but manure dug-in in the ordinary way.

Although my faith was somewhat shaken, I tried to see what kind treatment would do. I selected a piece of ground that I thought suitable, had it trenched 2 feet deep, and the subsoil dug over in the bottom with a liberal dressing of manure. This operation completed, a good dressing of rotten manure and a quantity of half-inch bones were dug into the top spit. The best runners that could be procured of this and other varieties were planted in this ground last spring; these are Keens' Seedling, President, Myatt's Eleanor, and another early sort of which I have not the name, all of which made a good growth last summer. I regret to say, however, that Dr. Hogg Strawberry, if it is that variety which I have, shows the same poor stunted growth as in the former situation. I intend to let it remain to see how it turns out. Should it be no better than I expect, I shall bid good-bye to that variety for ever.—A Yorkey.

COOKING POTATOES.

Having tried various ways of cooking this valuable esculent, all more or less faulty, a short time since the following method was recommended to us; and as it combines simplicity with economy, perhaps some of your numerous readers might like to try it. Take a very narrow ring of the skin off the Potatoes before boiling (in kidneys the ring should be taken long ways), and when they are ready for table the remainder will fall off in two pieces, leaving the Potatoes like "flour-balls." We have found Potatoes so treated much better than when boiled without the skin being cut; and as the skin leaves the Potatoes in the process of cooking, it does away with the objectionable method of peeling afterwards. We also adopt the practice of putting new Potatoes in boiling water, and matured ones in cold water, not forgetting the salt in either case.—(*The Gardener.*)

THE ROYAL HORTICULTURAL SOCIETY'S EXAMINATION OF GARDENERS.

The following are the results of the examination of gardeners, held on December 12th, 1871:—

	Fruit and Vegetable Culture.		Floriculture.	
	Marks.	Certificates.	Marks.	Certificates.
1. C. Adams, Retford	390	3rd.	390	3rd.
2. William Falconer, Royal Gardens, Kew	910	1st.	1080	1st.
4. John Jones, Royal Gardens, Kew	1140	1st.	1100	1st.
5. James A. Smith, Royal Gardens, Kew	930	1st.	740	2nd.
6. Charles Herbert, R.H.S. Chiswick	730	2nd.	460	3rd.
7. A. W. Maynard, R.H.S. Chiswick	660	2nd.	700	2nd.

The Examiner in Floriculture reports that Nos. 2 and 4 have given very intelligent replies to the questions.

NOTES AND GLEANINGS.

Messrs. Carter & Co. offer at the Royal Horticultural Society's Meetings in 1872 the following prizes for vegetables (to be grown by gentlemen's gardeners, or amateurs, without forcing, in the open ground):—March 20th, first prize, £1 10s., second, £1, for two brace of winter Cucumbers, to include Carter's Champion. May 15th, first prize, £1 10s., for a dish (half a peck) of Carter's First Crop Pea; second, £1, for a dish (half a peck) of early Peas, any variety. June, at Birmingham Show, the "Carter" Challenge Cup, value £52 10s., and first prize, £10, second, £3, for a collection of vegetables (twenty-four dishes), to include as follows:—Half a peck each of Laxton's Alpha, Laxton's Quality, Laxton's Supreme, Carter's First Crop, Carter's White Gem, and Carter's Hundredfold Peas; Carter's Covent Garden Garnishing Parsley, Cox's Golden Gem Melon, Naseby Mammoth and Marzagole Onions, French Breakfast Radish, and Carter's Champion Cucumber. July 17th, first prize, £2 2s., second, £1 1s., for three brace of Cucumbers, and four dishes of Lettuce, to include Carter's Giant White Cos and All the Year Round. August 21st, first prize, £2 2s., second, £1 1s., for four dishes (quarter peck each) of Runners and Dwarf Kidney Beans, to include Carter's Champion Runners. September 18th, first prize, £2 2s., second, £1 1s., for three dishes of Beet, to include Carter's Perfection of Beets; and six dishes of Onions, to include the New Giant Rocca, New Giant White Tripoli, and New Red Italian Tripoli. October 2nd, first prize, £2 2s., second, £1 1s., for six dishes of Potatoes—namely, three dishes of White or Pink Round Potatoes, and three dishes of White or Pink Kidney Potatoes, to include Carter's Ashtop Fluke. November 6th, first prize £2 2s., second, £1 1s., for dishes of the following:—Carter's Little Pixie Savoy, Carter's Garnishing Kale, Brussels Sprouts, and Carter's Dwarf Mammoth Cauliflower. December 4th, first prize £2 2s., second, £1 1s., for a collection of vegetables (twelve varieties), to include Parsnips, Lecks, Salsafy, Scorzonera, Carter's Perfection of Beets, and Carter's Dwarf Crimson Celery. The conditions may be had from Messrs. Carter.

A NEW WAY TO MAKE FRUIT TREES.

Mr. Sullivan Hutchinson, of Bristol, N. H., received letters patent last May for a new and novel invention for making productive fruit trees in a single year from fruit-bearing limbs. Limbs that can be spared from trees that bear desirable fruit are transformed into independent trees which will bear right along, just as though they had not been severed from the parent stock, and in a short time become fine thrifty trees, retaining the habits of the trees from which they were taken. This is what Mr. Hutchinson claims his invention will do. From the imperfect description we have had of the process, it is impossible to give a very clear idea of how the thing is done. Into the limb, however, which is intended for the future tree, small roots are grafted just above where the limb is severed. Below these roots the branch is girdled. About and below the roots is placed a box filled with earth. This operation is per-

formed in the spring. During the summer the roots grow, and life is thus established between them and the limb above. In autumn the limb is severed at the place where it was girded, and set in the ground in the same way any young tree would be. The next year, according to Mr. Hutchinson's statement, this new tree will bear fruit just as though it had not been cut from the parent tree.

To what extent this operation may be carried, and how successful it may prove, remains to be seen. We have no doubt Mr. Hutchinson has demonstrated that the new trees will produce fruit at once, but we suppose sufficient time has not elapsed since his experiments commenced to determine what effect early bearing may have upon their future growth. That a young tree can bear fruit to any extent and at the same time put on a vigorous and thrifty growth, is not in accordance with our observation. And we suspect that Mr. Hutchinson will fail to produce very healthy trees from the application of his new discovery. We shall expect in a few years to hear that his trees have died; or at any rate that they have become so feeble that they will cease both to produce fruit and to grow. If it shall prove otherwise, the discovery is an important one.

Experiments to a considerable extent have been made in Bristol and New Hampton, and we hear that farmers in various parts of the State are buying town and farm rights with the intention of testing the practicability of this new system of producing early-bearing fruit trees. If successful, a complete revolution in our manner of obtaining Apple trees will be the result. Instead of buying trees from the nursery which require from ten to twenty years to come into bearing condition, the limbs from our old trees will be converted into new ones that will give us fruit at once. While we have no great expectations in regard to this new process, we have thought it of sufficient importance to call the attention of our readers to it, who can for themselves make such inquiries and investigations as the subject would seem to merit.—(*American Gardener's Monthly.*)

SOOT FOR ORANGES—ORANGES UNDER VINES.

I SEND a portion of a twig, and also an Orange, to show the effects of a free use of soot for top-dressing the pots in intensifying the colour of both leaves and fruit. The twig is taken from a Silver Orange; the fruit I had from a St. Michael's, but the skin is thick, although the pulp is sweet.

These Oranges have been under my Vines in the vinery all the year round, the heat during the last two months has been kept at about 50°. I have Tangierine Oranges in the same house ripe and sweet, the leaves equally green and luxuriant. I use the syringe frequently, and often apply liquid manure, which carries down the soot from the surface of the pot.—J. C. BARNHAM, *Norwich.*

[The foliage of the twig was intensely dark green and healthy. The fruit small; rind very thick; and flesh juicy, sweet, well-flavoured, and seedless.—EDS.]

"LES PROMENADES DE PARIS."

WE concluded our last notice of M. Alphand's splendid work with the Grande Cascade de Longchamps; and not inappropriately do we return to the subject with a view of the Grand Lac of the Bois de Boulogne. This great lake was dug out in 1853 and 1854, and although in a somewhat permeable soil, it has remained quite perfect. It occupies a superficial extent of 190,000 metres, or about forty-three acres, and it contains two islands of the extent of 80,100 square metres. To prevent the soakage of the water the sloping sides of the lake have been built with calcareous blocks up to the edge of the water, and the bed is formed of a layer of concrete 4 inches thick, well rammed, and then plastered over with a coat of mortar 1¼ inch thick. The mortar is composed of three parts sand and one part hydraulic lime. The concrete is composed of two parts of this mortar and three parts of siliceous gravel.

We come now to Chapter VI. in our analysis of the book, and this we find devoted to the forest plantations, turf, and gardening works of the Bois. This part is very richly illustrated with portraits of the finest specimens of trees, and of the landscape effects produced by the skilful grouping of the forest and ornamental trees used in the planting. Among the finest of the former are *figs.* 33 and 34, Thuja gigantea and Araucaria imbricata, and fine specimens of Cunninghamia sinensis and Larix europæa pendula, of which we reproduce the figure. Not the least interesting and instructive of this chapter is that portion which treats of planting the avenue trees, and the use of the protectors and supports; also the manner of transplanting large trees, which is very fully illustrated, and which is performed with an apparatus which appears to be at once simple and effective. One of the most useful parts of this chapter to the practical man is that which treats of the clumps and the style of planting, with a list of the trees, shrubs, and flowers with which each is planted, and also of the flower beds distributed throughout the Bois.

Chapter VII. is devoted entirely to architectural works, with ground plans and elevations of the lodges, gates, summer-houses, and restaurants that are distributed throughout the Bois. Chapter VIII. treats of those parts of the Bois which have been leased out for special purposes; one of these is the Pré Catelan, a reserved piece of ground consisting of about seventeen acres, which was enclosed by the city of Paris, and converted into an ornamental garden, with places of amusement, buffets, aquarium, dairy, photography, music, and all manner of attractions. The racecourse of Longchamps is another of these, a skating establishment is a third, and, perhaps, the most important of all to our readers will be the Jardin d'Acclimatation. Those who have seen and remember that charming retreat find here a lasting representation of that which we believe suffered, perhaps, more than any other part during the sad events which occurred during the past year in Paris. The close of this chapter is occupied with very useful details and illustrations of the ice-houses in the Bois. We shall not dwell on the following chapter, which is entirely given up to the formation of the Artesian wells which supply the whole of the water for the Bois—works of wonderful engineering skill and ability. Here every detail is given of the machinery and apparatus employed.

Chapter X. introduces us to that wonderful gardening establishment of the city of Paris, La Muette, lately the scene of the great strife between the Commune and the Versailles troops. M. André thus described La Muette in our tenth volume:—

"Situated near one of the entrances to the Bois du Boulogne, the La Muette gate, at the extremity of the fashionable quarter of Passy, this establishment covers an area of nearly five acres between the Rue de la Tour, the Avenue de l'Empereur, and the old historical castle of La Muette. The railway between Auteuil and St. Lazare cuts the ground into two unequal parts, of which the smaller is taken up by frames, the orangery, sheds, cellars, &c.

"The frames are more especially intended for raising plants from seed, and for the extensive propagation of softwooded plants for bedding, such as Pelargoniums, Verbenas, Calceolarias, Salvias, Fuchsias, Chrysanthemum frutescens, &c. There are altogether 2900 lights set in straight lines, and arranged in sections according to the description of plants grown in each. The frames are shortly to be replaced by a range of fifty low houses communicating with each other, and forming the most complete assemblage of glass houses ever seen. Each section is in charge of an under-foreman under the general direction of the foreman, and he has two or three assistants, with whose aid he has to manage from 100 to 150 lights. He alone is responsible for the plants, also for the breakage of glass, and other casualties arising from carelessness, and as a compensation he receives a small monthly allowance. The advantages of this system are, that the workman takes better care of the plants and materials committed to his charge, economy is consequently secured, and the men, being confined to one department, speedily gain great experience of the particular plants with which they are engaged. To give an idea of the immense number of plants raised at the Fleuriste de la Meutte (that is the name of the establishment), I may state that it amounts to nearly 3,000,000 a-year, Pelargoniums alone counting for 290,000, Cannas for 70,000, and other principal genera in proportion.

"The orangery or conservatory, constructed in a very economical manner, is 226 feet in length, and is used for the protection in winter of hardwooded plants taken up in autumn for planting-out in the following year. A large shed of the best construction serves to shelter soils, peat, and various composts, as well as spades, rakes, watering-pots, and light tools. Down the middle for the entire length of the shed runs a table 13 feet wide, at which sixty men can pot with freedom the innumerable plants struck from cuttings in the frames. Spacious cellars, 9 feet 10 inches high, cut out of the rock at great expense and at a considerable depth below the surface, extend beneath the frames. They are intended for protecting

in winter tubers and rhizomes, such as those of Dahlias, Cannas, &c., taken up in autumn. They may also be used as a workshop for the gardeners in severe frosts, and as gas will shortly be laid on, they will be still better adapted for the purpose.

"On the other side of the railway are the trial ground and glass houses. Whenever a new plant is announced it is purchased at any price, and here tried, for the city of Paris will not lag behind in the race of gardening progress. If the plant is hardy it is grown on trial out of doors along with kindred plants, and under different modes of culture, and after two or three years' experience it is adopted or rejected; but it must possess many good qualities to dethrone its rivals, and be extensively propagated. The effect is here studied, especially in masses of one species or variety, rather than in heterogeneous assemblages of plants without unity or harmony. The trial is all the more severe, because long experience has taught mistrust of the high-sounding, often specious, descriptions given by dealers in novelties. If the plant is adopted it is sent to Vincennes, where it can be propagated in such numbers, and over an extent of ground, that it could not be at La Muette.

"The houses, which have been successively erected from 1858 to the present time, are not equalled in extent in any other part of France. They consist of twenty-one ranges, divided into sections according to the mode of culture required by the different classes of the plants, and cover an area of 95,800 square feet. The largest house has an area of 18,222 square feet, is 31½ feet in height in the centre, and is in three compartments. The central one is filled with a splendid collection of Camellias from 15 to 23 feet high, planted out, and several of them once formed part of the celebrated collection of the Empress Joséphine at Malmaison. Of the two side divisions one is devoted to the protection of those ornamental-foliaged plants which have risen so much in favour during the last few years. There may be seen trees of Wigandia, Nicotiana wigandioides, which is covered in winter with superb drooping panicles of white flowers, Montagnæas, Polymnia, Aralia papyrifera, and many other handsome tropical plants. The division on the other side contains a number of large specimen Palms, Pandanuses, and Cycads, which are almost unrivalled. Among them are magnificent examples of Sabal Blackburniana, Seaforthia, Pandanus, Phœnix, Thrinax, Livistonia, Zamia, Cycas, Ceratozamia, &c., not to mention a numerous collection of novelties, in fine condition, amounting to upwards of 390 species. Another large house, in three spans, holds the remainder of the collection of large Camellias; these are in tubs, and while those planted out afford a multitude of cut blooms, these are used to decorate the apartments of the Hotel de Ville at the great balls given by the Prefect of the Seine; indeed, all the large stove and greenhouse plants are principally grown for this purpose. Ordinary greenhouse plants, such as Azaleas, Acacias, Epacrises, Heaths, &c., are grown along with the Camellias, and receive much the same treatment as regards culture.

Larix europæa pendula.

"A square pavilion, filled with very tall Palms, Dracænas, Ficus, Aralia, &c., forms a vestibule to a high lean-to containing a collection of no less than 110 species of Ficus. Ficus elastica (Urostigma elasticum), or the Indianrubber tree, takes up the greatest amount of room, although there are some other species of nearly equal merit for beds of peat soil out of doors in summer.

"Further on, in sections according to the description of plants grown in them, are large and fine houses devoted to Dracænas, to Aroids, to Ferns, to large-leaved Solanums, to Begonias, to Musas, to Hibiscus, to Pelargonium grandiflorum, to large Caladiums, &c. Lastly, other two houses deserve special mention; these are the propagating-house and that which goes by the name of the 'serre de sevrage.'

"The propagating-house is employed for the rapid propagation of all those hothouse and hardy plants that do not strike readily in frames, and the appliances are such as are nowhere else to be seen. It is impossible, however, to convey a clear idea of the arrangements from mere description; suffice it, therefore, to say that there are shelves all round, and, besides, two bark beds, in the interior of which shelves rise in gradation like the steps of a stair, and under these run the hot-water pipes enclosed by sheets of iron. The pipes, sixteen in number, are 4¾ inches in diameter, and run all round the house. Being thus confined within the pit they maintain the heat of the tan in which the pots are plunged, and afford that degree of bottom heat which is so favourable to the emission of roots. The step-like arrangement of the shelves covered with tan, on which bell-glasses are placed, allows of the young plants being kept very close to the glass. Six young gardeners are employed through-

Grand Lac, Bois de Boulogne.

out the year in propagating, and for plants difficult to strike or raise from seed special means are provided. This house furnishes about a million of young plants every year.

"The 'serre de sevrage' is that in which the young plants are placed as soon as they have recovered from their first transplantation or potting, and when they are well established they are removed to their respective houses or frames to make way for new comers. A portion of this house is occupied with choice specimens of new stove plants on trial, or for propagation.

"I may add that the other branches of this establishment, such as seed-rooms, storehouses, &c., are well organised, and that the regulations are most judicious, and so, too, are those with regard to the superintendence, order, and discipline of the men. Lectures on the theory and practice of horticulture are periodically given by the heads of departments to the workmen and apprentices, and discussions held. The expenditure for this great establishment does not exceed £8800 a-year."

WORK FOR THE WEEK.

KITCHEN GARDEN.

As has been before stated, spare ground should now be dug and ridged; indeed, trenched, if time permit. Where a systematic rotation of crops is carried out, it is an excellent plan to trench all the kitchen garden successively in the course of three years. The trenching to be performed in each year, should be on the ground intended for tap-rooted plants—such as Carrots and Parsnips; and in forming new plantations of Strawberries, Raspberries, and bush fruit if the subsoil be stiff, sour, and wet, work it well up, and drain it. A good coat of cinder ashes well worked into it, serves to facilitate the passage of water and air. Thorough drainage should be performed at once, as now there is more ground vacant than at any other season of the year. If the ground have a gentle slope to the south, the main drains should be formed against the descent at the depth of 3 feet 6 inches. They are of round draining tiles 2 inches in diameter, and at the distance of 40 yards apart, with a layer of broken stones 4 inches in thickness, and a thin covering of heath turf to prevent the earth mixing with the draining materials above. Side drains should be introduced 2 feet 6 inches deep, and about 16 feet apart, with tiles 1½ inch in diameter, on the same principle as the main drain. Manuring and trenching must follow afterwards. *Cauliflower* plants under hand-lights will now require surface-stirring and a dressing of charred material. The same treatment will be found alike beneficial to the plantations of early *Cabbages*, to preserve them from the ravages of slugs. Any vacancies in the *Herb* beds should in favourable weather be replenished, and if new plantations are required, an accessible situation should be chosen in consequence of the frequent demand for them. If former directions have been carried out in making sowings of *Peas* and *Beans*, second sowings might now be made of the double-blossomed Early-frame Peas. This variety of Pea is better in quality than many of the newer kinds, and deserves a place in all gardens where choice vegetables are esteemed. To grow them in perfection there should be allowed 5 feet between the rows; a sowing of soot on the seed, and the drills filled up with some fresh loam, if any can be spared; and when the crops make their appearance, a dressing of charred materials will not only promote their growth, but will check the attack of slugs.

FRUIT GARDEN.

Fruit trees on the walls should have a good coating of half-decayed manure over the roots as a mulching, and where young trees of Peaches and Nectarines were planted fourteen months ago, if two wheelbarrows of charred ashes are now spread over the surface on the roots of each tree, this will encourage it to make an extraordinary growth during the following summer. Pruning, training, and nailing such fruit trees as furnish walls on the north and east aspects should not be delayed, if the weather prove fine. Espaliers, where repairs are necessary, should now be attended to, and the trees pruned and neatly tied with rope yarn. Raspberry plantations also might be staked, tied, and pruned, according to the strength of the canes. A large amount of manure applied to the surface will prove of great advantage to them in the bearing season. Cross [ill]-directed branches which prevent a free circulation of air or [sun] the bearing season should be removed, and newly-planted during [sh]ould be carefully staked to prevent friction when tied. trees sh[ould] ss require stimulating, a good dressing of half-de-If any tre[es] eayed dung should be spread over the surface as far as the operator considers the roots extend.

FLOWER GARDEN.

As the weather is unusually mild, arrears of autumn business can now be made up, and even a march stolen on the coming spring. In the flower garden little can, however, be done now except digging the borders and beds deeply to ameliorate the soil for clumping-out flowers. Any of these beds that are exhausted should have the soil renewed ready for spring work. In open weather laying turf may be proceeded with. See that all hardy plants are secured against severe weather. All Pink and Pansy beds must be looked after; those plants that are loosened in any way should be carefully fastened. The same observations will apply to seedling Auriculas and Polyanthuses. Carnations and Picotees will still also require regular attention, as they are said to be spindling in this mild weather. It will be better to allow the stem to remain on till later in the spring, watering occasionally when the soil is very dry, but avoid wetting the foliage as much as possible. Where turf is at all uneven it should be repaired before the end of next month, as, if lifted later than February, it might require some trouble to get it to take quickly. Unlevel turf is an eyesore, and it makes mowing more tedious and difficult; hence it is worth while to spare time to make whatever little repairs may be necessary here. Sweep lawns occasionally to clear them of fallen bits of branches, &c., and use the roller frequently here and on gravel to secure a firm, smooth surface.

GREENHOUSE AND CONSERVATORY.

During the present changeable weather the principal object should be to keep damp and mildew in check, which the weather we are now experiencing is likely to induce. Nothing keeps off these two evils so much as a dry, healthy atmosphere. To assist in promoting a free circulation of air through plant houses, some of the inferior duplicates might now be removed to spare vineries or other quarters, for the slightest approach to a crowded state among delicate plants will be sure to cause at least a partial loss of foliage. Let all descriptions of hard-wooded plants that have made sufficient growth, be kept rather dry at the root, in order to check their growth and induce a tendency to form bloom, but do not let the balls become so dry as to endanger the foliage. Look sharply after insects especially mealy bug, and endeavour to get the whole collection clear of this destructive pest, for if neglected now it will not fail to demand attention in spring and summer, when time with the plant-grower will, doubtless, be fully as precious. A temperature of from 40° to 45° at night, and from 50° to 55° during the daytime in the conservatory, is during this dead time of the year amply sufficient. Where twiners for covering the roof are grown in boxes or have but limited root room, as much of the surface soil as can be taken away without seriously injuring the roots should be removed annually, replacing it with some good rich fresh material; this cannot be done at a better season than the present. The conservatory or show house should very soon be full of floral beauty. Camellias, Luculias, Epacrises, Heaths, Primulas, Mignonette, tree Violets, Cinerarias, Indian Daphnes, and many other showy things, may easily be had in flower at this time, and with proper appliances a few Roses, and other forced plants, as Oranges, bulbs, &c., should be made to come in now. Let Pelargoniums now be kept as much at rest as possible, giving them but little water; in fact, none unless the leaves show a disposition to flag. In fine weather like the present they should, however, have plenty of air, but not in the shape of cold currents, which are apt to prove injurious to the leaves. A temperature of 50° by day, and 40° by night, will be sufficient for the present. Any of the stock from which many cuttings are wanted should, without loss of time, be removed to a light, warm situation, first washing the pots, and cleaning and adding a little fresh soil to the surface of the ball. Some kinds of Verbenas are very subject to mildew when placed in heat during the winter season, but this is easily kept in check by means of sulphur, only let it be applied the moment the pest makes its appearance.

FORCING PIT.

The pit in which flowers for the conservatory are forced, should possess at this period a permanent bottom heat of 80° with atmospheric moisture. Such being the case, preparations must be made for securing a due succession of early spring flowers, a sprinkling of the most favourite kinds of which may be forthwith introduced, such as Moss Roses and crimson

Perpetual Roses, hardy Azaleas, and plants of that sort. Hybrid Perpetual Roses will do better in a more moderate temperature.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The common and Veitch's Cauliflower were protected during the frost with litter, which was left banked-up against them even in fine weather. On looking over these we came upon half-a-dozen so hurt as to be useless, and also numbers with heads of from 2 to 4 inches in diameter, swelling well, and as white as milk, all of which would have been injured if no protection had been given. Mice and rats seldom meddle with plants put out in the open garden, but should these be placed under cover, they are at them immediately.

FORCED VEGETABLES.

Lately I have not been able to force *Dwarf Kidney Beans* in winter, but I would recommend them as being more tender than those grown in the open air, as making a pleasing variety on the dinner-table, and realising a handsome profit in the market. Our first out-of-door crop was planted out from pots in May, and the last sowed at the beginning of July in an earth-pit, to be protected in October, and gathered in the middle of November. Our first crop, under glass, we sowed in pots outside during September, and brought into a heated position about the middle of October. If it is necessary to grow them in pots afterwards, sow four or five Beans in 60-pots, and then transplant them to 6 or 7-inch pots, in which they bear heavily. After the middle of January we used 12 and 15-inch pots, but the largest produce in the darkest months of winter was always from smaller ones.

We had more produce from pots than from pits during the dark months, but from February and onwards that from plants in a pit was larger than that from those in pots occupying a similar position, though if the latter were well top-dressed there was but little difference between them. Those planted out, however, were on the whole better. A heated pit is preferable to a forcing house, as thrips and red spider are thus avoided. When thus grown in pits we used to have strong plants in 6-inch pots, which we planted thickly in rows from 2 feet apart. We often kept up successions by sowing in the furrows between, shortly after those in the rows had begun to bear. With a little fresh soil we have thus often had four and five successions in the same pit. When this plan is not adopted it is best to sow in 5-inch pots, and then plant them out as a piece of the old crop is cleared. An application of lime and sulphur upon the walls, pipes, and flues, with a plentiful syringing of warm soot-water on sunny days, are the best preventives against red spider and thrips. Newington Wonder, Sion House, and Robin's Egg were our favourite kinds. Sir Joseph Paxton, if obtained true, is a dwarf free-bearing kind. Kept-up successions of Sea-kale, Rhubarb, Asparagus, and Mushrooms. Rhubarb may easily be forwarded by means of a barrel set over the roots, or by half a dozen sticks put round a strong root and wrapped with a strawband, then light litter placed under, and a firm bunch of it stuck in the opening at the top. The finest and sweetest *Sea-kale* we ever had was obtained by covering the roots with 6 inches of bog earth, and placing a foot of fermenting material all round, and on the shoots appearing the crop was gathered. The next best obtained out of doors was by covering the ground above the roots with dry ashes and a little salt to deter slugs, and then laying over from 12 to 15 inches of clean sweet tree leaves, with a slight sprinkling of litter. When a little protuberance appears on the covering you may be sure that the shoots are from 6 to 7 inches in length, and will come through the leaves white and sweet; but on this plan no dung must be mixed with the leaves. In all cases where this is necessary the roots, or rather buds, should be covered with pots or boxes to keep the shoots clean and sweet. Direct contact with slightly warm leaves will not tell on the sweetness of the flavour, but we have always thought that direct contact with strong manure took away from the sweetness of the shoots. We generally grow all our earliest in the Mushroom-house, but we do not obtain such strong stubby heads as we do later on by the above simple means out of doors. The heads of Sea-kale should be stubby and branched, not more than 6 inches in length, from 1 to 2 inches in diameter at the base, and quite white with the exception of a tinge of purple at the points.

I think that last year I showed in some place the importance of using Sea-kale as an early out-door vegetable without any covering or blanching whatever. Previously, I had directed attention to the use of the flowers before they were too much expanded; but even these are inferior to the fine short shoots that come in spring and early summer, just showing the flower-umbel in miniature. If these are cut when short, and cooked, they supply an abundance of rich food, and there is quite time enough to put out new shoots to keep the plants well established. Even thus treated, without forcing and blanching in winter, the Sea-kale is as worthy of a place in every cottage garden as Cabbages and Brussels Sprouts.

Where vegetables are at all scarce, allow me again to recommend placing a score or two of Swedish Turnips with their tops uncut in any dark place, with a temperature from 50° to 60°. The tops, if cut when 6 to 7 inches long, make a delicious yellowish dish, which many prefer to Sea-kale. The blanching takes away much of the natural acridity of the Turnip top, leaving just enough to make it agreeable.

FRUIT DEPARTMENT.

Looked over our fruit room, which is new and a little damp. Pears have not kept so well as Apples. We have open slatted or railed shelves, the slats 3 inches wide, with three-quarters of an inch between them, and a boarded floor.

Grapes.—Picked a few berries from late Grapes, which showed no signs of damping, until we were obliged to place a lot of plants on the stages. Set the first division of vinery in action, and placed shrubs and scarlet Geraniums showing bloom for cutting on the stage, and bulbs coming on in front. Began to use the Peach house, the floor of which is as yet filled with Geraniums in boxes, filling the shelves from a pit with Strawberries in pots, each plant having about 1½ inch square of space, until they are thinned. Put more Strawberries where they would have enough bottom heat to bring them on gently, but not to entice the roots downwards. A small wedge not much larger than an ordinary tally, inserted between the sash and the rafter, will keep sashes safe in windy weather.

ORNAMENTAL DEPARTMENT.

Our chief work has been

Moving and replanting large trees, though the weather was anything but suitable for the work. The trees had received no previous preparation, and therefore required much root-tracing. I would tell those contemplating such work that unless provided with very efficient machinery, the moving of fine trees with boles ranging from 12 to 15 and 18 inches in diameter will but rarely be very satisfactory, as for several years they merely exist before beginning to grow freely again. With younger trees, the diameter of whose bole ranges from 4 to 8 inches, the work is comparatively light, and after the first year the trees will soon get over the check and grow away freely. Without previous preparation much of the success will depend on the careful tracing of the roots and the packing of them well. The soil is just rather wet for packing, and it is as well in such changeable weather not to have the holes made long before they are wanted.

Damp in Cold Pits and Frames.—We gave air freely at the top and bottom of pits and frames which contained Geraniums, to keep the plants from damping, but we would like better to have them in a little fire heat if that were possible. Many thanks to Mr. Peach for his excellent article and plan of house at page 16. It will confirm what we have all along stated as to the superiority of a little house, however heated, over a pit into which you cannot gain admission. Taking the comfort into consideration, the little extra expense for fuel in comparison with the covering necessary for pits and frames will be as nothing. The looseness of the grooves will contribute greatly to the safety of the glass when put closely edge to edge. When put closely edge to edge and held firm at the sides, there is risk of breakage from expansion.

Watering.—All pot plants, especially in low temperatures, must be watered with judgment, but bulbs throwing-up their flower-stalks will want a good supply. Primulas, Cinerarias, and Calceolarias must not be kept dry. These, all softwooded plants in general, and hardwooded plants in particular, should never have any water poured close to or against the stem, especially in such close wet weather. Thousands of promising Chinese Primroses, and also Cyclamens, are damped and rotted-off by allowing the collar or stem always to be wet. In watering it is best to sail the top of the pot by pouring the water on a crock or shell close to the side of the pot. It is easy to hold the pot in one hand and a large crock in the

other. Air in a mixed house should be most freely given opposite the hardiest and most backward blooming plants. In a mixed house, therefore, it is well to place the plants in groups, which will require similar attention. Potting has chiefly been confined to Pelargoniums, Ferns, Gloxinias, and picking-out some Achimenes and Gesneras to come in early. Placed some Azaleas where they would be forced gently into bloom. Shrubs taken up and potted for forcing, will be much helped if the pots are plunged in the open air in a mild hotbed, so as to root afresh before the heads receive much heat.—R. F.

TRADE CATALOGUES RECEIVED.

Downie, Laird, & Laing, 17, South Frederick Street, Edinburgh, and Stanstead Park, Forest Hill, London, S.E.—*Descriptive Catalogue of Garden, Flower, and Agricultural Seeds, &c.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen Garden, Flower Garden, and Farm.*

Dick Radclyffe & Co., 129, High Holborn, London, W.C.—*Spring Catalogue of Vegetable, Agricultural, and Flower Seeds, &c.*

Butler & McCulloch, Covent Garden Market, London, W.C.—*Spring Catalogue of Seeds for the Kitchen Garden and Flower Garden, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

SEEDLING GLOXINIAS (*T. C. Brigg*).—They are very good. You had better send specimens to the Floral Committee of the Royal Horticultural Society. It will meet on the 17th.

GRAPES SHANKED (*H. G., Chichester*).—The bunch sent is totally shanked, and it is evident from your query that the shanking arises from a deficient supply of sap, and that deficiency is caused by the inside border being kept dry. When the Vines are about to be started, thoroughly soak the border with tepid very weak liquid manure, mulch the surface, and water moderately once a-week during the season of growth. Treat the Peach border similarly.

SELECT FRUITS (*J. L.*).—These will all "come in one after the other." *Twelve Pears.*—Citron des Carmes, Jargonelle, Beurré d'Amanlis, Louise Bonne of Jersey, Seckle, Van Mons Léon Leclerc, Doyenné du Comice, Beurré Bosc, Forelle, Winter Nelis, Glou Morceau, Bergamotte Esperen. *Twelve Apples for Dessert.*—Early Harvest, Devonshire Quarrenden, Kerry Pippin, Fearn's Pippin, Yellow Ingestrie, Golden Winter Pearmain, Cox's Orange Pippin, Golden Reinette, Adams's Pearmain, Cockle Pippin, Manningtoo's Pearmain, Sturmer Pippin. *Twelve Kitchen Apples.*—Keswick Codlin, Stirling Castle, Lord Suffield, Cox's Pomona, Cellini, Bedfordshire Foundling, Emperor Alexander, Mere de Menage, Warner's King, Yorkshire Greening, Alfriston, Norfolk Beefing. *Twelve Peaches.*—Early Rivers, Early Beatrice, Early Grosse Mignonne, Dr. Hogg, Early York, Grosse Mignonne, Royal George, Noblesse, Bellegarde, Barrington, Walburton Admirable, Lord Palmerston.

BIDENS ATROPURPUREA (*Goodness*).—Botanists have no plant so named, but some nurserymen call Cosmos diversifolius *var.* atrosanguineus by that name. It is not a glaring blunder, for Bidens, Coreopsis, and Cosmos are allies. Coreopsis coronata is a native of Texas, whence it was sent by Mr. Drummond the Royal Horticultural Society's collector, in 1835. Its specific name, *coronata*, refers to the circle of crimson splashes on the petals, which have the appearance of a coronet.

LABELLING (*J. J.*).—It is not usual to prefix the name of the kind of fruit Brushing the bark with a strong brine made by dissolving common salt in water will remove the green moss.

WHERE TO MOVE TO (*A Berkshireman*).—The query related exclusively to a gardener's employment. But we cannot aid you. Anywhere within forty miles of London and near a railway station would suit your purpose.

DEFECTIVE FLUE-HEATING.—"I cannot yet understand how to make my flue fire burn for any length of time. I suspect that mine is radically wrong. The flue runs the length of the house, and returns to the same spot for the chimney. The fireplace is outside the house, and has nothing to separate it from the flue, so that the fuel could be driven the whole length of the house if one thought proper. Then they talk of the ashpit doors. The fuel rests upon bars, with nothing underneath them, entirely open to the air. As it is, the fire rages furiously when the door is open, and lasts for a few hours. If the door be left open the fire goes out."—H. L. W."

[There is no doubt that your furnace for the flue is wrongly constructed. All you have to do is to lower the furnace, so that the fires may be from 18 to 24 inches below the level of the bottom of the flue. Have an ashpit, say at least a foot in depth, beneath the bars, and have a close-fitting door to it, with a ventilator in it. Leave the ashpit door open until the fire is established, and then keep the furnace door shut, and allow just as much air at the ashpit door as will support slow combustion. Of course until you get the heat up, a good deal of air must be left on the ashpit door. When the heat is up a slow combustion will be sufficient, and that must be regulated from the ashpit door.]

FENN'S ONWARD POTATO (*Potato-fancier*).—It requires generous cultivation and is especially suitable for garden ground. Apply to the Messrs. Veitch, Royal Exotic Nursery, King's Road, Chelsea, S.W.

PLANTS NOT THRIVING IN CONSERVATORY (*Beechwood*). — We can only account for the plants doing so indifferently, from the house not being adapted, for flowering plants in winter. We do not wonder at the Camellias casting their buds, Chrysanthemums half expanded when put in never fully opening, and Cineraria flower-buds blind. The house is glazed with thick frosted glass, than which nothing looks so pretty, and than which nothing is more unsuitable for flowering, nor, indeed, any kind of plants in winter, and in summer only suitable for flowerless plants, or those requiring shade. Rough plate, or that ground on one side, is sufficient to diffuse the sun's rays; frosted glass prevents the passage of light to too great an extent. The fault we should say is in the gas-pipe, from which we think there must be an escape. The water you allude to will not injure the plants; at least our supply is from iron pipes.

CROTON PICTUM AND VARIEGATUM LOSING THEIR LEAVES (*An Inquirer*). —The cause of leaves falling from the young growths is the imperfect ripening of the wood, due to a deficiency of heat and light; and considering the amount of light and heat the plants have been exposed to, we think they have been too copiously watered. Crotons require an abundance of light and no shade in summer in order to colour well. Keep them dry from the present time up to March, not allowing the leaves to fall from want of water, and then you may cut them back if straggling, keeping them rather dry in a bottom heat of from 75° to 80°, and not potting until the plant has broken, then repot. Keep Allamanda nobilis dry, and cut back to firm wood in February, repotting after it begins to grow.

PLACING HYACINTHS IN HEAT (*An Old Subscriber*).—The Hyacinths which you have had out of doors, covered two months with coal ashes, we should remove at once, and place near the glass in a house with a temperature of from 40° to 45° at night, and 45° to 50° by day from fire heat. A stove with a temperature between 65° and 70° would bring them forward too rapidly, but on a shelf near the glass they would not be so liable to become drawn, and might flower fairly, but we believe they would only be moderately well. They would flower much better without heat if the roots were merely protected from frost. Syringing with very hot water will not kill thrips, and if warmer than 140° it will injure the Azaleas. Syringe them with tobacco water, made by pouring half a gallon of boiling water on an ounce of the strongest shag tobacco. Cover over closely, let the liquid stand until cool, then strain, and syringe the plants on the under sides of the leaves. Instead of using this you may dilute the tobacco water of the shops with six times its volume of water, and syringe the plants.

CALLAS NOT FLOWERING (*Paganini*).—We are not surprised at the plants not meeting your wishes, for you expect too much. They will not flower again until from March to May, and we should now keep them rather dry, not allow the foliage to suffer, and place them in a temperature of not more than 45° to 50° for six weeks; then encourage them with plenty of water, and a temperature of from 50° to 55°, and we think you will have as fine a spring as you appear to have had an autumn bloom.

USES OF SMALL FRAMES (*C. L. D.*).—Your frames 3 feet wide, 2 feet 6 inches high at back, and 1 foot 6 inches in front, with glass tops, fronts, and ends, the backs and bottoms of wood, will be useful for many purposes; but we do not see any necessity for a glass front or glass end. Wood would be better, as it is not so liable to be damaged as glass, and there is no necessity for a bottom of any kind. Such a frame would be useful for placing over a gentle hotbed intended for raising half-hardy annuals as Tender Annuals, for bedding plants previous to planting-out, for placing over for hardening-off bedding plants in winter, or for anything needing protection; and in summer you might grow Cucumbers or Melons on a gentle hotbed, putting out a plant at every 6 feet of length. Achapesnorrischer Melon is a good sort, to be sown in a hotbed, planted out on a little bottom heat, and to be covered with glass at least up to July. In every respect it requires the treatment of ridge Cucumbers and is better of glass, which may be raised so as to allow the Vines to come under it, elevating the frame or glass at the corners, which will protect or throw off heavy rains from the collar of the plants. They are impatient of wet on their stems. The flavour is good.

EVERGREENS UNDER LIME TREES (*Inquirer*).—As the Lime trees are so very close together, we fear the ground will be so matted with roots as to prevent any undergrowth. The Lesser Periwinkle (Vinca minor) would give a close green covering, and the common Ivy (Hedera Helix) will grow where scarcely anything else will. Common Laurel pegged down might answer, and the Aucuba will grow where Laurels fail. Butchers' Broom and Spurge Laurel are also good.

PERIOD OF RESTING VINES (*J. H. Jones*).—From the time the leaves fall until the Vines start into growth, two months should be allowed. Prune as soon as the leaves are off. They are the better of three months' rest.

MUSCADINE GRAPES NOT RIPENING—APPLYING SALT (*H. Foy*).—The most likely cause of the fruit not ripening is the shade of the Black Hamburgh; it is useless to try to grow Vines under Vines. Give them equal advantages, and the Muscadine will ripen its fruit as well as the Hamburgh. Twelve bunches are too many for a Vine just commencing bearing. Ten bushels of salt per acre will be a sufficient dressing. This will be exactly two quarts per rod. It will be of no use now, except to save the plants from frost, and we do not advise it to be applied until March.

TAR ON HOT-WATER PIPES (*A Constant Reader*).—If your hot-water pipes are painted with tar, your only remedy is to take them out, make up a fire of brushwood, and burn the tar off. The scum on the rain-water tank is undoubtedly owing to the gas tar. No plant will thrive in the house as long as the tar remains on the heated pipes. If the pipes have been coated with a mixture of tar or varnish and oil paint, you may dip cloths in a solution of soft soap, 8 ozs. to the gallon, and wrap them round the pipes for forty-eight hours, keeping them saturated with the solution, and the paint may peel off; but we think your only remedy will be burning it off.

ERRATUM.—At page 16, sixth line from the end of "EXPERTO CREDE'S" remarks on the Gladiolus, for "improved" read *unproved new*.

OVER-LUXURIANT REINE HORTENSE CHERRY (*E. P.*).—As your tree blossoms freely it would do it no good to lift it. Keep the tree nailed to the wall in the usual manner, do all the training and thinning of the young shoots in the usual manner, do all the training and thinning of the young shoots in summer, and destroy aphides by frequent syringing. Reine Hortense is a shy bearer. If it will not succeed with you, others of the Duke class will,

such as May Duke or Archduke. In the Bigarreau and Heart class the two following are always to be depended upon—Black Tartarian and Elton.

Asparagus Bed Making (*An Amateur Gardener*).—The plants you have saved will not be suitable for a new bed, but you may force them, directions for which were given by Mr. Record a few weeks ago in this Journal. The ground where you intend to make the bed should be trenched not less than 3 feet deep, if it will admit of that, and a 3-inch layer of dung placed between every layer of soil. If the soil be heavy put in plenty of sand, and before turning on the next layer mix up the manure and sand with the soil. In this way proceed to the bottom of the soil, taking care not to bring up more than a few inches of subsoil. The earlier this is done the better, so as to let it have frost. For a single bed a width of 7 feet should be trenched to admit of 4 feet for bed and 18-inch alley on each side. In March place on a 3 to 6-inch coating of well-decayed manure, with an inch of sharp sand—sea sand if possible—and fork the ground over twice to mix the dung and sand thoroughly with the surface soil. Leave it until the early part of April, and then put in three rows of plants—two outside ones 9 inches from the sides of the bed, and one row in the centre. Take out a trench as in planting Box edgings, lay the roots against the side 1 foot apart, with their crowns level with the surface, and fill up the trench neatly. When all are planted cover up 1 to 1½ inch deep with soil from the alleys. The plants should not be older than two years, but we prefer one-year-old plants. After May water as much as you like up to September, and as often as you can with liquid manure.

Habrothamnus elegans (*Idem*).—It is a greenhouse plant, and would not succeed as a climber against a west wall in an eastern county. It is a native of Mexico.

Cucumber Culture (*M. H. B. L.*).—You must at least have a house with a temperature of from 50° to 55° at six o'clock in the morning, and capable of being raised to 10° or 15° more during the daytime, to succeed in growing Cucumbers in winter. A night temperature, ranging from 65° to 70°, with an increase usually of from 5° to 10° in the day, but from 15° to 20° in bright weather, is also essential. You may, however, begin to raise the daily temperature, by means of a hotbed, as early as the beginning of March, if you feel so inclined. Telegraph, Long Gun, and Blue Gown are all good Cucumbers, but we would select more particularly the first of these, Cox's Volunteer, Marquis of Lorne, and Master's Prolific, an early sort.

Starting Vines in Pots (*Idem*).—Weak Vines raised from eyes last year, and cut back to the second eye, should be placed in a heat of 50° to 65°, and left there until June, when they may be removed to the cool vinery.

Camellias Casting Buds (*Idem*).—Let the plants remain in the house with a temperature of about 45° until the growth is complete and the buds set; then remove them to a cool house. If they, as we think, need potting, the roots being evidently in an unhealthy state, do it at the early part of March. (*E. M. M.*).—We do not attribute this to be due to the change of temperature in consequence of the existence of a few broken squares, but rather to the condition of the roots. The small insects are most likely mites, and are often plentiful in a soil containing an excess of decaying vegetable matter. Repot the plants immediately after flowering or early in March, carefully picking out as much of the old soil as comes away freely, so as not to injure the roots, and pot them firmly in a compost consisting of the top inch of a pasture of a light sandy loam, chopped up small. Keep the point where the root and stem join level with the rim of the pot, and drain them well.

Pine Apple Culture (*H. O.*).—The plants potted last September in 12-inch pots we would not shift into larger ones now, but as the pots are filled with roots you may remove a few of the lower leaves, top-dress them with rich compost, and place them in the Cucumber house. Here they must have light and not be far from the glass. If you can afford bottom heat all the better. The temperature will be suitable.

Vine Culture (*T. H. T.*).—The Vines that have been plunged for a year we should lift carefully, taking up all the roots that have extended beyond the pots, and then by breaking the pots disentangle the roots, and lay them out in planting. You may do this when they have begun to grow, to the extent of an inch or two. To have Grapes early in July the Vines should be started in the second week in January. A great deal depends, however, on the kinds. Muscats will be three weeks or a month later than Hamburghs. Grapes will do well in a heated vinery. The wires in an orchard house, or against any wall, should be more than three-quarters of an inch from it; better if so close as only to admit of the string for tying the shoots. You would do well to dig round the Oak in March, which you contemplate moving in November.

Soil for Rhododendrons (*T. T.*).—To your deep black soil, which we think would grow Rhododendrons well with admixture, you may add in place of peat as much sandy turf as you like, leaf soil, and sand, two-thirds of the former, one-third of the second, and a sixth of the latter. This is a capital soil for them, and a fourth part of old cow dung or well-rotted hotbed manure might be added with advantage.

Material for Protecting Fruit Trees (*Black Edge*).—Of the materials you name for protecting fruit-tree blossom from frost, we prefer tiffany. The protection is not a needless expense, but very often results in securing a crop By all means use the protection you describe, taking care to keep it from brushing against the blossoms, and making safe from wind. Put it on when the blossoms are expanding, and remove it in all mild weather, using it only in frosty weather. 2. The Scarlet and Pink Thorns attacked with blight and caterpillars will not communicate the pests to other trees, but you should syringe them just before coming into flower, and again afterwards, with a solution of soft soap, 2 ozs. to the gallon. 3. We do not know of anything that, sprinkled around shrubs, will keep dogs from them, and we think your only remedy is to enclose with wire netting. 4. By having boxes made as you propose, draining them well, and filling them with soil, you would succeed in growing climbers against your house. If you had a width 2 or 3 feet there would be no necessity for changing the soil every year, but merely to remove the surface soil, and top-dress with rich soil. The main difficulty would be in keeping the frost from the roots in winter, but that difficulty you will, no doubt, overcome.

Larkfield Rival Pelargonium, &c. (*A Reader*).—The plants you mention can be obtained of any of the chief florists and seedsmen who advertise in our columns.

Names of Plants (*Alban Goodman*).—Myrsiphyllum asparagoides, native of South Africa, and a plant we hold in high favour. (*W. B.*).—1, Sida myosorensis, a generally-distributed weed in the western peninsula of India; 2, Polystichum Richardsii; 3, Very young, in all probability a Diplazium, most likely to be *D. japonicum*.

POULTRY, BEE, AND PIGEON CHRONICLE.

BRISTOL POULTRY SHOW.

In spite of the prohibitory subscription, the Bristol Show this year just exceeded one thousand entries; but it is worthy of remark that the number of exhibitors fell off materially, so that the amount gained was by no means what had been anticipated. As usual the birds were shown in single tier, which gives this Show a great advantage over even the Crystal Palace as regards seeing and judging the birds. We regret to say that again bad weather interfered with the attendance, and it is only fair to state, in reply to some of the glowing calculations which have been made, that the receipts at the doors are always considerably under £100. Last year they were about £70, and it is this unaccountable apathy of the general public which causes the Committee such embarrassment.

Dorkings.—Cockerels were rather poor on the whole, and we regret to say that in our opinion the first-prize was a case of deception, being an old bird; and we believe this was the judgment of all present. We can only say the spurs were perfectly hard and perfectly sharp, and there was an amount of white rarely seen in a chicken's tail. The head also showed evidence of age. Pullets were a fair average, but there were no birds of marked excellence save the first-prize pen. The second-prize pen contained a "very early" chicken. Cocks and hens were better classes, and the first-prize cock an enormous bird, which fairly beat Mr. Martin's Rose-comb. The hens formed the best Dorking class seen this season, and we are not sure we should not call the cup pair the best pen in the Show. Nearly every pen in this class was mentioned. Silver-Greys were very poor, the first prize in cocks being withheld, and no commendations given in either class. White cocks were good in shape, but all very yellow; the hens, on the contrary, were very fine though few, and the winning pen was unusually so.

Cochins.—There was some difference of judgment about the first and second-prize Buff cockerels, the second being the Palace cup-winner, which has left the Stoke Park yard. It was a nice point, and we believe the Judges were in some doubt. The first bird was rather the best in feet, wings, and perhaps colour generally; the second in size and shape, but decidedly gone off in condition, and he ought not to have been shown. Third came a good bird too. When we say only four others were named it will be seen the class was not of startling excellence. In pullets, we thought the first-prize a mistake, and that the second should have held that position, giving the second to the cup Palace pair, which were nearly as good as ever, though now only highly commended. Among the old cocks were several rare birds, but nearly all were somewhat rough, which certainly threw out the cup-winner of last year; this bird has grown to such an enormous size that at our request he was weighed by one of the officials of the Show—he scaled 2 ozs. short of 15 lbs. Of hens we liked Mr. Taylor's second-prize pen better than his first, but all three were rather evenly matched. Partridges disappoint us more and more; the decadence is not confined to one breeder but is general, nearly all the cocks getting clumsy and round-backed. They were out of condition, which injures a bird's carriage; but we did not see a really first-rate bird in the class. Pullets and hens were better, perhaps, but far from what they used to be. White cockerels were better in colour than usual; the pullets also a nice lot, and owing to the late date more developed than at other shows. The first-prize pair were really beautiful, the old cocks yellow, as usual, the only White bird being the commmended, 212. In hens, the cup pair had one grand bird, and another very fine. Mr. Sichel's birds lost for want of a washing. Except in the colour of the cocks, it struck us Whites are improving.

Brahmas.—Cockerels were the finest collection in point of quality ever brought together. The Palace cup-winner was again to the front, and though recklessly overshown, had really improved since Edinburgh Show. Second came a very fine bird in shape and colour, but with heavy hocks. The third-prize bird was of good colour, but had no other redeeming point, and this award should have been given to the highly commended pen 242. In this class an unusually conspicuous case of plucking was properly visited by the Judges and Committee with disqualification and publication in the catalogue. Pullets also were a grand class, the Palace pen, fourth at Birmingham, being again to the front. Their fine marking was as good as ever; but the wings of both birds being displaced or "slipped" as it is termed (as they were also at the two previous shows), should, we considered, have thrown them out altogether, giving the third prize, vacant by promotion, to Mr. Arkwright's pen 238. The second prize went to the Birmingham winners.

In old cocks, Mr. Taylor's bird, which was first at Birmingham and degraded at Manchester through overshowing, was here out altogether, having quite gone off his legs. Very possibly he is ruined, and we would suggest to the Judges that they might with

benefit meet this growing evil by refusing to award prizes nearer the commencement of the poor bird's sufferings. The cup bird was fine in nearly all points; the second we did not like much; the third-prize bird very fine in head, shape, and plumage, but too long and rather white in the tail. Among the hens were several good pairs, the second perhaps the best. In Lights the cup bird was fine in shape and size, but had a badly slipped wing. Second, medium shape and size, but no colour; third rather small, but best of the three in our judgment; we considered pen 311 to be the best in the class, being beautifully marked, of fair size, and nearly perfect shape: he was not noticed, so much do people differ. Pullets were poor as usual, the cup pen clean, but bare of feather, and pen 362 must have won, as we believe they have before, but were in filthy condition. Cup cock, fine shape and size, but again no colour. Second better, and with more leg feather he must have won. The winning hens were the usual pair, which have changed hands.

Spanish were the best classes of the whole season. The cup cockerel was a beautiful bird, in first-rate condition; the third-prize bird had a fine face and comb, but a slight redundancy of earlobe, still we think he ought to have been second. The pullets were well placed, and the cup pair were the gems of the year; in fact, the whole class was the best of the Spanish collection, and a treat after the mediocre lot seen at previous shows. The first-prize cock was very fine, but we fear has joined the early-closing movement. Hens were poor, except the first two pens. The whole season seems to have been strangely against this breed.

French Fowls.—The cup cock was a grand Crêve-Cœur, and second another worthy his place, but the third was a very poor Houdan, entered by an experienced exhibitor at four guineas, and up to Friday night at least not claimed. In this class a pair of hens were sent in mistake by such a veteran exhibitor as Mr. Fowler, and were necessarily disqualified. In hens, the first and third were fine Crêve-Cœurs, the second rather middling Houdans.

Hamburghs.—The cup Gold-spangled cock was a fine old bird. The second prize went to a bird hardly matured, but in the best condition of any in the class; the third, on the contrary, was not in good feather, a circumstance which lost him at least one place. The hens were a poor class, few of the birds being good, and good matches were conspicuous by their absence, most of the prize pens having one good bird to one bad. In Silver-spangled the winning cock was very fine; none of the others perfect in the bars. The cup hens were a first-rate pair, except that one had rather a shady tail. The second-prize hens were also good; the others below par. In the next division both cups went to the Golden-pencilled, and the whole cock class was very good. The first-prize hens were a beautiful pair; those second were not perfect in tail, but superior in body markings to the third. These two classes were perhaps the best of the Hamburghs. Silvers were not so good by far, with the exception of the winning pen in each class. In Blacks Mr. Serjeantson won easily; the condition in which he shows his birds is wonderful. Throughout this group of classes the effect of the December shows was plainly seen in a fearful loss of condition compared with what many of the very same birds had exhibited previously.

Game.—In the Game classes this remark will apply even more. Many really good birds had gone quite "soft" with the repeated confinement and course of soft food they had had, and the awards were evidently chiefly guided by the handling. Black Reds were both large and good classes; and, as usual where there are so many experienced breeders, it was easier to find fault than to pick out winners, but the prizes all went to good birds. Brown Red cocks were few, two out of eight entries not being sent. This made it easy to select the pens, the few other good birds having sadly gone back. In hens no pens beyond the three were mentioned. Duckwings were also small and poor classes. The winning cock was a fine bird, but too dark in colour. The next class contained only three Pile cocks, which shared the list between them; and in hens only one bird put in an appearance, which, being a very good one, was awarded the first prize "to encourage the rest." On the whole, perhaps, the Game were the most unsatisfactory classes in the Exhibition.

Polish.—In the cock class every pen but one was highly commended, Silvers being first and third, and Gold second. In hens Mr. Adkins was first again, and a pair of Golds third. No Blacks were shown, the first time, we think, this has ever occurred at a Bristol Show.

Malays.—These were the best entries of the year, eleven cocks and sixteen hens being entered. Cocks were a fine class, Mr. Brooke being beaten at last by a young cockerel, which was at once claimed at two guineas and a half. Hens, on the contrary, were poor in quality, or rather in condition, though more numerous. Several of them showed that the owners did not know what a Malay is, being quite destitute of that peculiar shape which enables a fancier to know one even in the dark. Mr. Hollis won again, and fairly in our opinion. Some thought Mr. Brooke's bird best, but she was not in good order by any means, and the rev. gentleman's really best bird was in worse, and only highly commended.

Any Variety.—Here we were puzzled by the judging. In cocks, the first prize went to a Silky, stated by the Judges to be the best they remembered, yet absolutely destitute of feather on the legs, and much too long in the tail in our opinion. Second was a Pekin Bantam, and third a really miserable so-called Black Cochin, almost bare-legged, and exactly the shape of a leggy Brahma. A very poor Leghorn, with very short and nearly white legs, was highly commended; while a young cockerel, the finest yet sent to England, and perfect in every point, having been selected by the Treasurer of the New York Poultry Society as a standard bird for portraiture, was unnoticed. This and the following class were remarkable for two pens, stated by Mr. Moor to be a "variety of Brahma," and put in at a high figure. The colour of the pullets was a bluish pale grey or drab, rather sickly to our taste; but we heard an old lady remark she had never seen "such lovely-coloured fowls," and possibly if bred to a decent shape they might be popular. In hens, first came unusually good White Minorcas; second, the best pair of Sultans we have yet seen; and third, rather poor Black Cochins. A really good strain of the latter variety would carry all before it, but in our opinion not a single pen in either class of this variety was pure bred.

Ducks.—Aylesburies were only four entries, but all good. In Rouens a pair that would not disgrace Birmingham were first. The second-prize drake was nearly as good, but the Duck was by no means equal. The Black East Indians had a class to themselves. There were several good pairs, but Mr. Sainsbury's winners were worth the lot, both for smallness, colour, and style generally; in fact, they have never appeared in equal condition to what they here showed. The "Any variety" class contained two pairs of the Black Cayuga, new to this country, and very erroneously stated by one of the Judges to be similar to the Black Ducks so common in Lancashire. It surpasses any other large Duck in flavour, requires very little water, and has the gift of getting and keeping fat on much less food than any other Duck of its size. None of these are shared by the Lancashire breed. First and third were Mandarins and Carolinas, as usual; the third being deservedly given to a very remarkable pair of Whistling Ducks, which drew much attention by their peculiar notes. Both sexes are similar in plumage. The sides of the breast are beautifully pencilled, something like a Grouse in colour, but quite straight across the feather; back and wings something like the Rouen female, but very dull-marked; head white to one-fifth of an inch behind the eye, where the white ends in a straight perpendicular line; bill black, breast claret, and carriage like a Woodcock. The Cayugas were only commended.

Geese only showed five pens for six prizes. In the "Any variety" class, besides Embden and Toulouse, the first prize went to a fine pair of Chinese, which were firmly believed to be Swans by many of the ladies present.

Turkeys.—These were the finest ever seen at Bristol, the winning pair being fit to compete anywhere. This class contained a magnificent pure wild American cock, also sent over by Mr. Simpson, but which was unfortunately out of competition through having no partner. He only arrived from Liverpool three days before the Show, but even as he was, the splendid plumage in which the wild breed surpasses all domestic varieties attracted much notice and commendation.

Game Bantams.—In the Reds, nearly all the birds had gone more or less soft from repeated showing, but the cup pen stood grandly out, and no judge could have decided otherwise. In the "other variety" class the first-prize pen contained a beautiful young cock, with a hen far from worthy of him. Mr. Eaton's second were also a good pair, not having been shown before; but to the rest the same remark as to condition will fully apply. The Single cocks (any variety), was the treat of the Game classes. The cup bird was simply perfect: where he comes from we do not know, but he was the counterpart of Mr. Eaton's exquisite Palace Duckwing (which has changed hands for twenty guineas), and he fairly beat Mr. Eaton's own bird, winner at both the Palace and Birmingham Show, which was put third. Second was a good bird, but with a squirrel tail, and every Bantam-breeder allowed that second and third should have changed positions. But of this we are certain—that the lot were the three best Black Reds that we have ever seen together at one show.

In Black Bantams the cup went to Bristol, the pair being very fine, and in fact ten guineas were offered for them almost immediately the Show was opened. As to the other prizes, there were about four pens so nearly equal that they might have cast lots for second and third. Mr. Maynard's pen, 799, was much admired, but the hen was too gamey for a Black, and her dark gipsy face, together with her shape, might cause suspicion of a Brown Red cross. The cup Whites were beautiful birds. In Sebrights Mr. Leno swept the whole list, as usual of late; but we must say, looking at these birds year by year, we do not think they are improving.

Mr. Teebay judged the Game, Hamburghs, and Game Bantams; Messrs. Hewitt and Teebay the Brahmas (both varieties);

the Rev. G. Hodson all other Bantams, French Fowls, and we think the Any variety class; Mr. Hewitt, Polish, Geese, Ducks, and Turkeys; and we believe Messrs. Hewitt and Hodson the rest.

DORKINGS (Coloured).—*Cockerel.*—1, W. Arkwright, Sutton Scarsdale, Chesterfield. 2 and 3, L. Patton, Hillmore, Taunton. *hc*, E. Burton, Truro; A. Darby, Brid gnorth; J. B. Saunders, Taunton: R. W. JUDGES.—*Poultry :* Messrs. W. Smith, Wishaw; Tuille, Chapelhall; Purdie, Abington; Logan, Carnwarth. *Pigeons :* Messrs. D. K. Mackay, Glasgow; A. Young, Carluke. *Canaries :* Messrs. G. Grant, Glasgow; J. Brown, Pollockshaws; J. Lindsay, Hamilton; J. Rennie, Wishaw.

CORK AND SOUTH OF IRELAND POULTRY SHOW.

THE twelfth annual Exhibition of the South of Ireland poultry, Pigeon, and Cage Bird Associatiou was open ed on the 3rd inst., in the Assembly Rooms, South Mall, Cork. The Show was larger than usual, and the quality of the birds far superior to any specimens hitherto exhibited. The Judge, Mr. Jones, stated that he had not seen better poultry and Pigeons at any of the shows which he had judged in England lately.

A small number of *Brahma Pootras* were exhibited, but of excellent quality. The *Cochin* fowls were an excellent class. The *Crève-Cœurs* attracted much attention, and the Spangled and Pencilled *Hamburghs* were particularly good, the prize-winners in both classes being birds of especial merit. There was a small entry of *Polish* fowl, but the quality was very good. The show of *Turkeys* was not as large as was expected. Notwithstanding the inducements of class prizes and,the offer of a silver cnp by Mr. Wilson, Victoria Hotel, the entries in this class were fewer than in former years. The collection of *Ducks* was large and the quality good. A pair of Black *Swans* were exhibited by Colonel Stawell.

In the *Pigeon* department the Pouters were especially good; and the Carriers, though small in number, were of excellent quality. The Barbs exhibited were as usual very good. Mr. Dowling has not been as successful as usual, as his best birds were away at Manchester, where they took the first prize, and were sold for fifteen guineas the pair. The Owls were far better than any before exhibited, and the prize pair were perfect gems in their way. The Trumpeters were of a class superior to any ever before exhibited in Cork. The entries in Jacobins, which were an extremely good class, were unusually large, and gave the Judge considerable trouble in deciding which was to carry off the blue ribbon. The Nuns were small in entry, but of very good quality. The Turbits were largely represented and were specially good, nearly every bird in the class being commended. The Magpies were far better than any previously shown, but the Tumblers were few in number, and those shown but middling. In the Variety class the first prize was won by a magnificent pair of White Dragoons; and the Society's silver medal for the winner of the greatest number of prizes was awarded to one of the local exhibitors, Mr. John Dowling, of Blackrock.

The show of *Cage Birds* was remarkably large and good. There was a magnificent collection of Canaries. The Bullfinches, Goldfinches, and Linnets were tolerably good, and these classes seem to be improving. The Blackbirds, Thrushes, and Larks were of a fair class, and a good number were exhibited. In the Variety class a very handsome pair of Cockateels took the first prize, and a cage of ornamental birds were, on account of their extreme beauty, a principal attraction for the ladies.

In consequence of an incorrect entry, Mr. Perrin was disqualified in the class for Single Game Cocks, and the cnp was awarded to Mr. Cramer, the second prize to Mr. Ducrow, and the medal for the greatest number of prizes in poultry to Mr. J. C. Cooper.

SPANISH.—1, W. H. & G. A. Perrin, Loughlinstown. 2, J. C. Cooper, Limerick. *c*, T. A. Houd, Tullygarden; S. Mowbray, Mountrath; W. H. & G. A. Perrin.
DORKINGS (Grey).—1, J. C. Cooper. 2, S. Mowbray. c, Capt. Downman, Kingstown. *Chickens.*—1, J. C. Cooper. 2, S. Mowbray. *hc*, T. O'Grady, Rochestown. *c*, Capt. Downman; T. O'Grady (2). *Coloured.*—1, W. H. and Queenstown. *Chickens.*—1, S. Mowbray. *White or other.*—1, Mrs. Hay (White). 2, J. Perry, Cork. *c*, Countess of Bandon, Castle Bernard, Bandon.
BRAHMAS.—*Dark.*—1, Lady A. Lloyd, Villierstown. 2, J. C. Cooper. *Chickens.*—1, J. C. Cooper. 2, L. F. Perrin, Loughlinstown. *c*, Lady A. Lloyd. *Light.*—1, 2, and *c*, Mrs. Hay. *hc*, Capt. Downman.
COCHINS.—*Buff or Cinnaman.*—1 and *c*, W. H. & G. A. Perrin (Buff). 2, Mrs. Hay. *hc*, Capt. Downman (Buff). *Chickens.*—1, W. H. & G. A. Perrin (Buff). 2, Mrs. Hay (Buff). *hc*, Capt. Downman (Buff); Mrs. Hay (Buff). *White or Partridge.*—1, W. H. and G. A. Perrin (Partridge). 2, J. K. Milluer, Dublin. *hc*, Mrs. Hay (Partridge.) *Any other colour.*—1, Miss Quin, Innishannon. 2, Col. Hassard, Kildare (White)
HOUDANS.—1, J. C. Cooper. 2, Viscountess Doneraile, Doneraile.
CRÈVE-CŒUR OR LA FLÈCHE.—1, J. C. Cooper. 2 and *hc*, Viscountess Doneraile (Crève-Cœur and La Flèche). *c*, Mrs. Dring, Cork (Crève-Cœur); E. J. Poer, Limerick (Crève-Cœur).
HAMBURGHS.—*Spangled.*—1, W. H. & G. A. Perrin (Silver). 2, Countess of Bandon (Silver). *Pencilled.*—1, S. Mowbray (Golden). 2, R. P. Williams, Clontarf.
POLISH.—1, W. H. & G. A. Perrin. 2, R. P. Williams. *c*, J. K. Milluer.
GAME.—*Black Red.*—1, W. H. & G. A. Perrin. 2 and *hc*, M. C. Cramer, Kinsale. *c*, P. Ducrow, Douglas; T. O'Grady. *Brown Red.*—1, M. C. Cramer. 2, W. H. and G. A. Perrin. *Any other colour.*—1 and 2, W. H. & G. A. Perrin. *c*, M. C. Cramer (Duckwing); E. J. Poer (Duckwing.)
GAME BANTAMS (Black Red).—Col. Hassard. 2, E. J. Poer. *c*, T. O'Grady; G. H. Bull, Cork; W. H. & G. A. Perrin (2).

GEESE.—1, J. C. Cooper. 2, Mrs. V. Tomkins (Danubian).
DUCKS.—*Rouen.*—1, R. P. Williams. '2, S. Mowbray. *hc*, J. C. Cooper. *c*, W. H. Massy, Macroom. *Aylesbury.*—1, S. Mowbray. 2, R. P. Williams. *hc*, J. C. Cooper. *c*, N. E. Wallace, Dublin.
WATERFOWL (Any other variety).—1, R. P. Williams (Bahama Ducks). 2, Col. W. St. L. A. Stawell (Black Swans). *c*, T. Babington, Cork (Muscovy Ducks).
ANY OTHER VARIETY.—1, Col. W. St. L. A. Stawell (Golden Pheasants). 2, Master C. H. Purcell, Mallow (Sebright Bantams). *hc*, Mrs. Dring (Black Hamburghs). *c*, Countess of Bandon (Japanese Bantams); S. Mowbray (Scotch Greys); Col. W. St. L. A. Stawell (Common Pheasants).
SELLING CLASS.—1, Mrs. Hay (Buff Cochins). 2, S. Mowbray (Dorkings). 3, J. K. Milner. *hc*, J. Perry (Buff Cochins); W. H. & G. A. Perrin; Mrs. Hay (Coloured Dorkings); H. L. Tivy, sen., Cork (Black Spanish). c, Lady A. Lloyd (Light Brahmas); J. C. Cooper; Col. Hassard (Black Red Game Bantams); P. Ducrow (Black Red Game); Mrs. M. E. Hughes, Rathcormack (Spangled Hamburgh); J. Perry (Spanish).
GAME (Not Bantam).—*Cock.*—1 and Cup, M. C. Cramer. 2 and *vhc*, P. Ducrow. *hc* and *c*, M. C. Cramer (Black Red).
TURKEYS.—*Poults.*—1 and Cup, J. C. Cooper. 2, Countess of Bandon.
DUCKLINGS (Any Breed).—1 and Cup, J. C. Cooper. 2, Mrs Taaffe, Plumket.
Medal for greatest number of points in poultry, Mr. J. C. Cooper.

PIGEONS.

POUTERS.—*Cocks.*—1 and 2, F. W. Zurhorst. *hc*, J. Dowling; J. Lloyd, Cork. *c*, J. Lloyd; H. Perrott, Cork. *Hens.*—1, J. H. Perrott. 2, F. W. Zurhorst. *c*, J. Dowling; J. Lloyd; J. K. Milluer.
CARRIERS.—*Cocks.*—1, J. Jeffries, Cork. 2, R. W. Smith, Cabir. *hc*, G. A. Wherland, Cork. *c*, G. A. Wherland; R. W. Smith. *Hens.*—1, J. Dowling. 2, G. A. Wherland.
BARBS.—*Black or Dun.*—1, G. A. Wherland. 2, J. Dowling. *hc*, J. Lloyd. *c*, J. Dowling; J. Lloyd. *Any other colour.*—1, G. A. Wherland (Yellow). 2 and *hc*, J. Dowling. *c*, W. H Bennett (Yellow.)
OWLS.—1, J. Dowling. 2, H. L. Tivy. *hc*, J. Jeffries; F. W. Zurhorst. *c*, W. J Rumley, Middleton (Blue).
TRUMPETERS.—1, J. H. Perrott. 2, *hc*, and *c*, H. L. Tivy.
JACOBINS.—1, W. R. Smith (Red). 2, T. O'Grady (White). *c*, J. Dowling; J. K. Milner; F. W. Zorhorst.
FANTAILS.—1, T. Martin, Kildare. 2, J. Dowling.
NUNS.—1 and 2, J. Dowling.
TURBITS.—1, W. J. Rumley. 2, H. L. Tivy. *c*, T. Martin; W. J. Rumley (2); J. M'Donnell; J. Dowling; J. K. Milluer.
MAGPIES.—1, L. F. Perrin. 2, J. M'Donnell. *c*, T. O'Grady; F. W. Zurhorst.
TUMBLERS.—1, J. Perry. 2, J. Dowling.
ANY OTHER VARIETY.—1, J. Dowling (Dragoons). 2, J. M'Donnell (White Barred Teek). *hc*, F. W. Zurhorst (Antwerps). *c*, J. K. Milluer.
SELLING CLASS.—1 and 3, J. Dowling. 2 and *hc*, R. W. Smith (Spots). *c*, J. M'Donnell; J. Dowling (2); R. Evans, jun., Cork (Blue Owls); J. Perry (Barbs); R. W. Smith (Yellow Jacobins).
CARRIERS.—1, 2, and *vhc*, G. A. Wherland. *c*, J. Dowling; J. Jeffries.
BARBS.—Medal, J. Jeffries. *hc*, W. J. Rumley; J. R. Wherland; J. Dowling. *c*, R. W. Smith.
TRUMPETERS.—Cup, J. H. Perrott.
JACOBINS (Black, Red, or Yellow).—Medal, R. W. Smith (Red). *hc*, F. W Zorhorst. *c*, W. J. Rumley (Yellow).
Medal, for greatest number of points in Pigeons, J. Dowling.

CAGE BIRDS.

CANARIES.—1 and *c*, T. Babington. 2, D. Ryan, Gardener's Hill. *hc*, D. Ryan; J. Penrose, Cork; A. Allan.
BULLFINCHES.—1, J. Dowling, jun.
GOLDFINCHES.—1, W. E. O'Hea, Cork. 2, D. Higgins, Cork. *hc*, D. Higgins; W. Stenson, Cork. *c*, J. Dowling, jun.
LINNETS.—1, E. Burke, Blackrock. 2, J. Dowling, jun. *hc*, J. A. Ross; W. E. O'Hea. *c*, Cork (2).
MULES.—1 and 2, R. Bull, Cork. *hc*, R. Jones, Cork; W. E. O'Hea; C. O'Brien, Cork.
BLACKBIRDS.—1, J. A. Ross. 2, P. Keating.
THRUSHES.—1, R. Jones. 2, W. Waters, Monkstown. *hc*, D. Higgins; J. Hobson, Cork; J. A. Ross. *c*, D. Connolly, Cork.
LARKS.—1, R Jones. 2 and *hc*, D. Higgins. *c*, J. Dowling, jun.; J. A. Ross.
ANY OTHER VARIETY.—1, D. A. Bayley, Cork (Cockateels). 2, J. Hosford (Cardinals). *hc*, Mr. M'Carthy (Starling); D. A. Bayley (African Parakeet).

JUDGES.—*Poultry and Pigeons :* Mr. P. H. Jones, Fulham, London. *Cage Birds :* Mr. T. O'Grady, The Court, Rochestown, Cork.

KIRKCALDY POULTRY SHOW.

THE twenty-first annual Show of the Fife and Kinross Ornithological Society was held in the Corn Exchange, Kirkcaldy, on the 1st and 2nd inst. This Society was at first established to encourage the cultivation of cage birds only, but for some time has included in its schedules poultry and Pigeons. On this occasion, although great numbers of shows were held simultaneously, it was a great success.

In the five *Game* classes there were forty-seven entries, many of the birds being of high quality and shown in fine order. The *Dorkings*, though not so numerous, were exceedingly good in colour (mostly of the Dark variety), and sound in feet; and the cup was awarded to a pair of hens. The *Cochins* were not quite equal to the Dorkings, but the *Brahmas* were very good. In the cock class the first prize was awarded to a well-developed cockerel, and the second to an adult bird. The cup was won by a capital pair of hens. Although a cup was offered for *Spanish*

the entries were small and the quality not high. The cup was here also awarded to hens. The entries of *Hamburghs* were good and the birds well shown. The Pencilled in both classes were superior to the Spangled. The first-prize Golden-pencilled cock was about perfect, as also the pullets, to which the cup was deservedly awarded. *Bantams* were numerous, but the quality of the Red Game Bantam cocks was not remarkable, although the pullets of that variety were much better, and the cup for Bantams was given to them. These birds were, however, shown in bell-shaped pens with no divisions, though placed far apart. The advisability of this we question very much, for when shown in full sight of each other it is almost impossible to catch the spirited little fellows in such a state of repose as to allow of a proper decision as to the style and carriage of wing. In the next class (as also in hens), Piles were first and Duck-wings second, a pair of Wheaten pullets being third; and in the *Variety* class Silver Sebrights were first, Pekins second, and Japanese third. In the Variety class for large fowls the first were Crève-Cœurs, the second Black Hamburghs, and third Silver Polands. Of *Ducks*, to which was devoted but one class, little can be said, the quality being poor. In the *Selling Class* for cocks a Dorking was first, a Dark Brahma second, and a Guinea fowl third; and among hens Game were first, Dark Dorkings second, and Brahmas third.

Of *Pigeons* Pouters were shown in two classes, and a cup was offered for this division. The first-prize Pouter cock was White, and won the cup also, his measurements being 19½ inches in feather, 7½ in thigh, combined with a fine girth and good carriage, although he might have been cleaner. Second came a handsome Black Pied, 19 inches in feather and 7 in thigh, but not in good show. The third Blue Pied measured 19 inches and 6¾, but did not show well. Of hens the first-prize Black Pied ran closely for the cup, being 18 inches in feather, 7 inches in limb, very sound in colour, and in great show. The second-prize hen was White, 18 inches by 6¾, good in girth, and in prime order; and the third Blue Pied was 18 inches by 7, but low in condition. Singular to say, there was no competition either in Carriers or Tumblers, but the Fantails were a good class, as also the Nuns, which on minute examination proved free from trimming. Of Jacobins the first were White and the second Red, the cup for the best pen in the Show (Pouters excepted), being awarded to the first-named pair. Turbits and Owls were of but moderate quality, the latter variety attaining the first position. Barbs were good in quality, but out of condition. In the Variety class the competition was severe, Black Swallows being first, Ice Pigeons second, and White Trumpeters third.

There was an extensive show of *Canaries*, all of which were of the Scotch Fancy, and said by the Judge to be of the highest merit.

GAME.—*Cock.*—1, R. Stewart, Blair Adam. 2, A. P. Cowan, Kelty. 3, J. H. Herriot, Kirkcaldy. *hc*, J. W. Will, Errol; D. Penman, Kirkcaldy; A. Stephen, Blairgowrie. *Reds.*—1, J. Fisher, Kirkcaldy. 2, J. Allan, Inverkeithing. 3, R. Stuart. *Chickens.*—Cup, R. Stewart. 2, J. Beveridge, Kirkcaldy. 3, A. Parker, Carnbee. *hc*, W. Mitchell; J. Danskin, Kirkcaldy; D. Harley, Edinburgh; J. Wishart, Kirkcaldy. *Any other Colour.*—Cup, J. Anderson, Kirkcaldy. 2, D. Harley. 3, Blaik & Young. *Chickens.*—1, D. Harley. Cup and 2, Blaik and Young. 3, Elder & Lyall, Kirkcaldy. *hc*, J. Lyall, Kirkcaldy; J. Elder, Kirkcaldy.

DORKINGS.—*Cock.*—1, D. Anoan, Cupar. 2 and 3, T. Raines, Stirling. *hc*, Countess of Tankerville, Alnwick; Mrs. Tullis, Markinch; D. Gellatly, Meigle. *Hens.*—1, D. Gellatly. 2, T. Raines. 3, D. Anoan. *hc*, A. Haggart, Leslie. *Pullets.*—Cup, T. Raines. 2, Mrs. Tullis. 3, J. Robb, Leslie. *hc*, J. Haggart; J. Henderson, Dunfermline.

COCHIN-CHINA.—*Cock.*—1, R. Williamson, Grangemouth. 2, J. W. Will. 3, D. Gellatly. *Hens.*—1, R. Williamson. 2, Mrs. Oswald, Dunnikier. 3, Earl of Rosslyn, Dysart.

BRAHMA POOTRA.—*Cock.*—1, W. Brownlie, Kirkcaldy. 2, Lieut-Col. C. Rice-Cupar. 3, T. Raines. *hc*, Miss M. Morrison, Alloa. *c*, Countess of Tankerville. *Hens.*—Cup, T. Raines. 2, Miss M. Morrison. 3, W. Brownlie. *hc*, J. W. Morrison.

SPANISH.—*Cock.*—1, D. M'Beath, Bridge of Allan. 2, W. Leslie, Anstruther. *Hens.*—Cup, A. Shepherd. 2, W. Leslie. 3, R. Dickie, Stirling.

HAMBURGH.—*Spangled.*—*Cock.*—1, Mrs. Brown, Abercairney. 2, G. & J. Duckworth, Church. 3, J. M. Campbell. *hc*, R. Dickson. *c*, W. R. Park. *Hens.*—1, G. & J. Duckworth. 2, R. Dickson. 3, J. M. Campbell. *hc*, J. W. Will; W. R. Park. *Pencilled.*—*Cock.*—1 and 3, A. Pratt, Kirkcaldy. 2, R. Dickson. *hc*, R. Thomson, Kirkcaldy; J. Morrison, Alloa. *c*, Countess of Tankerville. *Hens.*—Cup, W. R. Park. 2, Countess of Tankerville. 3, R. Dickson. *hc*, Countess of Tankerville; A. Pratt.

GAME BANTAMS.—*Reds.*—*Cock.*—1, A. Hutchison, Falkirk. 2, J. Young, Kirkcaldy. 3, Master D. Laing, Kirkcaldy. *hc*, J. Mitchell, Perth; Miss Brownlie; J. Scott, Broughtyferry; T. Raines. *Hens.*—1, G. Todd, Sunderland. 2, J. Archibald, Berwick. 3, Master D. Laing. *hc*, Miss G. Brownlie. *c*, J. Young; T. Raines. *Any other Colour.*—*Cock.*—1, W. Scott. 2, Master D. Brownlie. 3, A. P. Cowan. *Hens.*—1, J. Archibald. 2, Master H. Brownlie. 3, Miss R. C. Frew, Sinclairstown, Kirkcaldy.

BANTAMS (Any other variety).—1, Master A. Frew. 2, T. Waddington, Fenniscowles, Blackburn. 3, J. Archibald.

ANY OTHER VARIETY.—1, W. R. Park. 2, A. Pratt (Black Hamburghs). 3, T. Waddington. *c*, A. Wylie, Johnstone (Polands); G. W. Boothby, Looth (Polands); Earl of Rosslyn (Cuckoo Dorkings).

DUCKS.—1, R. Dickie. 2, R. Lockhart, Kirkcaldy. 3, J. Grieg, Kinglassie.

SELLING CLASS.—*Cock.*—1, J. Rutherford. 2, Miss G. Morrison. 3, J. Nairn, Levad. *hc*, A. Campbell, Kirkcaldy; J. Haggart; J. Rutherford; R. B. Heggie, Kirkcaldy. *Hens.*—1, R. Stewart. 2, A. Haggart. 3, Miss G. Morrison. *hc*, A. Small, Glasgow. *c*, S. Greenwood, Lochgelly.

PIGEONS.

POUTERS.—*Cock.*—Cup and *hc*, M'Gill Skinner, Edinburgh. 2, W. B. Van Haansbergen, Newcastle. 3, J. M'Gill, Elie. *Hens.*—1, W. B. Van Haansbergen. 2, J. M'Gill. 3, M'Gill Skinner.

FANTAILS.—1, J. G. Spence. 2, A. Crosbie. 3, W. B. Van Haansbergen. *hc*, A. Lockhart (2); J. G. Spence, Broughty Ferry.

NUNS.—1, T. Waddington. 2, W. B. Van Haansbergen. 3, R. B. Heggie. *hc*, T. Lockhart.

JACOBINS.—Cup, W. B. Van Haansbergen. 2, T. Waddington. 3 and *hc*, J. G. Spence.

TURBITS OR OWLS.—1, A. Crosbie (Owls). 2, W. B. Van Haansbergen. 3, Miss B. P. Frew. *hc*, M'Gill Skinner (Owls).

BARBS.—1, W. B. Van Haansbergen. 2, T. Waddington. 3, A. G. M'Nish-Coupar Angus.

ANY OTHER VARIETY.—1, A. Crosbie, Melrose (Letz). 2, T. Waddington (Porcelains). 3, W. B. Van Haansbergen. *hc*, T. Lockhart (Dragoons); Miss R. C. Frew.

CANARIES.

SCOTCH FANCY (Yellow).—*Cock.*—1 and 3, W. Muirhead, jun., Alloa. 2, W. Jones, Kirkcaldy. *Hen.*—1, J. Bennet, Kirkcaldy. 2, W. Muirhead, jun. 3, R. Hunter.

BUFF.—*Cock.*—1 and 3, A. Pearson, Alloa. 2, J. Mullion, Perth. *Hen.*—1, W. Rutherford, Perth. 2, W. Muirhead, jun. 3, D. Duncan, Carron.

YELLOW FLECKED.—*Cock.*—1, J. Sime, Falkirk. 2, Hogg, Dunfermline. 3, G. Spence. *Hen.*—1, G. Spence. 2, R. Farmer, Glasgow. 3, C. Smith.

BUFF FLECKED.—*Cock.*—1, J. Hogg. 2, G. Spence. 3, J. Mitchell, *Hen.*—1, J. Sime. 2, W. Jones. 3, D. Kilgour, Dunfermline.

GOLDFINCH MULE (Yellow or Buff).—*Cock.*—1, W. Kirk. 2 and 3, J. Robertson.

The first eighteen classes of *Poultry* were judged by Mr. R. Teebay, Fulwood, Preston; the last nine classes, and *Pigeons*, by Mr. E. Hutton, Pudsey, Leeds; and the *Canaries* by Mr. James Robertson, Burntisland.

NORTHERN POULTRY SHOW.

THE sixth annual Exhibition of poultry and Pigeons opened at Aberdeen on the 5th inst. The entries were about equal to those of last year, but the quality of the birds, in general, superior. Year by year, as poultry-breeders gain experience, the quality is being more and more equalised, few inferior birds being now sent for exhibition. The classes were, almost without exception, well represented. *Dorkings*, *Brahmas*, and *Game* were most conspicuous. Indeed, we believe the show of Game fowls, both as regards the number of entries and quality, has never been equalled at any Aberdeen Show. *Geese* were a very good class, although not numerous. *Turkeys* and *Ducks* figured well, there being in the former class some very superior birds.

The show of *Pigeons* was scarcely so successful as that of last year, so far as numbers were concerned. The quality was, however, equally good. Some fine specimens of Carrier Pigeons attracted no little attention.

The following is the prize list:—

DORKINGS (Silver-Grey).—1, Mrs. M'Donald, Forres. 2, M. Edwards, Hilton Alloa. 3, G. Black. *hc*, W. Meff, Aberdeen. *c*, A. Divorty, Aberdeen. *Hens.*—1, Cup, and 3, W. Meff. 2, M. Edwards. *hc*, T. Raines, Stirling. *Cockerel.*—1 and 2, W. Meff. 3, T. Raines. *hc*, Miss E. Taylor, Inschmill, by Blackburn. *c*, L. Stewart, Keig, by Inschcouse; W. Meff. *Pullets.*—1, J. Mitchell, Caiesmill, Blackburn. 2, *hc*, and *c*, W. Meff. 3, Mrs. M'Donald.

DORKINGS (Coloured).—*Cock.*—1 and Cup, H. Stephenson, Tillyfour. 2, Mrs. M'Donald. 3, E. Fearon, Whitehaven. *Hens.*—1, Mrs. Morrison, Stirling. 2 and *c*, Miss Lind, Ladiefford, by Fraserburgh. 3, Miss D. Fordyce. *hc*, J. Clark, Fochabers. *Cockerel.*—1, T. Raines. 2, J. Clark. 3, W. Meff, *hc*, W. D. Fordyce. *Pullets.*—1, T. Raines. 2, H. Stephenson. 3, A. Shepherd, Meigle. *hc*, W. D. Fordyce. *c*, Mrs. Morrison.

SPANISH.—1 and 3, A. Shepherd. 2, T. Skinner. *hc*, W. Webster. *c*, T. Knowles. *Cockerel.*—1 and Cup, A. Shepherd. 2 and *hc*, P. H. M'Pherson. *c*, A. Allan, Udny. *Pullets.*—1 and 2, A. Shepherd. 3, W. Meff. *hc*, T. Skinner.

COCHIN-CHINA.—*Cock.*—1, A. Barnett, Montrose. 2, H. Stephen. 3, E. Fearon, Whitehaven. *c*, Mrs. Hendrie, Inverness. *Hens or Pullets.*—1 and Cup, W. Meff. 2, E. Fearon. 3, H. White, Airlie, Kerriemuir. *hc*, H. Stephen.

BRAHMAS.—1 and Cup, Mrs. Hunter, Tillery. 2, Dr. Wilson, Oldmeldrum. 3, J. Waddell, Aberdeen. *hc*, W. D. Fordyce; R. Brownlie, Kirkcaldy; H. White; J. Mackie, Ellon. *c*, Mrs. Keith, Aberdeen. *Hens or Pullets.*—1, T. Raines. 2, E. Fearon. 3, Mrs. Hunter. *hc*, Mrs. M'Donald. *c*, R. Brownlie.

HOUDANS.—1, J. Mackie. 2, Mrs. Main, Ferryhill Lodge, Aberdeen. 3, J. Logan, Eastshield, Carnbath. *hc*, A. Robertson, Carnoustie. *c*, M. Elphinstone, New Pitsligo. *Hens.*—1, J. Logan. 2, J. Mackie. 3, M. Elphinstone, *hc*, Mrs. Buin.

HAMBURGHS (Gold or Silver-pencilled).—*Cocks.*—1, R. Mellis, Newhills. 2, A. Sutherland, Aberdeen. 3, G. Laing, Persley, Aberdeen. *hc*, F. Campbell, Oldwhat. *c*, Mrs. Chalmers, Halyburton, by Cupar Angus; G. Campbell, Tillinahmolt, New Pitsligo. *Hens.*—1 and Cup, G. Laing, Aberdeen. 2, T. Knowles, Sclirk. 3, R. Dickson, Selkirk. *c*, P. Campbell; Miss E. Taylor, Fichnie, Kinellar, R. Dickson, Selkirk. *c*, P. Campbell; Miss E. Taylor, Fichnie, Kinellar, Blackburn.

HAMBURGHS (Gold or Silver-spangled).—*Cocks.*—1, E. Robinson, Craigcloan, Airdrie. 2, R. Dickson. 3, W. Smart, Aberdeen. *hc*, J. Thom; J. Taylor, Montrose. *c*, E. Robinson; W. Mearnes. *Hens.*—1 and 2, J. M. Campbell. 3, R. Dickson. *c*, W. Mearns.

GAME (Black-breasted Red).—*Cocks.*—1, W. Meldrum, Forfar. 2, C. Jamieson. 3, J. Thom. *hc*, J. Scott, Broughty Ferry. *Hens.*—1, J. Dick. 2, D. Harley. 3, J. Henderson. *hc* and *c*, C. Jamieson.

GAME (any other variety).—*Cocks.*—1, D. Harley. 2, J. Waddell. 3, A. Deswar, Aberdeen. *hc*, J. Logan. *c*, W. Heudry. *Hens.*—1 and Cup, W. Heudry. 2, J. Waddell. 3, D. Harley. *hc*, J. Deswar. *c*, W. Meff.

ANY OTHER VARIETY.—1, Miss D. Fordyce. 2 and *hc*, Mrs. M. Anderson. 3, J. Logan.

GAME BANTAMS.—*Cocks.*—1, G. Todd, Sunderland. 2, Miss J. M. Frew, Kirkcaldy. 3, J. Dick. *hc*, J. Scott, Broughty Ferry. *c*, A. Johnstone, Bathgate. *Hens.*—1 and Cup, T. Raines. 2, J. Dick. 3, R. Brownlie, Kirkcaldy. *hc*, A. Sutherland, Aberdeen. *c*, A. Frew.

BANTAMS.—1, Miss R. C. Frew. 2, J. Waddell, Airdrichill. 3, T. Watson, Bridge of Earn. *hc*, J. Marshall (2); A. Johnstone.

DUCKS.—*Aylesbury.*—1, S. Ford, Huntley. 2, J. Mitchell, Blackburn. 3, J. Logan. *hc*, A. Cowie. *Any other Variety.*—1 and *hc*, W. M'Knight. 2, H. Stephenson. 3, A. Valentine, Blackburn. *c*, A. Cowie.

TURKEYS.—1 and *hc*, W. Auld. 2 and 3, Mrs. D. Fordyce, Brucklay.

GEESE.—1 and 2, J. Logan. 3, H. Stephenson. *hc*, Mrs. Hunter.

SELLING CLASS.—1, E. Fearon. 2, P. H. M'Pherson. 3, W. Sowie. *hc*, H. Stephenson; W. Fraser, Aberdeen. *c*, W. D. Fordyce; W. Sowie; W. Meff.

PIGEONS.

POUTERS.—*Blue Pied.*—*Cocks.*—1 and 2, W. Meff, Aberdeen. 3, J. White, Aberdeen. *hc*, W. Hendry, Aberdeen. *Hens.*—1 and 2, W. Meff. 3, W. Hendry.

POUTERS.—*Black Pied.*—*Cocks.*—1, G. Schaschke, Aberdeen. *Hens.*—1, G. Schaschke. 2, W. Meff.

POUTERS.—*Red or Yellow Pied.*—*Cocks.*—1, J. Cowe, Aberdeen. *Hens.*—1, W. Hendry.

POUTERS.—*White.*—*Cocks.*—1, J. White. 2 and 3, W. Hendry. *Hens.*—1 and Medal, J. White. 2, G. Schaschke. 3, W. Hendry.

POUTERS.—*Any other Colour.—Cocks.*—1, F. M'Crae, Aberdeen. 2 and 3, W. Hendry. *Hens.*—1 and 2, J. Tough, Aberdeen. 3, W. Hendry. *hc*, F. M'Crae.
POUTERS.—*Any other Colour.—Cockerels.*—1 and Medal, W. Meff. 2, J. White. 3, F. M'Rae. *hc*, J. White. *Pullets.*—1, W. Meff. 2, J. White. 3, F. M'Rae.
CARRIER.—*Cocks.*—1, 3, and Medal, G. Schaschke. 2, W. Hendry. *Hens.*—1 and 2, G. Schaschke.
TUMBLERS.—*Short-faced.*—1, J. White. *Common.*—1, F. M'Crae. 2 and 3, J. Cowe.
BARBS.—*Black or Dun.*—1, 2, and 3, W. Meff. *Any other Colour.*—1, 2, and 3, W. Meff.

THE ARCHANGEL.

THIS variety of domesticated Pigeon is not one of the general favourites amongst fanciers; indeed, there are but few who have paid especial attention to its culture, consequently it is not usually seen in this country.

Archangels are not attractive either in colour or habits, and from the casual observer probably no word of praise would be elicited, yet they are a meritorious breed of Pigeon.

Their colour is sombre and unattractive; their shape and peculiarities differ somewhat from other breeds, and in many ways they are dissimilar to others more numerous about us; they are naturally very shy and wild, and this in some degree may account for their being disregarded as "pets."

It is a matter of considerable doubt and speculation when the breed was first imported into Great Britain, and from whence it came. These Pigeons are supposed to be natives of Russia, and have been designated Archangel from the fact of the breed being found in great numbers at that Russian seaport. It is certain that Russia and Germany are accredited with having the Archangel in far greater numbers than ourselves, and in Russia we believe the breed was originally propagated.

The Archangel, as we have said, is not particularly attractive in appearance, but its beauties, as we become familiar with the birds, and as we see them in various positions moving about in the bright sunlight, increase our admiration of them more and more. Archangels, in size and general outline, much resemble the Rock Dove; the head is somewhat of the same form, though the beak has not quite so much of the "spindle" character, and, like the Rock Dove, the Archangel when caged displays that wild uneasy disposition so characteristic of all birds not accustomed to close confinement.

Archangels, though wild and shy naturally, are easily tamed by the common usage of the aviary or dovecote, and when in association with many bold little companions, their retiring disposition is not then so noticeable, as they gradually adopt the habits of their fellows, although they rarely become so tractable as most others; and if proper nesting places are arranged for their use in dark secluded corners they will thrive, breed well, rear well, and live at ease and contentment.

Few words will suffice for detailing the points and peculiarities of this breed. The birds are of moderate size, and though not possessing symmetry of form in a marked degree, still they are not at all ungraceful in appearance. Their body is usually carried in a horizontal position, though the balance is well sustained, and the head inclines a little forward. They are easy in their movements on foot, and rapid in their flight. Their wings are large, the secondary flights being more prominent than usually seen in most other varieties. The head of the bird is narrow, possessing a crest or peak, rising from the back of the skull in continuation of the line of neck, and terminating in a perfect point, inclining forwards. The beak is rather thin, dark-coloured, and somewhat doveshaped. The wart, wattle, or nostril cover is small, smooth, and rather

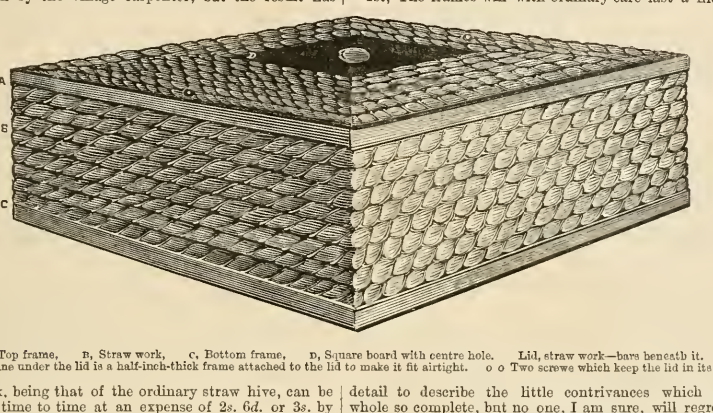
flattened. The eye should be of a red colour, but many splendid specimens have come under our notice having pearl eyes; the red, however, is far preferable, being more in unison with the general colour of the bird. The upper part of the neck is narrow; the breast full, though not too prominent; the shoulders wide, but closely fitting to the body, and not outspread at their sockets. The colour of the birds in a subdued light is a sombre unattractive black; the head, neck, breast, and thighs a reddish chocolate-colour. But in a bright light and under the influence of the sun's beams, this Pigeon becomes all aglow; its sober garb is illumined with varied and brilliantly shining colours from head to tail, from beak to thigh. This chameleon-like peculiarity is an important feature in the breed, and is absolutely necessary in a matured and perfect bird. The head, neck, breast, belly, and thighs as far as the vent, should be of a rich dark coppery bronze; the back, tail, sides of wings, and flight should be black and enlivened by iridescent hues. It is in a strong light that the real colour-merit of the specimen is fully realised.

The young of the Archangel at first are much lighter in colour throughout, but as they pass through each successive moult the richer and more conspicuous does their colouring become. A mistake too often made is to discard young stock too soon—and this remark fanciers of all kinds would do well to consider; therefore our warning is, Do not condemn them at an early period of their existence, see them at least through their first moult; and if then they are not of a bluish tinge or dappled upon their wings, do not condemn them nor hasten their doom; give them time for nature to crop out.—Birmingham Columbarian Society—J. W. Ludlow, *Secretary*.

SHERRINGTON BAR HIVE.

Since the time when Mr. Golding said "Without bars there is something wanting, something wrong," everyone must have desired a bar hive. I have used for some time frames let into round straw hives, somewhat after Mr. Taylor's plan, made cheaply enough by the village carpenter, but the result has not been satisfactory, in that the bars of one hive would not always fit the nitches of another. I have, therefore, schemed a square straw bar hive, and I am glad to be able to recommend it, as combining three great advantages.

1st, The frames will with ordinary care last a life time, and



A, Top frame, B, Straw work, C, Bottom frame, D, Square board with centre hole. Lid, straw work—bars beneath it.
The black line under the lid is a half-inch-thick frame attached to the lid to make it fit airtight. o o Two screws which keep the lid in its place.

the straw work, being that of the ordinary straw hive, can be renewed from time to time at an expense of 2*s*. 6*d*. or 3*s*. by any local worker in straw, the hive becoming indestructible.

2nd, The hives can be used in the open air as well as in a bee-house.

3rd, The price of the hive is only 10*s*.

It is impossible in a few words and without drawings in detail to describe the little contrivances which make the whole so complete, but no one, I am sure, will regret the experiment of procuring one from King & Son, Stoke Goldington, near Newport Pagnel, who make them. I hope this will help to bring bar hives within the reach of cottagers, for whose instruction alone I was some years ago induced to keep bees.—A Bee-keeper.

PAISLEY ORNITHOLOGICAL ASSOCIATION'S SHOW.

The eighteenth annual Exhibition, under the auspices of this Association, was held on the 1st and 2nd inst. in the Drill Hall. It compared favourably with previous years, both in the quality of the birds and the number of the entries. There was a remarkably fine show of *Spanish*, old and young fowls, and the first prize was well merited. The special prize was awarded for a handsome young cock bird. The first prize for a pair of Golden-pencilled *Hamburgh* hens, only five months old, was justly won. The class was an attractive feature of the Show. The *Pigeons* were very superior. The *Canary* and other bird department had numerous entries. The prizes awarded were:—

Spanish.—1, J. Dunlop, Paisley. 2, Miss Hodgart, Paisley. 3, A. Yuill Airdrie. 4, G. Archibald, Paisley. *Chickens.*—1, A. Robertson, Kilmarnock. 2, H. L. Horne, Whiteriggs, Airdrie. 3, A. Yuill. 4, W. C. Hardie, Carron. *Hens.*—1, H. L. Horne. 2 and 3, R. Paton, Kilmarnock.

Dorkings.—*Coloured.*—1, G. G. Neilson, Glasgow. 2, Z. H. Heys, Barrhead. 3, W. Scott, Blantyre. 4, Mrs. Alston, Craighead, Hamilton. *Chickens.*—1, Z. H. Heys. 2, Mrs. Alston. 3, T. Smellie, Kilmarnock. 4, M. Henderson, Ardrossan.

Dorkings.—*White.*—1, J. Bell, Dalmellington. 2 and 4, R. Farrow, Dalmellington. 3, Mrs. W. Arnot, Dalmellington. *Hens.*—1, Mrs. Alston. 2, Z. H. Heys. 3, Miss Hodgart.

Cochin-Chinas.—1, J. Pollock, Busby. 2, T. Bruce, Busby. 3 and 4, J. Drennan, Woodhall.

Brahma Pootra.—1, Mrs. Gillison, Milngavie. 2, Mrs. Alston. 3, A. Carswell, Larbert. 4, H. L. Horne.

Scotch.—1, J. Meikleham, Hamilton. 2, R. Blair, Thornhill, Johnstone. 3, Dunlop, Broomlands, Paisley.

Hamburghs.—*Golden-spangled.*—1, A. Gibb, Ayr. 2, A. Frisken, Irvine. 3, T. Love. 4, J. Crawford, Beith. *Golden-pencilled.*—1, R. Macnab, Cardonald. 2, J. Smith, Stewarton. 3, A. Crosby, Melrose. 4, J. Howe, Paisley.

Hamburghs.—*Silver-spangled.*—1, Ashton & Booth, Mottram. 2, J. Brnce. 3, J. Moodie, Broomlands, Paisley. 4, A. Crosbie. *Silver-pencilled.*—1, A. Cannell, Stewarton. 2, J. Clark, Paisley. 3, R. F. Gemmell, Glasgow. 4, P. Barr

Hamburghs.—*Golden or Silver-spangled.—Hens.*—1, J. M. Campbell, Bonny Kelly, Van Dnr. 2, J. Moodie. 3, M. Currie, Kilpatrick. *Golden or Silver-pencilled.—Hens.*—1, Miss Taylor, Aberdeen. 2, J. Richmond, Kilmarnock. 3, Miss Hodgart.

Polands.—*Topped.*—1, R. Macnab, Cardonald. 2, W. Paterson, Airdrie. 3 and 4, A. Wylie, Johnstone.

Game.—1, D. Harley, Edinburgh. 2, W. Nelson, Johnstone. 3, J. M'Indoe, Grahamston, Barrhead. 4, Z. H. Heys. *Black Reds.*—1, S. M'Coll, Strathblane. 2, G. Williamson, Johnstone. 3, J. M'Lachlan, Charleston. 4, H. L. Horne.

Cross, or Any other Variety.—1, R. Masson. 2, W. A. Orr, Kilbirnie. 3, J. M. Wilson, Lochwinnoch. 4, W. Linton, Selkirk.

Ducks.—*Aylesbury.*—1, J. Meikleham. 2, J. Kerr, Glencart. 3, Z. H. Heys. 4, S. Hunter, Arkleston. *Rouen.*—1, W. Wilson, Johnstone. 2, M. Henderson Ardrossan. 3, A. Gray, Beith. 4, J. Meikleham.

Game Bantams.—1, J. Mitchell, Perth. 2, Gow & Walker. 3, B. M. Knox Kilbirnie. 4, T. Weir, Williamsburgh.

Bantams.—*Black.*—1 and 2, H. L. Horne. 2, S. & R. Ashton. *Any other Colour.*—1, A. Robertson. 2, J. Dunn, Galston. 3, G. W. Boothby, Loath. 4, S. & R. Ashton.

Selling Classes.—1 and 3, J. Kerr. 2, W. White, Paisley. 4, Miss J. Leitch, Cross Arthurlie.

Special Prizes.—*Spanish.—Cockerel.*—A. Robertson, Kilmarnock. *Cochin-China.*—J. Pollock, Busby. *Brahma Pootra.*—Mrs. Gillison, Milngavie. *Scotch.—Cock.*—A. Dunlop, Broomlands, Paisley. *Hamburghs.—Silver-pencilled.*—A. Connell, Stewarton. *Game.*—*Black Reds.*—S. M'Coll, Strathblane. *Game Bantams.*—Gow & Walker, Kilbarchan.

PIGEONS.

Pouters.—*Blue.*—1, J. Murray, Glasgow. 2, J. Millar, Glasgow. 3, J. Lobore, Larkhall. *Black or Red.*—1 and 2, J. Millar. 3, J. Murray. *Any other Colour.* 1, J. Murray. 2, J. Millar. 3, H. Thomson, Glasgow.

Tumblers.—*Short-faced.*—1 and 2, J. Murray. 3, J. Paton, Rigg, Stewarton *Any other Variety.*—1, J. Sharp, Johnstone. 2, W. Wilson, Johnstone. 3, W M'Kinlay, Kilmarnock.

CARRIERS.—1, G. Whyte, Ladyburn, Paisley. 2, J. Murray. 3, J. M'Rae, Kilmarnock.
FANTAILS.—1, J. Sharp. 2, J. Galt, Kilbirnie. 3, A. Crosby, Melrose.
JACOBINS.—1, J. Lobore. 2, J. B. Reynards, Helensburgh. 3, A. Yendal, Galston.
NUNS.—1, W. M'Kinlay. 2, A. Yendal. 3, T. Imrie, Ayr.
TURBITS.—1, J. G. Orr, Beith. 2, T. Smellie, jun., Kilmarnock. 3, J. Muir, Dalry.
COMMON.—1, J. M'Crae, Dalry. 2, J. G. Orr. 3, J. Kerr.
ANY OTHER VARIETY.—1 and 2, J. Murray. 3, G. White.
SELLING CLASS.—1, J. Galt. 2, G. White. 3, J. Moodie.
SPECIAL PRIZES.—*Fowls*, *Ducks*.—J. Murray, Glasgow. *Black* or *Red*.—J. Millar, Glasgow.

CANARIES.

CLEAR.—1, M. Barr, Paisley. 2, R. White, Paisley. 3, D. Halden.
YELLOW—*Cock*.—1, A. Cumming, Rutherglen. 2, W. Wright, Greenock. 3, D. Dick, Kilmarnock. 4, J. M'Pherson, Paisley. *Hens*.—1, T. Fernie, Paisley. 2, J. M'Allister, Glasgow. 3, J. M'Cabe, Kilwinning. 4, J. Wilson, Beith.
BUFF.—*Cock*.—1, H. Pinkerton, Rutherglen. 2, J. Dalziel, Paisley. 3, J. Pettigrew, Carluke. 4, J. Stevenwright, Partick. *Hens*.—1, M. Todd, Paisley. 2, J. M'Lean, Greenock. 3, W. Love. 4, R. Houston, Kilbirnie.
PIEBALDS.—1, Miss M. Houston, Paisley. 2, H. Johnstone, Johnstone. 3, J. M'William, Den, Dalry.
PIEBALD.—*Yellow*.—*Cocks*.—1, J. Pettigrew, Carluke. 2, J. Allison, Paisley. 3, A. Wilson, Greenock. 4, C. Aird, Kilmarnock. *Hens*.—1, J. Scoullar, Kilmarnock. 2, T. Scott, Carluke. 3, J. Pettigrew. 4, R. Houston.
PIEBALD.—*Buff*.—*Cocks*.—1, A. Kelly. 2, T. Scott, Carluke. 3, J. Pettigrew. 5, J. Glasgow, Beith. *Hens*.—1, W. Hunter, M.D., Kilbirnie. 2, A. Crawford, Johnstone. 3, A Kelly. 4, G. Drummond, Renton.
GOLDFINCH MULES.—1, G. Gendie, Ayr. 2, Miss J. Paterson, Airdrie.
GOLDFINCHES.—1, T. Conn, Kilwinning. 2, A. Mitchell, Stewarton.
PARAQUET.—*Home or Foreign*.—1, J. Campbell, Greenock. 2, W. Brown, Kilmarnock.

JUDGES.—*Poultry* : Messrs. W. R. Farquhar, Alexandria ; R. Calderwood, Kilmarnock ; J. M'Lachlan, Paisley ; J. Sharp, Johnstone ; J. Steven, M.D., Ardrossan ; C. Johnstone, Barrhead. *Pigeons* : Messrs. J. H. Fram, Overton, Carluke ; J. Cochran, Glasgow. *Small Birds* : Messrs. J. Fulton, Beith ; J. Lyle, Wishaw ; W. Taylor, Glasgow ; A. Mitchel, Paisley ; J. Gibson, Paisley ; W. Weir, Paisley.

OUR LETTER BOX.

BIRMINGHAM COLUMBARIAN SOCIETY'S SHOW.—"Your reporter, speaking of this Show, says the young Carriers of 1871 were a good class, and the cup bird at Birmingham received but a high commendation. This is a great mistake, for my bird was not there.—W. SIDDONS."

[We have another note on the same subject from Mr. Nightingale, which we cannot publish.]

DIARRHŒA IN FOWLS (*C. H.*).—Try some bread soaked in strong ale, and give no water. Withhold all green food and meat. If this does not make a difference you must give a tablespoonful of castor oil; indeed, if the bird is not weakened by diarrhœa we should begin with the oil. We believe the disorder is caused by some irritating substance that has been swallowed, and cannot be got rid of by ordinary means. After the oil give bread soaked in ale, and no other food for two days.

BASKETS FOR SENDING POULTRY BY RAIL (*A. A.*).—You need only have round wicker baskets made, and cover them with canvas instead of a lid. The height and diameter must be regulated by the number and size of the fowls you wish to send. The basket should be high enough for the cock to stand up without touching the top with his head. You should have no difficulty in having such made, but if you have, apply to Baily in Mount Street.

FOWLS' ROOSTING-PLACE (*A. C. C. H.*).—As a rule, you may safely allow your fowls to choose their own roosting-place, and if they are healthy we do not see why you should interfere with them. If the place they prefer is well protected overhead from snow and rain, and beneath from draught and wind, their choice is not a bad one. Let them have access to their house if they desire it, and they have instinct enough to use it if necessary.

DUCKS (*Anas*).—No; but for security's sake separate them now. They are not early layers, but it is time the intended breeders should be sorted and separated. A *mealliance* is often the loss of a season.

"ORNAMENTAL WATERFOWL (*Sussex*).—At present Carolinas, Mandarins, and Ruddy Shell Drakes; later in the year all the different sorts of wild fowl. Before advising you we should know the locality. Is the water fenced round? Is there a stream near? How large is the water? Are there any islands? Baily in Mount Street will supply you with a priced list.

CHINESE FOWLS (*G. C. A.*).—Your description is not sufficiently definite. They might be Black Cochins but for the tuft of feathers on the cock's head and the black legs of the pullets. What are their combs—single, double, or pea? All Oriental fowls lay yellow eggs. Tell us more about them.

POINTS OF LIGHT BRAHMAS (*A. A.*).—A Light Brahma pullet should have a whitish body with a striped hackle, and black tail and flights. The cock should have white plumage, a black flight and tail, striped hackle, and marked saddle. Both should have pea combs and well-feathered yellow legs. There should be no vulture hock in either of them.

CANARIES (*H. G.*).—Brent's is the best authority. The other book is of another age. We know of no others.

SISKINS (*A Northumbrian*).—Siskins are not judged by any particular points other than brilliancy and condition of plumage.—W. A. BLAKSTON.

SEED (*R. E. H.*).—The sample appears like mustard seed, and certainly not the food I should recommend for Canaries.—W. A. BLAKSTON.

CANARY MULE-BREEDING (*A Beginner*).—Try the Goldfinch and Canary hen A fresh-caught bird will breed this season, but he will not be in trim earlier than May. Put up a Bullfinch hen and Goldfinch, and cultivate patience. You will need it.—W. A. BLAKSTON.

CANARY CHARACTERISTICS (*G. G.*).—I know of no book such as you require. Apart from a detailed list of points (on the distribution of which for subsequent collection into an aggregate much diversity of opinion exists), what is wanted is a series of life-like illustrations, faithful copies of known celebrities, drawn not only with scrupulous regard to detail, but in an artistic style. Wood engravings, such as the Pigeons which appear in these pages from the clever pencil of Mr. Ludlow, would be a great advance on anything which has hitherto been done for the Canary, though I aspire to seeing him placed on a level with coloured plates.—W. A. BLAKSTON.

POISONOUS SCARLET DYE (*A Constant Subscriber*).—We do not think that any scarlet-dyed stockings would paralyse the feet wearing them. The dye might irritate the skin, but we think that would be prevented by thoroughly rinsing the stockings in water before wearing them.

WORMS (*A Poultry Farmer*).—We never heard of any mode of "raising and keeping up a perpetual supply of worms." The Bohemian system must refer to breeding maggots in carrion.

REMARKS

3rd.—Slight white frost, and rather hazy at 8 A.M., fine all day, but still damp. Gale at night.

4th.—Wet and windy early, but cleared up by 9 A.M., fine till 4.30 P.M., windy with heavy rain during the night. Barometer falling very rapidly till midnight.

5th.—Windy till 9 A.M., when it moderated and the rain ceased, fine day but wet evening and night, lightning at 9.30 P.M.

6th.—Dry and fine, rather windy, heavy shower with hail at 0.30 P.M., showery during the remainder of the day.

7th.—Wet early, fair though cold from 10 A.M. to 8.30 P.M., then rain.

8th.—Fine and frosty early, and moderately fine all day, at some times beautifully sunny and bright.

9th.—Very dark, though not either foggy or wet at 8 A.M., but cleared off rapidly and soon became very fine, rain between 4 and 5 P.M.

Although the temperature and pressure have been lower, and the rainfall greater than in the previous week, there has been warm sun on several days.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 10.

WE have not much change to notice here. The general features of the market denote very limited sales, and a large supply of out-door produce keeps the prices from advancing. Sea-kale, A-sparagus, Dwarf Kidney Beans, and Cucumbers are ample for all comers. Continental produce is limited generally to salading, as far as green vegetables are concerned, with the exception of a small consignment of Asparagus.

POULTRY MARKET.—JANUARY 10.

THE market has at last seen the end of Christmas. After the rush of goods there is a cessation. Sellers as well as buyers are carried away by a spirit of Christmas, and as Paterfamilias will at that time deliberately justify an expenditure that at any other time he would deem the height of extravagance, so senders send all they can under the influence of the excitement: hence a factitious scarcity. We will begin our quotations next week.

From observations taken near London during forty-three years, the average day temperature of the week is 42.8°; and its night temperature 31.6°. The greatest heat was 68°, on the 19th, 1828; and the lowest cold 4½° below zero, on the 19th, 1838. The greatest fall of rain was 0.90 inch.

CUCUMBER AND MELON CULTURE.

AN important consideration in most gardens is how to insure a supply of these for the longest time; and, indeed, where proper accommodation is afforded, the first-named can readily be obtained in every month of the year. The form of the structures in which they are grown is of primary importance, and of these ordinary garden frames with moveable lights do very well for summer work, but for early and late supplies they are altogether out of the question. I have had a good deal of experience in this matter, and would unhesitatingly recommend the half-span form of house as being the most useful and best adapted for our purpose. Those at Loxford Hall are of this form, 11 feet wide, and 10 feet from the path to apex of the roof, with front sashes made to open outwards. All the top lights slide, all the back lights are fixed, and ventilators are placed in the back wall. The beds are 5 feet wide, and receive bottom heat from two rows of 3-inch pipes. The internal atmosphere of the house is warmed by four rows of 4-inch pipes, with which we maintain during severe frost a night temperature of 65°, without overheating the pipes or using any outside covering.

Our supply of Cucumbers from Christmas onwards is obtained from plants sown or raised from cuttings early in September. These grow on until they fairly cover the trellis, but they do not bear until the days lengthen, when they commence to fruit and continue to do so until Christmas comes round again. The old shoots must, of course, be thinned-out, and young fruitful ones allowed to replace them, and rich surface-dressings must be given when the plants show signs of exhaustion. I do not know a better variety to afford a continuous supply than that known as Rollisson's Telegraph. I have grown Dale's Conqueror, Hamilton's Invincible, Pearson's Long Gun, and Blue Gown, and have obtained handsome fruit from them; but these, though certainly very showy and well adapted for exhibition, do not keep up a supply all the year round in the way that Telegraph does. Of course it is not necessary to grow Cucumbers in such a house as this during the summer and early autumn months, if dung frames are available, as a three-light frame will help to bring forth sufficient for a very large family. The houses may be used for growing Melons. These, I think, do much better in a house of this description than in frames, the fruit being at all times of better quality. The first lot of Melon seeds should be sown early in January, and under favourable circumstances fruit may be expected from them early in May. Should, however, cold cloudy weather intervene early in the year, it is uphill work for the young Melon plants, and under such circumstances I have had those sown a month later come in as early as those sown first. The details of culture may be summed-up in a few words, and is the same in each case. From the brickbats, which are placed over the hot-water pipes for bottom heat, to the surface of the bed, the depth is 1 foot 6 inches; and over the brickbats there is first placed a layer of turf with the grass side under to prevent the compost mixing with the substratum, and thus filling up the air spaces. Only half the border is filled up at first, and a wall of turf erected parallel with the path serves to keep the compost in its place. The other half of the bed is filled with fermenting material, which not only warms the compost, but creates a gentle bottom heat, and by so doing gives an excellent opportunity for raising young Melon plants or Vines from eyes, striking cuttings, and many other purposes. I generally sow about a dozen Melon seeds in a 5-inch pot, and as soon as the young seedlings are sufficiently strong—that is, when the two seed leaves have grown to their full size—pot them off, one each in the centre of a 5-inch pot, and keep them in the bottom heat until they are ready for planting-out. The bed will by this time be well warmed and ready to receive the plants. Place them about 15 inches from the front wall, putting a stick by each plant to which to train them until they reach the trellis. The material and form of this latter is important.

I know a range of most excellent Melon and Cucumber houses which were built regardless of expense on the most modern principles; one fault only was apparent to me on seeing them, and that was in the trellis employed to train the plants to. This consisted of a series of wooden frames which were made so that they could be fixed at 9, 11, 13, or 15 inches from the glass. This was so far right, but the fault lay in using laths an inch wide, fixed in a longitudinal direction with others crossing them at 6 inches apart, which I fancy very much obscured the light so deficient in January and February. Here we use the same sort of moveable frames, except that stout wire is used instead of laths, and the trellis is moved close to the glass in winter, and withdrawn to the furthest point in the summer months.

When the young plants reach the trellis, the leading shoot is not stopped, but trained up until it is about 1 foot 6 inches from the top of the trellis, when the point should be pinched-out. Side shoots will form rapidly after this, on most of which will be one or two female flowers, and when four or six of them are open at one time the pollen of the male flowers should be applied to them. This is essential, because if one or two flowers are set before others that are three or four days in advance in point of development, those which are set will take the lead, whilst the others will fail to make satisfactory progress. As soon as the young Melon plants are pinched, the fermenting material should be removed, and its place supplied with suitable compost. Cucumbers are treated in the same way as soon as they reach the top of the trellis.

Melons managed on this plan seldom canker close to the surface of the bed when the fruit is on the point of ripening; and most growers know the trouble they have with them from this cause if trained to the surface of the beds. When the plants are attacked by this pest, dry freshly-slaked lime should be applied to the affected parts immediately, and will arrest it. The Cucumber disease mentioned by Mr. R. Fish and others has not, I am truly

thankful to say, appeared in this locality as far as I am aware.

In houses such as I have described a stage is fixed in a space at the back, which should always be occupied with a varied assortment of useful plants. Ours is used for pot Vines, Figs, and Oranges grown for dessert, of which the Tangerine, St. Michael's, and Maltese Blood are the best. I am now gathering the last-named two, and am told that the flavour is distinct and very superior. They require much heat to ripen them, and if the fruit is set in March, the plants must be continued in the temperature of the Cucumber house until Christmas, when it will be ripe.

Tomatoes in pots are also grown on these back stages. Sown about the first day in February their fruit will be ripe about the end of May. They are grown in 12-inch pots in a compost of turfy loam and pulverised bones, and when the proper sorts are chosen it is astonishing what a large crop a pot of this size will carry. Six pots of them are sufficient for my employer's family, and a margin is also left to give away to friends. When growing they require much water at the roots and syringing freely overhead twice a-day. Orangefield Dwarf Prolific is the best I have yet tried for pot-culture. Hepper's Goliath I tried last year. It is said to be similar to the American variety Trophy, but as it grows too tall and carries a crop of very small fruit with one of immense size, it is discarded for pot-culture. Earley's Defiance promises to be an excellent variety for pot-culture. It is said to be fully two weeks earlier than any other kind, and the fruit is large, nearly round, and contains a large proportion of pulp. Gardeners who compete in collections of vegetables early in June will find a good dish of Tomatoes a strong point in their favour.—J. Douglas.

OLD PEARS UNDER NEW NAMES.

BROCKWORTH PARK.

Mr. Rivers seems aggrieved because we have in our advertisements attached our name to the valuable Pear we discovered at Brockworth Park. He says it is pomologically incorrect to do so, until it is proved to be a seedling. Mr. Rivers is an authority, we bow to his decision, and express our regret at having transgressed pomological laws. In our catalogue we call it simply Brockworth Park (without our name), and in future we will do so in every instance.

The important question, however, remains—Is it a new variety, or an old one under a new name? We have known of the original tree some four or five years, and each year have tasted the fruit. During this time we have made inquiry as to its history, and hear that it was received from Cheltenham witot hua name. Mr. Anthony Bubb, of Witcomb Court (the agent to the Brockworth Park estate), knows Pears well, and has a good collection, but he does not know any name for this Pear, although he kuows the tree, and we believe had something to do with planting it. It has been exhibited two years consecutively at the Royal Horticultural Society's Fruit Shows, receiving a first-class certificate in September, 1870 (last October at the International in competition with hundreds, if not thousands of dishes of Pears, both continental and English, and no one could recognise it, though very critical and knowing eyes surveyed it). We believe it was utterly unknown in commerce at the time we brought it out. It bears more resemblance to Louise Bonne of Jersey than to any other sort, but is much larger and handsomer than that variety; it has every appearance of being a cross between it and Williams's Bon Chrètien, but this is only surmise. We can only say, he would be a very rash man who would attempt to palm off an old Pear under a new name before such men as Dr. Hogg, Mr. Barron, and the Fruit Committee of the Royal Horticultural Society.—J. C. Wheeler & Son.

ESTIMATE OF STRAWBERRIES.

As "J. G." desires a few words I will endeavour to gratify his wishes. I am surprised to hear the account he gives of Dr. Hogg. In the chalky land at Rushton and in the strong sandy loam here I have always found the plants do well and crop well. The crop of this Strawberry, and indeed of all the sorts I keep—namely, Rivers's Eliza, Dr. Hogg, Mr. Radclyffe, Wonderful, and Galande, Red Alpine, were grand last season. Cockscomb, the only other Strawberry here, was kept from bearing last year in order to afford early runners. The runners of this and Eliza were planted July 7th, and are now fine plants with several crowns each. "J. G." would find Trollope's Victoria, Empress Eugénie, and Marguerite good useful sorts, which will do well with Eliza, Eclipse, Sir J. Paxton, Cockscomb, and Wonderful.

I should think the above would succeed well in all lands; and, if properly planted in July and well looked after, would overburden "J. G." with fruit. Cockscomb sets every flower, is very large, hangs a long time witnout injury, is Pine-flavoured, but not very good in its colour. Wonderful is very hardy, an immense cropper, Pine-flavoured, colours well except at its points. To effect this the leaves must be penned back. It is one of the best for jam, being so firm after cooking.

Much fuss has been made about Vicomtesse Héricart de Thury; it is the same as Marquise de la Tour Maubourg and Duchesse Trévisse. They were all raised by Jamain and Durand. I had it under the second name. It is a good plant, and the fruit is of a nice crimson colour and of good flavour, but it is not so good nor so much to be relied upon as Rivers's Eliza. The British Queen likes strong irony clay that requires a pickaxe to break it up. La Constante does well in the same stiff clay land. It is hardy as regards cold, but burns in light land, and the crop gets stewed. It is a tufted (the same form of plant as Eliza), dwarf-habited plant. The form of the plant and the form and flavour of the berries are first-rate; moreover, its flavour is quite distinct. Mr. Radclyffe is like the British Queen in leaf and flavour; but it is much hardier, does well in chalky soil (the British Queen likes iron but not chalk), and also in sandy loam, and bears well here. In the last most severe winter I gave my plants of it no mulching whatever. The leaves were less affected by the frost than any other Strawberry here. The others were all mulched.

As regards mulching, beware of excluding air from the crowns for any length of time. A little loose straw put over them during the intensity of the frost may be of service, but it must be removed as soon as the frost is over, or the crowns will be softened. For the many years I have had Rivers's Eliza I have never known it fail.—W. F. Radclyffe.

GREEN PEAS.

I am venturing on a *vexata quæstio* when I touch upon the subject of new Peas, there are so many and such conflicting accounts. New sorts come out with such an unmistakeable character, and are so guaranteed to be good, that it seems to be downright heresy afterwards to question them, while one must expect charges of "not knowing anything at all about it," &c., from those from whom one differs; but as dear old Lord Pam once said to Spring Rice, "You ought, if you want to be a public man, grow a rhinoceros hide." My cuticle has become so hardened that it will take a good thick birch of pea haulm, by whomsoever administered, to raise a blister, and so I must have my say.

Now first of all with regard to earliness. Some one said he had made a computation of the statements made on this point, and that there ought to be no difficulty in having them by the first week in April. Now I must confess this is a point about which I am tolerably indifferent—that is, I do not care to meet my neighbour, the Rev. Smith, and say, "Had any green Peas yet?" "No." "Dear me! what a muff your man must be; I had a dish three days ago." If I can get them in tolerably early time a few days make but little difference to me, and thus a recommendation of three or four days in a new variety is of no moment, especially when one recollects how much soil, situation, the very time of putting in the seed, whether it be favourable or not, and climatic influences, will affect Peas in this point.

Then with regard to what constitutes the real value of a Pea. We must place—at least I would—flavour first and productiveness afterwards. In a large establishment, where the servants' hall has to be considered quite as much if not more than the dining-room, and Jeames is often more particular as to the amount of his provisions than his master, of course productiveness is a great element to be considered, and a Pea like the Cook's Favourite will doubtless win fame with all gardeners whose circumstances require them to furnish large quantities of vegetables, but where flavour is considered it will hold a low place.

New Peas are derivable from two sources—those which are really and genuinely sent, the results of careful hybridising and patient skill, and those which are merely selected strains of some well-known variety, which has been carefully grown on good soil, and then by constant selection improved. Take, for example, Daniel O'Rourke; under how many aliases has

he made his appearance, each contending for superiority, and each only owing its fancied superiority to some exceptional cause! To those at all conversant with catalogues or with the endless varieties of Peas, many instances of a similar character will suggest themselves.

Two raisers of Peas have distinguished themselves, each in their several ways, and both of them from the eastern counties —the late Dr. Maclean, of Colchester, and Mr. Laxton, of Stamford. The Peas raised by the former gentleman occupy a very high place in the estimation of all who prize this favourite vegetable. Little Gem, Advancer, and Princess Royal are highly esteemed; in fact I question if, taken all in all, we have a more general (and most deservedly so) favourite than Little Gem. It is dwarf in habit, prolific, and excellent in flavour.

Of late Peas the largest number of really new Peas have come from Mr. Laxton, of Stamford; and when we mention Alpha, Cook's Favourite, Quality, Quantity, Supreme, without counting those coming ont this season, we see his claim to being a large raiser of new Peas is just. Through the kindness of Messrs. Carter & Co. I had the opportunity of trying these this last season, and as far as my taste goes (and we must remember that in Peas as in other things tastes vary), they are inferior to the Colchester seedlings. Indeed, I have reason to believe that Mr. Laxton's first attempts were not in the direction of quality, but of size and appearance, and in this he has unquestionably succeeded, while in Alpha we have certainly an early Pea with a considerable amount of flavour; and if he works now in this direction, and can superadd flavour to the great size and appearance of such Peas as Cook's Favourite and Supreme, he will have conferred a boon on all lovers of good vegetables. One stands aghast at the guinea packet of seeds advertised by Messrs. Hurst & Co. containing five new varieties; but there seems to be a good deal of character about them, and they may give us, perhaps, that for which we are looking. There are some Peas which in every locality assert their superiority, there are others which are favourably regarded in only a few localities; and I think that a boon would be conferred on all who love good Peas if some of your correspondents would tell us what sorts suit them best, and at the same time say what the soil and situation of their gardens are. I have found Easte's Kentish Invicta in my warm and alluvial soil a very excellent Pea, early, and of good flavour.—D., *Deal*.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 17TH.

THE opening meeting of the year is generally looked npon more in the light of a pleasant *réunion* than as an exhibition; but in the Council room at South Kensington yesterday were brought together what formed in reality a charming little show for the season, affording, too, a pleasing augury of the success that may be expected in spring, summer, and autumn, when Flora and Pomona bring their gifts more plentifully.

The first class in the schedule was for nine Ivies in pots. Messrs. Lane & Son, Great Berkhampstead, took the first place with well-clothed pyramids trained on wire, ranging from 3 to 4½ feet high. Among the varieties were Caenwoodiana, with small narrow-lobed leaves; Gold-blotched; Maculata; Digitata; Rægneriana; Argentea rubra, with small leaves edged with white and rose; and Canariensis maculata, with small leaves mottled with cream colour. Mr. Turner, of Slough, was second with smaller plants.

The best collection of nine hardy Conifers was exhibited by Messrs. Standish & Co., of Ascot, who had a first prize for excellent specimens of Cephalotaxus Fortunei robusta, a fine vigorous plant; Cupressus Lawsoniana fragrans, and Taxus fastigiata aurea, exhibited at the previous meeting; Thujopsis dolabrata; Retinospora obtusa pendula, very handsome; R. filifera, of an extremely graceful drooping habit; R. lycopodioides, one of the most handsome of the Japanese Conifers; and Juniperus japonica albo-variegata, strikingly splashed with white or cream colour. The second prize went to Messrs. Veitch, and Messrs. Lane had an extra prize.

Prizes were offered for the best three dishes of kitchen Apples, also for the best three dishes of dessert Pears. For Apples Mr. Parsons, gardener to R. Attenborough, Esq., Acton Green, was first with excellent fruit of Blenheim Pippin, Golden Noble, and Dumelow's Seedling. Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, was second with Dumelow's Seedling, Alfriston, and Prince of Wales. Mr. Frisby, Blankney Hall, Mr. Ross, Welford Park, Newbury, and Mr. Parsons, Danesbury, also competed. For Pears Mr. Miles was first with Uvedale's St. Germain and Catillac, fine, and Vicar of Winkfield. Mr. Parsons, Danesbury, was the only other exhibitor in this class.

FRUIT COMMITTEE.—G. F. Wilson, Esq., in the chair. This being the first meeting of the year, the question of certificates was brought under consideration. There have hitherto been two certificates granted by this Committee, the first-class certificate being awarded to novelties or improvements in races of fruits and vegetables, and the special certificate for meritorious cultivation of existing kinds. It has been found, however, that a use has been made of the special certificates which was intended only for that of the first-class certificates, and to remedy any disadvantages arising from such a practice, it was decided that in future there shall be but one certificate issued, and that to be a first-class certificate for new kinds or improved races of fruits and vegetables, and that for meritorious culture a *cultural commendation* shall in future be issued, and the special certificate abolished.

Messrs. Stuart & Mein, of Kelso, sent specimens of a very good variety of Scotch Kale, very finely curled. Mr. Taylor, gardener to W. R. H. Powell, Esq., Maesgwynne, Whitland, South Wales, sent some specimens of a good variety of Six-weeks Turnip. Mr. Bray, gardener to W. A. Sanford, Esq., Nynehead Court, Wellington, Somerset, sent a very splendid bundle of Asparagus, which was of so great merit as to obtain the first cultural commendation. Mr. Cryer, the Gardens, Sneyd Park, Bristol, sent specimens of a seedling Onion, said to be a cross between Nuneham Park and Blood Red, but which was considered to be the same as Brown Globe.

Mr. Piccirello, Wigmore Street, exhibited a very interesting collection of foreign fruits and roots, the most attractive portion of which was the wonderful specimens of Garlic, which for size and colour are rarely seen. There were also in the collection Onions such as have been exhibited at former meetings and have been noticed in our reports, Melons, Oranges, Lemons, preserved Chestnuts and Figs. A letter of thanks was awarded for this collection. Mr. Wilson, gardener to Earl Fortescue, Castle Hill, South Molton, sent two remarkably handsome and large specimens of Charlotte Rothschild Pines, weighing 13¾ lbs., from plants seventeen months old. They were awarded a cultural commendation. Mr. Batters, the Gardens, Chilworth Manor, sent a box of Muscat of Alexandria Grapes, but they were too far gone; also two bunches of Black Alicante. Mr. Clarke, gardener to W. Vivian, Esq., Roehampton Lodge, sent a dish of Glou Morçeau Pears which had been well kept, but were deficient in flavour. Mr. Dancer, of Chiswick, sent a dish of Beurré d'Aremberg, excellent in quality and in flavour. A seedling Apple, called Beechwood Foundling, came from Mr. J. Freeman, gardener to Sir John Sebright, Bart., Beechwood, but it was not considered superior to varieties already in existence. Another seedling from Mr. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, was considered good, but not of sufficient merit to justify its being cultivated as a new variety. Messrs. Harrison & Son, of Leicester, sent a seedling Apple, small and round, of a greenish-yellow colour, called Lady Berners, which was not approved, and another called Prince of Wales, of good size and striped, but it, too, was not of sufficient merit.

Messrs. James Backhouse & Son, of York, sent two dishes of the Galloway Pippin which received a first-class certificate last year, and the variety maintained the same high character which was formed of it when the certificate was awarded. Mr. William Paul, of Waltham Cross, exhibited a collection of six varieties of Apples.

A report on the system of keeping Grapes in bottles was read by Mr. Moore, gardener to Earl Brownlow, Belton, which we shall publish next week, and furnish illustrations of the room and the method of keeping the Grapes.

FLORAL COMMITTEE.—W. Marshall, Esq., in the chair. Mr. Denning, gardener to Lord Londesborough, Grimston Park, Tadcaster, sent a fine collection of Orchids, including Lycaste Skinneri, Oncidium aurosum, with a branching spike of numerous rich yellow and reddish brown flowers, O. nebulosum, Ada aurantiaca, Sophronites grandiflora, with very large flowers, Lælia autumnalis, Odontoglossum cristatum, Zygopetalum Mackayi, fine; the white-flowered Saccolabium Harrisoni, Lycaste lanipes, Lælia anceps, and L. autumnalis grandiflora. A cultural commendation was awarded for Phalænopsis Porteana, with two fine spikes of lovely white flowers, with a rosy purple lip tinged with orange at the base, and dotted with crimson. This was very handsome. A first-class certificate was also given to Mr. Denning for Odontoglossum Denisonæ, of the same race as O. Alexandræ, of which it appears to be a large-flowered variety; some of the flowers of this had seven sepals and petals, the others only five; hence there seems to be a tendency towards producing semi-double, or, it may be, double flowers. The spike of this handsome plant had eighteen flowers.

Mr. Williams, of Holloway, sent a group of his new yellow-berried Aucuba, called luteo-carpa. The plants were heavily

loaded with berries, which are ornamental as affording a contrast to the red-fruited kinds. A certificate was awarded to the variety at a previous meeting. Cattleya Walkeriana, in fine bloom and colour, had a commendation. Oncidium cheirophorum, with a branching spike of canary-coloured flowers about 9 inches in length, and Odontoglossum gloriosum majus, were also shown by Mr. Williams.

Messrs. Standish & Co., of Ascot, exhibited a collection of plants, such as Geraniums, Cinerarias, Bouvardia jasminoides, Cyclamens, Lily of the Valley, and Poinsettia pulcherrima. Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, received a commendation for a well-bloomed collection of Cyclamens. Mr. Clarke, market gardener, Twickenham, exhibited a numerous and excellent collection of the same flower, as did Messrs. Veitch. Messrs. E. G. Henderson likewise sent a small collection of selected varieties. Mr. Wiggins also sent half a dozen plants of kinds with the foliage more ornamentally marked than is usually seen.

From Mr. Turner, Slough, came fine baskets of Tricolor Pelargoniums, for which a commendation was given. Mrs. Headley, Achievement, and Reynolds Hole were remarkable for their splendid colouring. Mr. Turner likewise exhibited a dozen berried Aucubas of different varieties, grown as standards of from 2 to 3½ high, with great masses of bright red berries. From Mr. George, gardener to Miss Nicholson, Putney Heath, came a box of cut flowers, including Camellias, Cypripediums, Dielytra, &c. Messrs. Dobson & Sons, Isleworth, sent a collection of white-flowered Chinese Primulas in good bloom. Messrs. E. G. Henderson, St. John's Wood, likewise exhibited a number of seedlings with double flowers. Of these the following had first-class certificates:—Princess of Wales, very double, white; Exquisite, delicate peach; Magenta King, magenta rose; and Emperor, one of the Fern-leaved class, with fine, very double, lilac flowers.

Messrs. Veitch sent a grand collection of white and red Chinese Primulas, as well as the white-flowered Fern-leaved variety; also forced Persian and Charles X. Lilacs, and a box of Lily of the Valley in fine bloom, Hippeastrum pardinum, Rhododendron Princess Royal, a fine specimen of Cœlogyne cristata, Barkeria Skinneri, Cypripedium Harrisianum with one very fine bloom, Odontoglossums, fine specimens of Lycaste Skinneri superba, Saccolabium giganteum. Messrs. Veitch likewise exhibited Oncidium cheirophorum from Chiriqui, already noticed, and a Dendrobium with white sepals and petals and a purple lip.

Mr. Bull sent Dracæna concinna, a plant of graceful habit, with the old leaves of a dark olive, the young shaded yellow and purplish crimson; Crinum amabile, a very showy plant, silvery rose streaked with lilac, and brilliant purplish crimson externally; Macrozamia corallipes and plumosa, and Dæmonorops palembanicus, the last a very handsome Palm; Cypripedium pardinum, with the slipper much veined with green; and an Odontoglossum.

Mr. Lee, Arundel, Sussex, again sent his tree Carnation, Mars. From Mr. Edgerton, gardener to the Countess of Waldegrave, Strawberry Hill, Twickenham, came Cyclamen persicum splendidum with foliage of immense size; one of the four plants had white flowers, the others were not in blossom. Some plants of the Roman Hyacinth were exhibited in excellent bloom, but the name of the sender was not stated.

Messrs. Backhouse, of York, had a commendation for Lælia autumnalis grandiflora, on a block, with eleven large blooms, lovely in colour. From the Society's garden came a nice panful of Ada aurantiaca; and from Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, an Odontoglossum, said to be new, but not so ornamental as many others of the genus.

Commendations were awarded to Messrs. Veitch for their collection of Orchids, also for their Lilacs, Primulas, and Cyclamens; to Mr. Turner for his Aucubas, also for Tricolor Pelargoniums; to Mr. Clarke and Mr. Wiggins for Cyclamens; to Mr. Denning for his collection of Orchids, likewise for Phalænopsis Porteana; and to Messrs. Standish for their group of plants.

The Victoria electric thermometer, an ingenious instrument for indicating and giving notice of changes of temperature in plant houses, was also exhibited. This is the invention of Mr. Rothnie, and has been brought into public notice by Mr. Williams, of Holloway.

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 25.

The effects, immediate or secondary, which are produced upon the trunks and branches of trees by the insects which penetrate the wood, or reside in or under the bark, are very variable, depending upon such causes (beside the habits of the particular insect) as the characteristics of the tree, the soil and situation, and the treatment which it receives from the weather and from man; so that the wood-devourers and wood-borers have furnished a most fruitful theme for many a discussion, and with all our modern researches we are yet in the dark (and likely to be so) on some important points in their economy. The gardener is apprehensive, sometimes too apprehensive, of the injuries he may sustain from species which carry on their work in ambush, and like crafty enemies beleaguering a town, only allow their mining operations to be detected when the victory is already in their hands. The owner of a goodly orchard well stocked with choice trees, may be excused if he heaves a sigh sometimes, when he thinks of the insect enemies which defy fumigations, and syringing, and other expedients he puts in force against the common run of grubs and caterpillars. What can he do to protect himself from the inroads of those larvæ which are not satisfied with inflicting a temporary injury to the leaves, but seek the life-blood of the tree itself? Would it be any good to visit in turn the trees and tap the wood with a hammer, as certain employees are seen on railways operating on the carriage wheels to ascertain if they are "all right?" To carry on a rigid examination frequently, and remove every piece of loose bark, besides absorbing much time, is not a thoroughly effective remedy, for the troublesome creatures frequently contrive to get under bark that is not loose. If the gardener now could manage to give full credence to the theories of those who assert that the wood-feeders form a branch or division of Nature's host of scaveugers, and remove only what is decaying or becoming useless, what a relief it would be to his mind!

It is, however, a fact almost certain, if we are to take the opinion of men capable of pronouncing with some authority, that the number of injurious species amongst the Coleoptera is not so numerous as was formerly supposed. Especially is it so with regard to those in the genus Scolytus; and of a species very well known to us near London Mr. Newman writes confidently thus, as he alludes to it while giving the history of the really destructive Goat Moth. "This," he says, "has caused the death of many valuable Elms, and a beetle (S. Destructor), breeding abundantly in the bark of the dying trees, the injury has been erroneously attributed to this beetle, and not to the true cause, which, feeding and carrying on its work of devastation out of sight, has escaped the notice of superficial observers." It may be stated, however, in passing, that the ravages of the Goat Moth do make themselves obvious in several ways, after the caterpillars have attained some size. In their mining operations they will occasionally come close to the bark and run along their galleries so near it as to render them observable, and, moreover, the odour which the creature exhales is sufficiently perceptible in some conditions of the weather. But the statement for the moment surprises us, if we are at all read in early entomological literature, where such fearful accounts have been given of the injuries done to several species of trees by the Scolyti, and to counteract the ravages of which various expedients in the way of washing, tarring (not feathering), have been proposed. Destructor, as it is called, and rightly enough, though whether it is justified in destroying is a question not finally settled, is one of the largest species in the genus. It does not seem to occur in orchards, but visits trees in pleasure gardens and parks, having a very decided partiality for the Elm, though these little beetles will also be found busy sometimes on the Ash and Lilac, having been preceded in their labours by the huge Goat larvæ already spoken of. Indeed, wherever felled Elms have been left on the ground for some few months, whether sound or unsound previously, they are sure to become the resort of swarms of these beetles, which soon dispose of the bark. The habits of S. Destructor are singular and interesting, and we are indebted to a very accurate entomologist (Dr. Chapman), for some recent valuable information on the subject. The female beetles busy themselves during June and July in preparing for the continuance of the species. This is done by the construction of burrows or galleries, which are 3 or 4 inches long, and a job of about three weeks. Along these the eggs are deposited, never less than one hundred in a burrow, and occasionally half as many more. They are covered with what the Germans call 'frass," principally consisting of the particles of gnawed wood. Whether these serve as food for a time for the newly-hatched larvæ, until they have gained sufficient power to carry on excavations for themselves, I am not prepared to say, but it is possible. The burrow runs near the wood of the tree, and the female, says Dr. Chapman, begins "by making her way along the bottom of some crack in the

bark, often by widening it for a little distance before commencing to burrow, so that the real opening of the gallery is some distance from where the little heap of out-turned frass lies, which marks its orifice." But what is a sort of nursery for the progeny is a tomb for the parent, for, her life's labour thus completed, the female Scolytus dies at the end of the gallery. The larvæ hatch in a few weeks, and form along the inner bark (and also upon the wood sometimes), those curious tracks which have been named "typographs," but are scarcely ever seen quite in their natural form, from the propensity which the different broods have to cross each other's tracks. Some might compare these "typographs" to a map in miniature, on which are delineated a number of rivers and streamlets flowing from a common point. The tracks being filled-up with excrementitious matter as the larvæ proceeds, it is unusual for one to turn round and work back again, though these channels not uncommonly run across each other. The more usual course of things with these larvæ is for them to become full-grown in the autumn, when they eat into the solid wood, and construct each a little chamber where the winter is passed. And Dr. Chapman points out, that owing to this habit they escape being devoured by birds, for as the bark is loosened in the winter by the effects of rain and wind, any exposed larvæ are quickly seized and devoured. In most years, however, a moiety of the brood passes through the course of the larval and pupal states in autumn, and apparently these neither live out the winter as beetles, nor deposit eggs. One instance amongst many others we find of what seems a kind of superfluity in Nature, and like the poet we are half inclined to think sometimes that she is not sufficiently "careful of the type." Dr. Chapman is strong in his convictions that females of S. Destructor have nothing to do with healthy trees; and, therefore, he imagines that the attacks of other insect enemies, or disease in the tree itself have always prepared the way for the inroads of these beetles. Felled trees, however, the species will find out, even while they are in the act of putting forth shoots; healthy trees which are rooted in the soil have a mode of defending themselves from such attacks by pouring out sap into the burrows while they are yet being formed. On the question as to the injuries committed by both sexes of Destructor while visiting trees in search of food, Dr. Chapman does not enter.

I should not be stating the case fairly unless I add here, that in the opinion of Professor Andouin and some others, much harm is done by the attacks of the species upon bark when it is in search of food, so that in this way (as is supposed), through the loss of sap, and the mischief done also by the rain entering through the holes which have been gnawed, the trees are prepared for the ravages of the larvæ.

Two species of the Scolytus which are of some interest to the pomologist, are S. Pruni and S. rugulosus. During last summer a correspondent of this Journal forwarded specimens of bark and wood which had been infested by the former; many of the larvæ were dead, proving that the species is rather delicate, as had been already noted by observers. The burrows of this species are to be found in Apple, Pear, and Apricot, and in all probability in other fruit trees. Dr. Chapman has found no proof of its having ever committed any positive mischief in our orchards, though it, doubtless, accelerates the decay of some trees which, as far as our judgment goes, we should consider healthy, yet some decomposition has secretly set in and is destroying the vitality. In one instance a strip of healthy bark was found to contain a few incomplete burrows, but the beetles had been annoyed by the presence of a fluid which was manifestly sap exuded from the tree. One marked peculiarity in the burrow of Pruni is, that it often begins in a squarish chamber ere it lengthens in a shape like that of Destructor. The males in the latter species make a very short stay in the burrows. In Pruni the males continue in them for some while and devour the excavated material. When of full size the larvæ bore into the wood of the tree to the depth of several lines, and the matured beetles do not emerge until the end of the June following.

The other orchard species, rugulosus, is hardier, and therefore rather more common, and is curious as burrowing occasionally in very slender branches. The opening into the burrow made by the female is not at all hidden, as in some of the other species. This burrow is not much more than an inch in length, and it is lined with comminuted particles taken, not from the bark, but from the wood, so that this "frass" gives an appearance to the gallery which is not observable in that formed by the species previously described. The eggs are laid very evenly, and the larvæ are irregular in their movements, the typograph being quite distinct in its tracery, except in any case where they are unusually crowded. This species is silent. Destructor and Pruni are able to give a vocal performance, in which the abdomen and wing-cases are concerned. Though not exactly quarrelsome, all the Scolyti are in the habit of giving each other a push with the head, should they come into contact. Perhaps it is a mode of friendly recognition, like the custom of rubbing noses which is found amongst some primitive races.

On the supposition that these beetles are hurtful Loudon and others have suggested dealing with them as follows; but the advice should, I think, be taken *cum grano salis*. The advice resolves itself into three particulars. To begin, let us say that you have before a number of suspected trees. With a spokeshave or some fitting tool you pare away the outer bark; and if on examination there are no traces of burrows or small holes in any tree, then it may be pronounced sound, so far as this insect is concerned. Secondly, assuming that on inspection you find traces of larvæ and burrows of the females, then cut down to the wood to make sure, then have the tree felled, and the bark stripped off and burnt. But allow me to add here, that if this is done during the period of hybernation, unless something is done to the wood itself, there will be an emergence of beetles next summer. Thirdly, trees, especially young ones, which have seemingly been visited by the beetles only for food, must be brushed over with coal tar, which is highly displeasing to the olfactory nerves (possibly) of the females. This may be repeated more than once, and is best done in the spring. Instances have been cited by authors, English and continental, where the life of many a promising tree has thus been saved.—J. R. S. C.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 26.

Before a design is drawn to suit a piece of ground it is necessary to find the superficial dimensions and the general

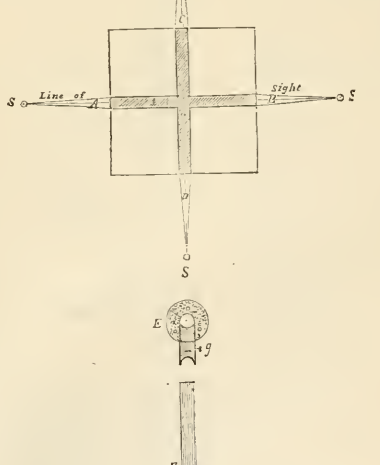

Fig. 51.

outline of the ground on which the design is to be executed, observing accurately at the same time the exact position of

any object, either natural or artificial, that may stand upon or be included in it, such as an ornamental tree, a statue, a piece of water, or a hillock.

To do so correctly it is necessary to have a cross staff. A cross staff can be made in the following manner:—Take a piece of board 6 inches square, and cut two grooves in it at right angles, as A, B, C, D, *fig.* 51; fix a circular iron plate, as E, to the under side of the board by means of three screws. The circular iron plate has a tube attached to it. The tube is dropped on to staff F, and fastened by means of screw *g*. It is also necessary to have some station staffs 5 or 6 feet long, and a measuring tape.

The means employed for finding the dimensions of the piece of ground in *fig.* 52 will be sufficient to illustrate the manner in which to survey accurately any piece of land for general use.

Fig. 52 is an irregular piece of ground, the outline of which is required, and also the exact position of the circles included therein, and the space they occupy. Insert a station staff at each angle, as at A, B, C, D. From A to B is a straight line 57 feet long. Let the assistant take one end of the tape, and also some pegs 12 or 14 inches long. Let him start from station B, taking care to keep in the straight line between stations B and C. At the distance of 13 feet 6 inches from station B insert a peg. At that point there is an offset of 1 foot. At this point it will be seen that it is necessary to find the exact position of circle *a*. Take up the peg at 13 feet 6 inches, and set the cross staff in its place; look through each end of the groove running in the line B C, as, for example, groove A B in *fig.* 51; if stations B and C are seen through the groove, the cross staff is in the right position to erect a perpendicular. Look through groove C D in the direction of the object, as in circle *a*. Send the assistant with a staff, and direct him to put it into the proper place (as near the object as it is necessary or expedient); measure the distance from staff to staff, which in this instance is 9 feet 4 inches, at a right angle with line B C. Find the square of the circle, as hereafter explained, in circle *c*. Let the assistant take the end of the tape and go towards station C, keeping in the straight line between the two stations B, C. At a distance of 33 feet from the point where the staff is inserted at 13 feet 6 inches from station B, on line B C, measure the offset, as at point 3, which is done by placing the cross staff at the point on line B C, taking the sight of stations B and C as before described. Look through the other groove, and direct the assistant to place a staff on the boundary line, as at point 3. Measure the distance from staff to staff, which is 3 feet. From the staff at point 33, on line B C, measure 17 feet, this being the spot at which the boundary line diverges most from the visual line B C, and measure the distance of the set-off as before described, which will be found to be 4 feet. Place the cross staff on line B C (in all cases observing for accuracy through groove A B the stations B C) in a position that the line seen through groove C D shall cut the centre of circle *c*, as at point *d*. The distance required on line B C, from point 17, is 7 feet. Place the station staff at points 7 and *d*; remove the staff at point *d*, and place the cross staff in its stead. Look through groove A B, observing point 7, and through groove C D. Direct the assistant to place the staves at any points, as in *e e*, which will be parallel to line B C; place the cross staff at point *f* on line *e e*, and through the other groove erect a perpendicular, as in *h*, and insert a staff. Place the cross staff in *g*, and in the same manner erect a perpendicular as in *k*. Place the cross staff on one of the perpendiculars thus found, as at *m*, observing through groove A B the points *f h*; and through groove C D direct the assistant to place station staves as in points *s*, *s*, which will be parallel to line *e e*. The circle *c* is thus enclosed in the square *f g n m*, the side of which is 8 feet, being equal to the diameter of the circle. The distance between point 7 on line B C and point *d* is 24 feet. From the station staff at point 7, on line B C, measure 16 feet 6 inches; place the cross staff and measure the offset, which is 2 feet, as before described. From the staff at point 16 feet 6 inches measure 13 feet 6 inches, and measure the offset (1 foot). Find the circle *o* as described in circle *c*. From the staff at point 13 feet 6 inches to the staff at angle C is 22 feet 6 inches, making the total length of the visnal line B C 123 feet. The points thus found on the boundary line (B 1 3 4 2 1 C) will be sufficient to indicate the curve of the line throughout. When the staves are removed for the purpose of taking observations with the cross staff, they must in all cases be replaced.

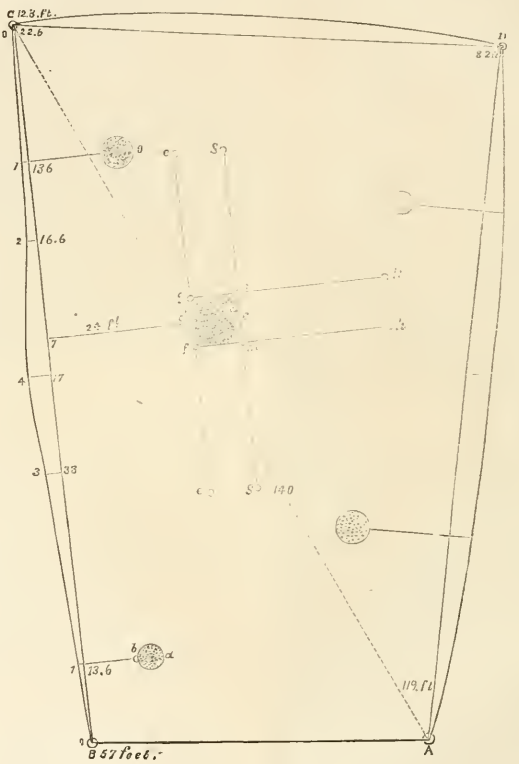

Fig. 52.
Scale 24 feet to the inch.

Enter all measurements and observations in the note book in the following manner, commencing at the bottom of the page and working upwards. The page of the note book must be divided into three columns, the middle column being used to set down the distances from the starting point, as station B, and also the distance of the point to be denoted from the point last named, as shown in the annexed table. Commencing at the bottom line—thus, B is the station point. The first point at which an observation is made is at a distance of 13 feet 6 inches from station B. The second point is

33 feet from the last point, which, added to the 13 feet 6 inches, gives the total of 46 feet 6 inches from station B. Set down 46 feet 6 inches in the next division of the column, and above it the distance to the next point, as 17 feet, add the numbers together, carry the product (which is the distance from station B) to the next division above. Measure the distance to the next point, add them together, and so proceed until the whole of the ground is measured. The columns on the left and right sides are used to denote the offsets and insets respectively, and the position of any object that may occur. They must be filled in as the measurements on line B C (denoted in the middle column) are taken. Thus, the first point on line B C being, as before described, 13 feet 6 inches from station B, it will be found that there is here an offset of 1 foot. Set down in column 1 the offset 1 foot in a line with 13 feet 6 inches in column 2; again, at the distance 46 feet 6 inches, set down in column 1 the offset 3 feet in a line with 46 feet 6 inches in column 2, and so proceed. As there are no insets on the line given by way of illustratiou, the first observation made in column 3 is the position of the circle *a*, this being at a distance of 10 feet perpendicular to line B C. At the point 13 feet 6 inches set down 10 feet in P (perpendicular) in column 3 in a line with 13 feet 6 inches in column 2, and proceed with other objects in the same manner.

P. 148.

In taking the dimensions of a piece of ground it is necessary to measure the length of the diagonal line as shown in dotted line A C, the distance in this case being 140 feet. The lengths of lines A B and B C having been already found, the length of the diagonal line connecting them will at once denote the angle at which they stand to each other.

The pupil will find that it will be of great assistance to him if, when taking measurements, he makes a rough sketch of the ground on the spot, taking a note of any object that may be included in it; it will act as a guide, and greatly assist his memory in drawing a correct plan.—M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

IRON IN SOIL FOR ROSES, AND AUTUMN PRUNING.

In November, 1870, I planted three Maréchal Niel Roses; one in a bed about 4 feet from a south wall, another in a more exposed site, and No. 3 outside the south-east end of a lean-to greenhouse. All grew pretty much alike, rather slowly, until the middle of April, when a sheet-iron flue from the greenhouse had to be replaced by a cast-iron one, the former having crumbled away into rusty laminæ, which were scattered around and over the mulched roots of No. 3. Very soon after this strange top-dressing I found that four strong shoots had issued from the base of the plant, one of which grew so rapidly that in about three weeks it had reached the top of the greenhouse, although trained obliquely, and has now several branchlets; the other shoots lawfully deserve a "vig.," though inferior to the leading one. I cut away the slowcoach to make way for such railroad progress.

Attributing, rightly or wrongly, this sudden start to the accidental mixture of iron with the soil, I collected the fragments of the flue and other iron, old hoop, &c., and strewed them over the roots of three Hybrid "Perpets" (the name I give to my pets), planted in 1870, but not robust with me—viz., Marquise de Mortemart, Madame C. Wood, and Xavier Olibo, and the effect was very visible in the growth and in the colour of the foliage, which became dark and rich; but the experiment was not made until the early part of June; too late, I think, to obtain the same favourable results.

I hope next spring to get a ferruginous liquid by steeping, and to try its effect, with and without guano in the mixture, on all sorts of Roses, Teas, Perpetuals, &c.

The results noticed may be owing to a deficiency in my soil of properties which may exist or even be present in excess in other soils; but a cautious trial can do no great harm in any, and may do good in some, cases. I should be very glad to get a lesson about pruning Roses in autumn for the second bloom. —H. N. O.

[We think your system of pruning quite right, and sufficiently hard. Last season was an exceptionally bad one, and even the finest growth in many cases did not give good blooms, as the buds, owing to the cold and wet, were too long in developing, and many of the petals were rough and unformed. If you erred you erred on the right side, though, perhaps, owing to the season, you gave too much guano. Your cultivation may certainly be fairly called high cultivation, and we have little doubt but that with a favourable season you will succeed. We should advise, as the young growth from the base last year was so strong and healthy, to cut away the old wood freely, and to shorten the young wood to good sound buds, but not to prune them too closely, allowing the shoots on the same tree different lengths, and leaving the stronger shoots the longest. This gives more room for blooms, and prolongs the blooming season. Manetti stocks do not, as a rule, require such hard pruning as the old Briar system, where it was necessary to cut back freely to reduce the size of the head to a symmetrical shape, and where old wood could not be cut out; whereas on a Manetti stock, where young wood pushes freely from the base every year, the older growths can be removed, and there is no necessity to cut the younger wood too severely; but still they ought to be cut back to well-ripened stiff wood.

Your postscript is very interesting, and we shall be glad to hear the results of your further trial with iron as a manure. There is little doubt that yellow loam and clay soils which are rich in iron are good for Roses. In the case you name, the iron being corroded by the action of the smoke would be in a very soluble form, and then would be both carbonate of iron and sulphuret of iron, as well as oxide. The soot adhering to the sides of the old pipes would also contain sulphate of ammonia, which would act at once as a powerful stimulant. Sulphate of iron applied in a very diluted form is a good remedy for mildew, and in our opinion often acts as a tonic (if we may use the expression), and this also may be the action of iron in soils which form so great a proportion of the colouring matter of earth, it may help in many instances to strengthen the plant; but we fear the chemical effects of many substances on the growth of plants is as yet but little understood.—Eds.]

THE PRICE OF VEGETABLES.

Some little idea may be formed of the necessity of a reform in our greengrocery arrangements by the following passage, which occurs in the report of Mr. H. J. Morgan, on the cultivation by means of sewage irrigation of the Lodge Farm, Barking, for the year ending August 31st last, which has just been published. "The average price," says Mr. Morgan, "which our best Potatoes last year realised was from £6 to £7 per ton. This year we have obtained no more than £2 to £2 10s. Onions, which sold last year for £43 per acre in the ground, and realised a great deal more by marketing, have this year been sold by us at £28, the highest price I have heard of being £30 per acre. In the autumn of last year cut Cabbages (Collard's) fetched from 1s. to 1s. 3d. per dozen, while this year there has been a difficulty to obtain 3d. and 4d. per dozen, some having even been sold, I hear, as low as 6d. for five dozen. Scarlet Runners, which made 8s., 10s., and 11s. a-sieve last year, only brought 3d. and 6d. and 1s., until lately, when they have made 2s. and 2s. 6d. a-sieve. Bunching Greens have not paid us to market, and we have hitherto fed cattle on them. I have been told by several farmers that they have ploughed-in their crops, as it would pay them better to use them as manure than to market them. Strange to say," adds Mr. Morgan, with refreshing *naïveté*, "that in the face of all this the retail prices are as high as ever, a cut Cabbage ordinarily costing 1½d., and a small dish of Beans 4d. and 6d., with everything else in proportion."—(*Pall Mall Gazette.*)

THE CARTER CHALLENGE CUP.

This Cup, of the value of fifty guineas, is offered by Messrs. James Carter & Co., the Royal Seedsmen, 237 and 238, High Holborn, London, for competition with vegetables at the great provincial Shows of the Royal Horticultural Society, commencing this year at Birmingham. The Challenge Cup is to be in the possession of the employer, not of the gardener, and when

won three times (not necessarily consecutively) it is to become the property of the competitor so winning it.

A prize of £10 is annually given to the gardener winning the Cup, and a second prize of £3 is offered. The following are

The Carter Challenge Cup.

the conditions of the competition, which is to commence at Birmingham on June 25th—viz., For the best Collection of Vegetables (24 dishes), to include as follows:—Half a peck each of Laxton's Alpha, Laxton's Quality, Laxton's Supreme,

Carter's First Crop, Carter's White Gem, and Carter's Hundredfold Peas; Carter's Covent Garden Garnishing Parsley, Cox's Golden Gem Melon, Naseby Mammoth and Marzagole Onions, French Breakfast Radish, and Carter's Champion Cucumber. All Vegetables to be grown by *bonâ fide* gentlemen's gardeners or gentlemen amateurs, and in the open ground, excepting Cucumbers and Melons. The following to comprise dishes:—Of Onions, 12; Radish, 3 dozen; Melons and Cucumbers, 1 brace; Lettuce, 2; Beet, 3; Potatoes, 18; Savoy, 2; Kale, 2; Cauliflower, 2; Parsnips, 6; Carrot, 6; Leek, 6; Celery, 3.

CUNNINGHAMIA SINENSIS.

This, which we noticed last week in "Les Promenades de Paris," is a plant but little known in the horticultural world, nevertheless it is extremely ornamental when sufficient space can be given it to develope its beauties. It is sometimes to be found in collections under the names of Cunninghamia lanceolata, Belis jaculiflora, and Pinus lanceolata; to the latter genus it is nearly allied.

The Cunninghamia is a native of the southern parts of

Cunninghamia sinensis.

China, and although too tender to withstand the severity of our winter unharmed, it is nevertheless exceedingly beautiful when grown as a conservatory plant; and I have no doubt in the southern and western counties, if a proper position were selected, it would be found to stand out of doors the entire season, or at least with but slight protection.

In its general appearance C. sinensis somewhat resembles the Araucarias from the American continent. It succeeds best planted in a mixture of peat, loam, and sharp river sand in the proportion of three parts of loam to one of each of the others. It may be increased by cuttings, but they do not make such handsome plants in a young state as seedlings, but seeds are by no means easy to be obtained.—Experto Crede.

THE ESPERINE PEAR.

I should much like to know why Mr. Scott fathers on me Esperione as the name of a Pear. I am quite certain I have never employed it or thought of doing so. The name in your paper I judge is a misprint, but of that I have no concern.

I feel tolerably sure that your Edgarley Seedling, the Benedictine, which Mr. Porch suspects was raised from grafts from his tree, and the Coalpit Heath Pear will be found the Esperine. As to the Esperine Pear you have figured, I re-

ceived it nearly twenty years since from my old friend and pupil, M. Jamin, of Paris, but not liking it I discontinued its cultivation. The tree is here still, and I must say differs widely from the true Esperine in its shoots. About ten years since I received another tree from France under the same name. The shoots of this and its fruit are identical with the Pear named by you the Edgarley Seedling. M. Jamin evidently sent me the wrong sort; he still has it in his catalogue as a second-rate Pear. M. A. Leroy figures it, and describes it and its shoots with great accuracy, making it of first quality. Its shoots—and I place much value on their evidence—correspond exactly with M. A. Leroy's description, *les lenticelles* (freckles), are large and very plain, so that its shoots may at once be distinguished from any other kind. Such are the shoots on my tree, and on those of trees received from Mr. Porch. I should add that Mr. Porch saw this Pear, or what he supposed to be the same, on some old French trees in Mr. Young's nursery at Taunton. There is, therefore, no doubt but that the Edgarley Pear is French, and the true Esperine. The Benedictine may at once be distinguished by attention to its shoots of one year old. Mine (very young and small), I confess have not the freckled character. As to the size of the Edgarley Pear, Leroy says of Esperine, "It is above the middle size, and sometimes larger." With regard to the outlines of Pears, they often vary so much. See numerous instances in the Dictionnaire, and more particularly in page 280, in Henriette Bouvier, two figures, one of which has a long stalk, and the other a short stout one, one round and the other "turbinée obtuse," so that no one would think them to be the same.

If there is any doubt as to the Benedictine Pear, it may easily be solved. The present tree cannot be very old. An honest good judge like Mr. Cramb could at once tell us if it is a seedling or not, and thus put the question at rest. Let it, therefore, be done.—T. Rivers.

[The fog thickens. We have received a handbill issued by Mr. Sampson, of Yeovil, in which he states that the Benedictine Pear "was raised from a cross between Huyshe's Prince of Wales and Van Mons Léon Leclerc, by William Lovell, Esq., of Glastonbury." Now, this settles the question at once as to its *not* being identical with the Edgarley Pear. Huyshe's Prince of Wales was not distributed till 1859, and Van Mons Léon Leclerc was not known in this country till 1844, and we leave others to say if a seedling raised from these newly-introduced varieties, could in 1865 have produced a tree of which the oldest inhabitant of Edgarley could not remember the age. We ought to state that on reference to Mr. Rivers's manuscript we find that Esperione is a misprint.—Eds.]

A SOJOURN IN THE HIGHLANDS OF SCOTLAND.

We have long had a desire to visit the Highlands of Scotland. So much has been said and written about Ben Lawers that there are few botanists who have not had a desire to see that fine mountain. All the British botanists of note, and even some Continental ones, have paid their respects to Ben Lawers.

The early part of September is a favourable time for making a botanical trip, the heat of summer has somewhat moderated, and the days are sufficiently long to afford time for a mountain ascent, and enough work can be done to tire much younger persons than ourselves. The beginning of last September was somewhat showery and unfavourable for excursionists, but became more settled about the 6th and 7th of the month, and there were satisfactory indications of a spell of fine weather. This being so, and other circumstances favourable, Mr. T. Mitchell and myself determined to visit the Highlands, making for Killin, the very heart of them, as head-quarters in the first instance.

After arriving at Killin on the third day out we travellers, after breakfast, went out with the view to ascending Craig Curich, the nearest mountain, something over 3000 feet, and a fine feature in the landscape. As the weather seemed somewhat doubtful, we consulted certain of the natives who were hanging about. The men said it would be fine; but a fat damsel said we would not get to the Craig, as it was going to be wet. Wishing it to be fine, we heeded not the fat lady's predictions, and pushed on. For about a mile the road was level, but then it began to rise up a woody steep, partly following the course of a small stream. Here we saw many fine trees, chiefly coniferous ones, and passing through immense quantities of Brackens, with the Sweet-scented Mountain Fern (Lastrea montana) everywhere plentiful, up and up we went to the height of 1000 feet. Here we left the woods and Bracken, and entered upon a large tract of Heather, miles in extent. The margins of the stream began to show alpine vegetation, the Cloudberry (Rubus Chamæmorus), and the yellow Mountain Saxifrage (Saxifraga iroides), being abundant, and succeeded by the Alpine Lady's Mantle, Alchemilla alpina, and Oxyria reniforme. The opposite-leaved Saxifrage (Saxifraga oppositifolia), the Alpine Meadow Rue (Thalictrum alpinum), and the rare Tofieldia palustris also presently came to view. After much toil we reached at the base of the cliffs the "talus," which consists of immense quantities of material that has fallen from the cliffs above. These cliffs are nearly perpendicular for 800 or 1000 feet, but can nevertheless be traversed and explored at certain points here and there. Before we had fairly arrived at the foot of the cliffs the clouds came drifting down upon us, and the wind roared among the rocks above like the sound of innumerable railway trains moving about and around us all at once. The rain began to come down, and we were compelled to take shelter under a projecting rock. At times the clouds in which we were enveloped were so thick as to make it almost dark, and "The wind blew as 'twould have blown its last," roaring and howling most fearfully. Now and then the rain abated somewhat, and in these intervals we sallied out, and managed to get some thirty to forty good plants of the rare Holly Fern (Polystichum Lonchitis). For nearly three hours were we confined in this den on the mountain; after which the wind subsided, the clouds rose like a curtain, and the rain ceased. Evening was, however, drawing on, it was growing dusky, and as the descent the mountain in the dark, with no roads, would have been more difficult and dangerous than its ascent, we hastily quitted our den, waded through the dreary tract of bog and Heather, and reached our quarters before it was absolutely dark, not much worse for our journey, with the exception of a thorough soaking of the legs and feet.

On the fourth day we rose in good time. The morning was fine, and there was every appearance of settled weather. We breakfasted, and then started for Malgurdie or Mealgurdie, a lofty mountain about 3400 feet in height, six or seven miles to the north-west of Killin. We had learnt from some of the Killinites that this mountain was an excellent one for plant-hunting, and was seldom visited, as most people contented themselves with Ben Lawers. We passed up the valley of the Lochay, and after proceeding about four miles up the valley we came to the falls of that name. Here the valley contracts, and the waters of the Lochay are precipitated over a series of rocky escarpments of no great height. The stream at first roars, froths, foams and bubbles, and then silently, sleepily, and sluggishly steals on to Loch Tay. The timber in this part of the valley was very fine, the Larch and Spruce Firs being as straight as needles, and of great height.

It was very pleasing to watch the squirrels running up the trunks, then along the branches, and then jumping from tree to tree with their usual agility. Soon after leaving the falls Malgurdie came in view, a fine old fellow, but still far away. It was perfectly appalling to think of climbing up his huge breast and shoulders, and we did not think ourselves equal to the task. But, oh! those rocky cliffs, which we could indistinctly see near the summit, were so tempting that we could not resist. It was in vain to wish for wings, or a balloon, or any other possible or impossible means of ascent. For some time we vacillated between hope and despair; on the one hand there was the mountain of Heather piled up to the sky, with a rocky corona, and we somewhat fatigued by our six-miles walk from Killin, and labouring, moreover, under the burden of years, although possessing the spirit, wanted the physical strength and energy of youth. On the other hand, the day was gloriously fine, neither cold nor hot, temperature about 60°, lower than which it should never be if we had the thermal control. Not a breath of air disturbed the slender Birchen spray, not a cloud streaked the mountain; it was as if the ruder elements held holiday. Then that crown of rock on the summit was worth a severe struggle to reach—such a concurrence of circumstances rarely occurs, and, very probably, never would occur to us again.

If the day had been made for our exclusive benefit it could not have been better devised, and to neglect so good an opportunity would be almost a crime. Accordingly we scanned the mountain, narrowly noted the difficulties of the various routes which might be taken, and finally laid down our plan of attack. At this moment a tourist from Edinburgh, with map in hand,

overtook us, and inquired if the mountain before us was Malgurdie, to which we replied in the affirmative. Were we going to ascend it? We were thinking of it. Would we accept his company? Yes.

We started. The first half-mile or so was land partly enclosed, then nearly a mile of Grasses, Bents, and Heather, and then we know not how many miles of Heather before we came to the rocks which had tumbled down from the cliffs. In the ascent we took a short rest about every 500 feet, and these rests, together with sundry draughts of the Scotch beverage, enabled us to ascend with less fatigue. We met with four Lycopods—Lycopodium Selago, L. selaginoides, L. clavatum, and L. alpinum; also the Scotch Crowberry (Empetrum scoticum), which we here saw for the first time in its native habitat. We now set about exploring the rocks, met with Vaccinium uliginosum, and then Cornus suecica. Our joy at seeing this alpine gem *in situ*, for the first time in our lives, was almost unbounded. Then Pseudathyrium alpestre, Lastrea dilatata alpina, and the Holly Fern in plenty. We shouted "Bravo! Bravo!" The Least Willow, Salix herbacea and S. reticulata, were both there; then the Sibbaldia procumbens, Rhodiola rosea, and a host of other alpine gems which it would be too tedious to detail.

We lingered among these rocks till after the sun had set, and if we had possessed the power of the son of Nun his solar majesty would have stood still on the western mountains for many an hour. It was quite dark before we got to the foot of the mountain, and we had some difficulty in finding the road, along which we had to tramp in the dark to Killin. We ultimately arrived at our quarters a little before ten o'clock.—(*Extracted from Mr. Stansfield's notes read before the Todmorden Botanical Society.*)

(To be continued.)

THE SUCCESSION AND COMPARATIVE MERITS OF LATE GRAPES.

In common with most gardeners, I am much interested in the discussion of the merits of the newer late Grapes, and pleased to see Mr. Donaldson bringing Mrs. Pince so well forward. Mr. Freeman's remarks will assist in fixing the position of Madresfield Court Grape. Both are grand Grapes and late; but there are late, later, and latest Grapes.

Now, for late Grapes to ripen and be in plump condition after the Hamburghs, I should prefer Muscat Hamburgh and Madresfield Court, both with about the same consisteney of skin, the former the smaller and better flavoured, the latter the larger, and keeping its flavour longer. Each is in season until the 1st of January—the Madresfield Court even later.

Of later Grapes I put Alicante first, and accompany it with Mrs. Pince; both will bridge over February well. The first-named is the better-looking for bloom and colour, and carries its bloom persistently. Mrs. Pince, however, eclipses it in flavour, and is also larger in berry. It is rather amusing to bring to mind that on its *debût* Mrs. Pince was represented to be of the size of the Black Prince.

The latest section must be filled up with Lady Downe's, without any other black Grape. It has a particular merit of its own, which, with its other qualities, strikingly fixes it as being the best of the latest kinds—namely, its quality of improving in flavour with age.

The keeping properties of the three sections mentioned above do not seem to depend on the amount of the saccharine matter which they contain, as has been attempted to be shown—the idea, no doubt, being taken with much plausibility from the results of the confectioner's art—but upon the comparative thickness of the skin. Indeed, one of the demerits of Lady Downe's, in the estimation of those who have most to do with eating the berries, is that the skin is too thick, but its keeping qualities quite make amends for that. We may say of it in the words of the old song—

"Some say its beauty 's but skin deep,
Its skin's so thick 'twill always keep."

I have a late vinery planted with a Vine each of Madresfield Court and Muscat Hamburgh, three Vines each of Alicante, Mrs. Pince, and Lady Downe's, all with their roots entirely inside, and all in the rudest health, and I think there is an excellent opportunity for making a comparison of the sorts. By far the largest berries in the house are on Mrs. Pince, many of them being 1½ inch long by 1 inch wide, the flavour excellent, but they are deficient of colour about the stalks. It sets perfectly, quite unlike the Muscat Hamburgh.

The finest-looking for colour and bloom, and perhaps shape of bunch, is the Alicante. The strong point in the Madresfield Court is its adaptability for late autumn. For flavour I turn to the Muscat Hamburgh, leaving out of account three Vines of Bowood Muscat in the same house.

This reminds me of white Grapes. I should like much to hear something about the White Lady Downe's, whether its properties are indeed equal to those of the black. I think it deserves a thorough, and it must have an extensive, trial to prove it.—W. D. C.

PEACHES AND DRYING FRUITS IN DELAWARE AND MARYLAND.

I made a visit in company with a few friends through a portion of these States, and saw large orchards, from one hundred to over one thousand acres each. The quantity of fruit was so large that the growers received but a small amount for their labour. We visited one orchard of over one thousand acres where all the fruit was canned, between five and six hundred hands were employed. They canned four thousand baskets per day, and kept seven waggons employed carrying the Peaches to the house. The cans were made on the place, and all the workers, half or two-thirds females, were lodged and boarded on the premises, the men and women in separate houses. The skins or peelings, and the poor and refuse Peaches, were distilled on the place into brandy, making about forty gallons per day on the average.

At one of the towns there is a drying establishment on a new plan by steam. It is simply taking out the water, leaving the fruit with its good flavour, and when wanted for use, add water and sugar sufficient to be palatable. It takes four hours to dry the fruit, eight bushels can be dried in an hour by one machine. They had two set of hands, one for the day and one at night. All kinds of fruit and vegetables can be dried in this way. They commence with Strawberries and Raspberries, and continue on with other fruits until Peaches are ripe, after they are done. They finish off with Tomatoes, green corn, and Sweet Potatoes. A bushel of Tomatoes or Strawberries can be pressed into a space of 6 or 8 inches square, which makes it convenient for the army and navy, and for travellers.—C. D.

SANDRINGHAM HOUSE.—No. 1.

A few weeks ago were centred on Sandringham the fears and hopes of England, and not of England only, but of England's wide dominions, and of all the English-speaking race. Now, happily, the cloud which overshadowed it and us is passing into sunshine; those fears which were of the darkest have given place to hopes which are of the brightest, and in his return to health the Heir Apparent will find himself the most popular, the most valued man in England. And the sympathy of all classes and all creeds for the affliction of the Prince, his amiable Consort, and his Royal Mother was so widespread and heartfelt that no one who had not mingled with the masses of the people at the time could realise its fulness and sincerity. Then Sandringham was in all men's mouths, then everything pertaining to Sandringham was of keen interest, and now that the danger is past we may without impropriety give an account of a place of which the name will never be forgotten in our generation.

"What has been shall be again," was the utterance of an old fortune-teller, who certainly had never heard the adage, "History repeats itself." Sandringham is an illustration of the two sayings, for this estate of the heir to the throne was once the possession of Harold, King of England. When he died on the field of Hastings, his conqueror bestowed Sandringham on his Norman follower, Robert Fitz-Corbon.

It is named Saint Dersingham in the "Domesday Book," and the name is compounded of Saxon and old British words, *sand*; *der*, water; *ing*, a meadow; and *ham*, a dwelling—that is, a residence in a sandy wet meadow.

We will pass over various possessors until we come to William Cobbe de Sandringham, in the reign of Henry VII., who by will directed that his body be buried in the church of St. Mary Magdalen of Sandringham. It remained the property of the Cobbes until about 1686, when it was sold to Sir Edward Atkins, Lord Chief Baron of the Court of Exchequer, from whom it passed to the Hoosts and Henleys. In 1829, Henry Hoste-Henley resided here. Subsequently the estate passed to the Hon. Spencer Cowper, and was purchased by the late Prince Consort shortly before his death.

The estate is situated on the northern side of the county of Norfolk, about eight miles from King's Lynn, and on one side is bounded by the broad estuary of the Wash. The nearest station to it is Woolferton on the Great Eastern Railway—a remote station between which and London there are three trains a-day each way. It is a wild-looking road in winter that from Woolferton to Sandringham, over a hill, through Ferns, through young plantations of Conifers, through a wild heath, passing not a house till one reaches that of Sir William Knollys but a short distance from the Norwich gates. These were the work of Messrs. Barnard, Bishop, & Barnard, of Norwich, and exhibited at the International Exhibition of 1862; afterwards they were presented to the Prince by the county, and now form an appropriate and dignified entrance to the grounds. But before entering these we must pause to remark that on the estate a peculiar sort of carr or ironstone is largely dug out of the heath, where it is found close to the surface. It is soft and crumbling when recently dug out, has the appearance of, and often is called, "brown sugar." Sir Robert Walpole used it for constructing the walls of his stables at Houghton, and the same material has been extensively employed in building the boundary walls of the pleasure grounds, the offices of the mansion, and many of the cottages. Thin pieces of this stone are held together by mortar which, however, does not extend to the face of the wall, and the latter, consequently, has a somewhat rustic appearance. Where employed in the offices of the mansion and other buildings, stone facings at the corners give a finished appearance.

Sandringham is in a county celebrated more than others for its productions of botanists and fruit trees, and, as we shall presently show, the garden at Sandringham fully maintains the reputation of its county for fruit trees. The county's prolificacy of the latter may be traced, probably, to its former exuberance in monastic establishments. Monks were celebrated for their

Old Sandringham House—West front.

attention to gardening, and how they superabounded in Norfolk may be appreciated from the fact that of 1148 monasteries sequestered by Henry VIII., seventy-nine were in Norfolk. Confining our attention to Apples only, the following have this county for their birthplace:—Col. Harbord's Pippin, Caroline, Winter Colman, Winter Broadend, Harvey's Apple, London Pippin, Baxter's Pearmain, Belle Bonne, Hubbard's Pearmain, Winter Majetin, Fouldon Pearmain, Horsham Russet, White Stone Pippin, and Winter Quoining. Whether the Beefing originated in Norfolk is doubtful, but it was so early and so largely cultivated there as to be usually called the "Norfolk Beefing."

Knowing the reputation of Sandringham for fruit-production, —a reputation soon gained and well upheld, as witness the lead Mr. Carmichael took on more that one occasion in competitions for prizes offered by this Journal against some of the most skilful gardeners in the country—the fruit and kitchen garden was that part of the place which first engaged our attention. But in passing through the pleasure grounds on our way thither we could not but remark the great changes which have been made. The old house, of which we give a representation, has been pulled down, and a handsome new mansion, only completed last autumn, has been erected in its place from the designs of A. J. Humbert, Esq., of London. The greatest drawback is that the site is so low; and although the old pond which was in front of it has been replaced by a lake further removed, still there is more of mist in the early morning than is either desirable or healthy. A better position might have been, and would doubtless have been, chosen had it in the first instance been settled that an entirely new mansion should be erected, but only a reconstruction was at first intended, and the result has been a new house on the old site. There are many pretty views, especially from the terrace, whence every here and there one obtains glimpses of the church to which a path leads through an avenue of Scotch Firs, with a breadth of turf on each side of the gravel, a portion of the undershrubs having been removed to give place to the grass. We will now pass on to the kitchen garden, the main object of our visit, deferring till a future occasion a notice of the new mansion and its surroundings.

The kitchen garden at Sandringham forms one grand parallelogram of 900 feet by 315 feet within the walls, or rather more than 6¾ acres, besides which there is more than 8 acres of ground in outside slips, bringing up the total area to 15 acres. It will thus be seen that it is one of the largest kitchen gardens in the kingdom; and that it is also one of the most complete as well in its broad comprehensiveness as in its small details can likewise be affirmed. When it is considered that only six years ago this was a Turnip field, and that in a few months afterwards the walls were built, the ground prepared, the trees -

planted, and that now these walls are covered almost to the top with trees excellent in kind, in health, and in fruitfulness—it must be admitted that even with the great means at command the result obtained is a marvel, not only of expedition but also of completeness, yet this result is a solid and permanent one, not one of Mushroom growth, springing up in a night and decaying as fast. The story of the gardener and the farmer is worthy of the attention of the brethren of the plough, who too often look down upon him of the spade, and despise the lessons which they might gather from his practice. One day Mr. Carmichael set his eyes on the Turnip field, satisfied himself it would suit his purpose, and told the farmer he considered that the best place for the new garden. It is a pity we cannot give the vernacular, but great was the farmer's amusement. "Make a garden of that!" the idea was preposterous—only the farmer did not use so long a word, considering the gardener less wise—to put it in the mildest form—than he should be. But the garden was made on that same field, and instead of indifferent Turnips, grow, and flourish, and fruit Peaches and Apricots, Plums and Cherries, Apples and Pears, as well as every kind of vegetable crop. The means by which this success has been attained is intelligent high culture. Intelligence and high culture, then, are the moral to the tale.

The site of the kitchen garden is a little to the north-east of the mansion, near it yet perfectly concealed from view by high trees, which also shelter it from sea-sweeping winds—for the sea and the long low line of the Lincolnshire coast can be seen as one drives over the hill from Woolferton station. The ground within the walls is laid out so simply that the arrangement can be understood without the aid of a diagram. Within the oblong is a long straight-sided oval skirted all round by a 15-feet-wide drive, and at the corners quarters of Gooseberries and Currants at one end, and of orchard trees at the other, follow the sweep of the oval on one side, and a line

The path to Sandringham Church

parallel to the walls on the other two. Further, a broad walk passes through the centre of the garden lengthwise, and another crosses it at right angles also in the centre, and at the intersection of the two is a circle with a large basin for water. This arrangement, as just remarked, is very simple, and it is as effective as it is simple; indeed we know no garden which so strikes the visitor with its greatness of extent on first entering it, for most large gardens, partly from necessity, partly from choice, are cut up into compartments by cross walls. The south-aspect wall on the north side of the garden—in other words the principal south wall—like all the others, is 14 feet high, except where the vineries and Peach houses are placed, where it is higher in proportion to their various heights. This and the other walls, which are only 12 feet high, are 14 inches thick, and built in *English bond as being stronger than Flemish bond—that usually employed. All the copings are of Arbroath pavement, project 3 inches, are grooved to throw off the drip, and give a good finish to the walls. In front is a border 40 feet wide, then the 15-feet drive, next 100 feet of ground between the drive and 8-feet central walk, then another 100 feet of ground, the drive, and the north-aspect wall and border. The central area is crossed at every 75 feet by alternate lines of Apple and Pear trees, the former grown as large bush trees, the latter as pyramids with the branches trained downwards to iron circles 3 feet in diameter fixed to oak posts, rising 6 inches above the surface of the ground to allow of the hoe being passed beneath. Many of these Pears have already attained the full height to which they are to be allowed to grow, and the whole form handsome trees, and productive as well. These have 8 feet of border kept free of cropping, and being placed so far apart it is easy to cart manure on to the ground, which would not be the case if the trees were planted in lines parallel to the south wall instead of at right angles to it.

The conversion of such an extent of ground from farm land to a well-ordered kitchen garden must have been a work of great labour. Fortunately the surface was tolerably level, so that the task of reducing eminences and filling up hollows was not so great as in some cases; still towards the east end the ground rose about 6 feet, and this elevation had to be reduced. The subsoil, being in this part chalk, was taken out and used for bottoming the walks and drive. Generally the soil is a light free sandy loam lying on carr, but in this part of the garden it is rather stiffer and may be described as a chalky loam. The whole of the ground was trenched from 2½ to 3 feet deep, a layer of manure placed at the bottom of each spit, and another layer over every subsequent spit, the last layer being covered with the shovellings from the bottom of the trench.

Having now given some account of what may justly be termed the rise of Sandringham, and described the laying-out of the kitchen garden, we shall in our next enter into the way in

* The differences between these modes of laying bricks, as well as much information on the construction of walls will be found in vol. xiv, New series pp. 50, 51.

which that garden is cultivated, and the improvements effected in other parts of the grounds.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Crinum brachynema. *Nat. ord.*, Amaryllideæ. *Linn. arr.*, Hexandria Monogynia.—A fine sweet-scented plant, a native of Bombay, whence it was sent to Kew in 1870. The bulb is large, conical, and straw-coloured; the leaves nearly 2 feet long, entire, smooth, unfurrowed, and bright green. Spathes somewhat red at the points. Flowers white, drooping, and fragrant.—(*Bot. Mag.*, 5937.)

Sphæralcea miniata (Vermilioned Sphæralcea).—*Nat. ord.*, Malvaceæ. *Linn. arr.*, Monadelphia Polyandria. The "Painted Mallow" was introduced into England by the Marchioness of Bute in 1798, and was grown both for purposes of greenhouse decoration and that of shrubberies in October and November. Its liability of succumbing to frost, however, led to its discontinuance as an out-doors flower. It is a branching undershrub, covered all over with white down, having vermilion-red flowers in cymose racemes, and obcordate petals, somewhat purple at the base.—(*Bot. Mag.*, 5938.)

Gilia achilleæfolia (Achillea-leaved Gilia).—*Nat. ord.*, Polemoniaceæ. *Linn. arr.*, Pentandria Monogynia.—A native of California, discovered by David Douglas in 1833. An erect annual, with the habit of the Scabious, but more pubescent and woolly at the nodes. Flowers globose, of a fine cobalt-blue, covered with large projecting stamens. Style exserted. Stigmas three.—(*Bot. Mag.*, 5939.)

Agave Besseriana (Besser's Agave). *Nat. ord.*, Amaryllideæ. *Linn. arr.*, Hexandria Monogynia.—Leaves in a dense rosette, each one ending in a hard brown spine, and having a contraction towards the base, where the leaf again expands so as to form a semilunar sheath; upper surface slightly, lower very convex; marginal spines upturned, brown. Perianth-tube long, narrowly pitcher-shaped, six-furrowed at the top, dark green; lobes green on both sides and brown at the ends. Filaments yellow-green, longer than the lobes; anthers orange-yellow. —(*Bot. Mag.*, 5940.)

Ophrys lutea (Yellow Ophrys). *Nat. ord.*, Orchideæ. *Linn. arr.*, Gynandria Monogynia.—A native of Southern Europe, extending from Crete to Smyrna, and along the coast of Africa from Morocco to Tunis. Petals yellow or yellowish green. Lip nearly quadrate, golden yellow with a purple disk; disk velvety, maroon purple, with a polished blue or violet centre. —(*Bot. Mag.*, 5941.)

Lithospermum petræum (Rock Lithospermum). *Nat. ord.*, Boragineæ. *Linn. arr.*, Pentandria Monogynia.—A native of Dalmatia, small, much-branched, with short close-set hairs. Flowers in revolute terminal cymes, dense cymes, deep violet-blue. Stamens with large exserted anthers.—(*Bot. Mag.*, 5942.)

Macrozamia corallipes (Coral-footed Macrozamia). *Nat. ord.*, Cycadeæ. *Linn. arr.*, Diœcia Polyandria.—The genus to which this plant belongs is peculiar to Australia, where it ranges from the tropical to the temperate zone. Trunk subspherical with a truncate base, 8 inches in diameter. Leaves forming a very contracted crown, pinnate; pinnæ about fifty pairs. Male cone 7 inches long, narrow-oblong, bearing a small sharp point on the lower scales, and an erect spine on the upper. Female cone shorter and stouter than the male, being about 4½ inches by 3½ when in fruit; the lower scales with a triangular point, the upper with an erect spine. Seeds orange-red.—(*Bot. Mag.*, 5943.)

Gladiolus purpureo-auratus (Purpled-golden Gladiolus). *Nat. ord.*, Irideæ. *Linn. arr.*, Triandria Monogynia.—This plant came from Natal, where the genus seems to be particularly varied and handsome. Stem 3 or 4 feet high. Leaves 6 to 9 inches long. Flowers arranged on a spike; the perianth nearly regular, pale golden yellow with a large purple blotch. —(*Bot. Mag.*, 5944.)

Senecio pteroneura (Winged-nerved Senecio). *Nat. ord.*, Compositæ. *Linn. arr.*, Syngenesia superflua.—A native of rocky and sandy hills on the Moroccan coast. It was only introduced into England last spring. Branches articulate-cylindrical, with three longitudinal ridges running down from the leaf-scars. Involucral scales green, brownish red about the middle. Flowers about thirty, spreading, pale straw-coloured.—(*Bot. Mag.*, 5945.)

Kniphofia caulescens (Stalky Kniphofia). *Nat. ord.*, Liliaceæ. *Linn. arr.*, Hexandria Monogynia.—A native of South Africa. Trunk 6 to 10 inches high, with short fleshy roots. Scape 6 to 10 inches high, erect, green, with many scattered bracts. Flowers pendulous, numerous. Perianth yellow when young, deep blood red after expansion.—(*Bot. Mag.*, 5946.)

Salvia rubescens (Ruddy Salvia). *Nat. ord.*, Labiatæ. *Linn. arr.*, Didynamia Monogynia.—A native of New Grenada. Shrub clothed with a pale hoary pubescence. Leaves ovate-cordate. Panicle studded with glandular viscid hairs. Flowers scarlet. —(*Bot. Mag.*, 5947.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Proceed with trenching, draining, and all alterations suggested previously for the ground. *Asparagus*, make a bed to succeed that in use, and on fine days draw off the lights to allow the heads to acquire their natural flavour and colour. Plant *Early Mazagan Beans* in a warm situation. Protect *Lettuces* in bad weather, but expose them freely on all other occasions. Sow for an early crop. Prepare horse droppings for *Mushroom* beds to succeed such as may soon become exhausted. Continue the introduction of *Rhubarb* and *Sea-kale* into warmth, to obtain successions of them as plants in use become worn-out. A few Strawberries may now be pushed forward, but do not drive them too fast, or the blossoms are apt to become "blind." Those in frames for succession should have plenty of air in the daytime during mild weather, but at night the lights should be put on in order to secure them against frost.

FRUIT GARDEN.

While the weather keeps mild new fruit trees may be planted; and where old trees, too, are not growing well a portion of the soil may be carefully removed from their roots and replaced by better material. Old gardens are often crowded with fruit trees, and since light and air are required more particularly than shade for the important products of the garden, take measures for removing all that are objectionable in this respect. The present is an excellent time for eradicating insects, especially those of the scale family. Where the young wood has become firm, the best of all appliances for this purpose are the sponge and syringe, with water from 110° to 130° and soft soap. Let every tie be unfastened, as these are their favourite hiding-places during winter, and where wire trellises are used they should also be thoroughly washed with this mixture.

FLOWER GARDEN.

Dig and supply flower beds with fresh soil, attend to the edgings of your walks and beds, reset flints, repair Box edgings, and rake wormcasts from your lawns with a daisy-rake. Where grass has failed under trees in the pleasure ground, rake-in strong manure, or apply manure water to prepare the soil for grass seeds, to be sown later in the season. Collect all sorts of soils, and store-up as many leaves as possible. Owing to the late mild weather Polyanthuses are throwing-up trusses of flowers. This is not a matter of so much importance in seedlings as in the varieties retained for exhibition. When the plant is strong it often happens that several trusses will show themselves at once, in which case it will be better to remove them and run the chance of having a side bloom that will often prove most excellent. These flowers, if in frames, should be protected from severe frost, and even those in the open border, though not so liable to suffer, will be better for a few fir branches, 12 or 18 inches long, stuck in the bed at intervals. There are great opportunities for improvement open in this class of flowers, and we trust that our readers generally will during the coming spring endeavour to hybridise and seed those nearest to the standard of perfection—rotundity of outline added to correctness of marking and beauty of colour. Our continental friends have done much more than our own florists in raising fresh varieties, but their energies have been directed to obtaining a diversity of colour without reference to form. Keep Auriculas from drip. Being alpine in their character, the close confinement of a frame is wholly unsuitable for them, and they therefore require all the air possible. Seed may be sown now in a cold frame, but covered very slightly, and when the frames are infested with woodlice we would advise a covering of clean and sweet moss, which keeps the surface secure from the changes of temperature, and will be of service to the germinating plants. It may be gradually removed as the young plants spring up. Tulips will only require keeping from severe frosts. Carnations and Picotees should have abundance of air, and the amateur will

do well to secure some of the best varieties early in the spring, in order that he may be enabled to raise seedlings worthy of his name. Dahlias may be started in moist heat where a great stock is required.

GREENHOUSE AND CONSERVATORY.

While the weather continues mild and fine, allow the plants in these structures the full benefit of it by admitting abundance of air, and fumigate on the first appearance of green fly, to which the late mild weather has been particularly favourable. See that the worms do not remain in quiet possession of their lodging in pots, and remedy any defects that exist in the drainage of these. We are inclined to recommend an increased and more general use of peat for ordinary potting. The best is found in old woods, and is preferable to strong, loamy, and rich soils, which we believe are too much employed. In the majority of cases the object required is not a plant grown to a large size, but a small compact specimen exhibiting the best characteristics of the plant. A few of the most advanced Azaleas, intended for blooming early, may now be planted where they can have a temperature of from 50° to 55°. Water carefully when necessary, and in mild weather ventilate freely. Some of the Camellias will now be in flower, so water must be liberally supplied, and air given tolerably freely during fine weather. Cinerarias will require careful attention in the way of watering.. Do not place them so close together as to touch one another, and be sure to keep them secure from frost. Chinese Primroses in bloom should be introduced into the greenhouse or conservatory, and others brought on to succeed them as their beauty fades ; but take care not to let them suffer from want of water. Jasminum nudiflorum—the bright yellow Primrose-like blossoms of this hardy Jasmine have such a cheerful look at this time of the year, when flowers are scarce, that a few plants of it should always be kept in pots for in-door decoration with green-leaved plants. Pelargoniums intended for flowering in May should be placed as near the glass as possible, and have a temperature of about 50° at night, though for the later-blooming plants it should not be above 40°. Solanum capsicastrum, together with Solanum pseudo-capsicum, and other sorts bearing small, round, bright-coloured fruit, are very useful at this season for purposes of decoration. See, therefore, that these in conspicuous situations do not suffer from want of water, especially if unavoidably placed in the neighbourhood of hot pipes.

STOVE.

Still be cautious in the application of more heat, as it is far better, the season being young, that plants should start somewhat later with a free growth, than make a premature and stunted one. Take every care that a due proportion of moisture is maintained in the atmosphere. Although the majority of Orchids require to be very dry at the root during the rest season, yet they, nevertheless, enjoy and require a somewhat moist atmosphere, more especially if in a state of constant and lively motion.

FORCING PIT.

The flowering of the Dutch bulbs, as Hyacinths, &c., is a most interesting part of the gardener's art. Some prepare to commence forcing them the moment they are purchased, or nearly so, but this can never answer, as it appears that in all cases several weeks of root action are necessary before the application of heat. When their pots or glasses are full of roots, then, and then only, can forcing really take place with advantage. Much care is necessary in removing them from the plunging material, as if they are suddenly exposed to light a premature development will be the consequence. They should be placed in a somewhat dark part of the stove for a few days, and abundance of atmospheric moisture provided. Continue to introduce flowering plants to the forcing pit. The dwarf-flowering Oranges might be more generally forced, as under such treatment they may be easily covered with their fragrant blossoms. Keep-up successions of Azaleas, Rhododendrons, Kalmias, Daphnes, Eparises, Roses, Lilies, Deutzias, &c. Let the forcing pit be supplied as the plants are taken from it. Bottom heat is of great assistance in advancing plants.—W. KEANE.

DOINGS OF THE LAST WEEK.

FRUIT DEPARTMENT.

GRAPES will set better without sun than Peaches. The present weather is dreadful for the latter. All that can be done is to maintain a temperature some 5°–10° lower than in sunny summer weather, and give plenty of air on mild days. Strawberries should be carefully watered, so that the soil may be neither too dry nor too moist. All who contemplate setting vineries and Peach houses in action, should see that the roots, if out of doors, are protected from cold and excessive moisture.

ORNAMENTAL DEPARTMENT.

All soil for potting should be well aërated and warmed before being used. The ball of any plant that is to be transferred to another pot should be well soaked with tepid water, allowed to stand before being finally moved, and should receive an additional watering after being potted. All plants taken from a warm sheltered place should be returned to it as soon as possible.

Acacias, although generally suitable for a cool house, are subject to being encrusted with a white scale insect. In such thick-foliaged kinds as A. armata and grandis, where washing the insects off is out of the question, the best remedies are glue water, or water thickened with clay. The plant is syringed with the latter, and placed aside to dry. After this the clay, carrying the insects with it, can be rubbed off in flakes by drawing the hand over the branches. The insect is, however, difficult to eradicate completely.

Azaleas.—On these insects, and especially thrips, must be looked for. Smoke them repeatedly and moderately with tobacco, wash well with weak soft-soap water, and afterwards with clear water, it being in both cases about the temperature of 100°. This can only be done when the plants are out of flower.

Camellias.—Keep these well drained, and apply a cool solution of water and cow dung. If the buds swell early they do not require forcing in spring and early summer.

Calceolarias.—Keep moist, cool, and airy if you wish to save tobacco-fumigating. Large-flowering herbaceous kinds which it is desirable to have in large plants, may have a little more heat at the risk of inducing green fly. The benefit of a somewhat low temperature for keeping plants free of insects is not yet thoroughly understood.

Cinerarias.—When they are in bloom, or opening their bloom, a more airy place and a slight rise in the temperature are desirable. Dryness at the roots is very injurious to them.

Daphnes.—The common or pink Indian kinds do best budded or grafted on the Spurge Daphne, and treated as Camellias. They must not be dry when in bloom. What can be more splendid than their rich Violet-like odour?

Ericas.—The winter-blooming kinds are now truly valuable, and may stand opposite the front-air openings. Give enough of water at a time to reach every fibre, and then wait until the surface of the soil is becoming dry. Tap the pot to see if it rings clear before you give it more water. See what was said lately about keeping water from the stem and collar of the plants. This more especially applies to this tribe and the

Epacris, though it is generally applicable. Epacrises will stand a good deal of direct air, but they will flourish with less than the Ericas, and are more suitable to a mixed house, as they never or rarely are troubled with mildrew.

Fuchsias, if now beginning to break, should receive what little pruning they need, and ere long be repotted, so that with the fresh growth there will be fresh rooting in fresh soil. After growth commences the plants must have the benefit of the light; use loamy, moderately rich soil, with surface-dressings and manure waterings.

Ferns.—From now is a good time for dividing and potting. Even the best and most tender of our hardy Ferns do all the better for the protection of a cool house. Even those from warm tropical countries will often flourish as well in a comparatively low temperature of from 55° to 60° in winter and early spring. They are less subject to the attack of thrips or other insects. Ferns of all kinds are rather impatient even of smoking, unless given very mildly. Weak washings with soft-soap water, followed in a day or so with clean water, both fully 100° in temperature, are safer than smoking. Fresh painting of woodwork and water pipes, and placing sulphur on hot-water pipes above 160° in temperature, will often injure the young fronds. A close atmosphere and a moderate temperature, with a fair amount of vapour, will suit the most of them better than a warmer and more airy atmosphere.

Geraniums, or rather Pelargoniums, with the exception of the Scarlets that are in bloom and need plenty of water, should be kept dry rather than wet. Florists' Pelargoniums should have a medium state of moisture, and be frequently rung to judge of the state of the soil. The most forward have been

potted into larger pots, and will receive no more stopping; but a second lot has been left unstopped to come in after the first, and other lots have been stopped to come in later. Small plants of last season have also been repotted, and the terminal buds nipped out. This, in many cases, is much better than taking away the points of shoots, as there is less check given, and it is not advisable to give any plant two checks at once. It is well to defer the picking-out of the buds for a week or so after repotting. We potted singly those florists' Pelargoniums, that had stood thickly in cutting pots during the winter.

Cyclamens showing bloom freely will now require a fair amount of water, and an airy sunny position. Large old plants are still a great treat, but they will become less so when the practice of sowing in the spring and blooming the plants from this sowing in the following winter becomes more general.

Violets.—We wished we had put more under protection. Those out of doors, owing to the frost and so much wet, have not yielded their usual crops, but we shall get the usual supply when the weather is better. Meanwhile we should have been badly off if we had nothing but those out of doors to go to. All kinds, if potted early in the autumn, bloom well in windows or anywhere under glass where severe frost is excluded.

Bulbs coming on need a good deal of water, and those plunged in a hotbed are lifted out and gradually hardened before being taken to house or window.—R. F.

TRADE CATALOGUES RECEIVED.

R. Parker, Exotic Nursery, Tooting, Surrey.—*Catalogue of Agricultural, Flower, and Vegetable Seeds, Fruit Trees, &c.*

W. Cutbush & Son, Highgate, London, N.—*Catalogue of Select Vegetable, Flower, and Farm Seeds.*

T. Bunyard & Sons, Maidstone, Ashford, and Allington.—*Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Hogg & Wood, Coldstream and Dunse, N.B.—*Spring Catalogue of Vegetable and Flower Seeds, &c.*

Little & Ballantyne, Carlisle.—*Catalogue of Forest and Ornamental Trees, Shrubs, Fruit Trees, &c.*

James Dickson & Sons, Newton Nurseries, and 102, Eastgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds.—List of Gladiolus.*

Charles H. Dickson, 23, Market Place, Manchester.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*

J. Scott, Yeovil, Somerset, and Merriott, Crewkerne.—*Catalogue of Seeds for the Kitchen Garden, Flower Garden, and Farm.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds, &c.*

W. Rollisson & Sons, Tooting, London.—*General Seed Catalogue, and List of Seeds of Subtropical Plants.*

TO CORRESPONDENTS.

VINE CULTURE—BLACK GRAPES (*A Subscriber*).—The best Black Grapes are Black Hamburgh, Black Muscat of Alexandria, Black Prince, Madresfield Court Black, Lady Downe's, and Alicante. For your other questions on culture we refer you to one of our numbers of last year, No. 553, page 331.

PLANTING ESPALIERS—PEARS ON QUINCE (*Ireland*).—Pears on the Quince and Apples on the Paradise stock, trained to espaliers, should be planted from 12 to 15 feet apart. Of the sorts you name, Jargonelle, Beurré d'Amanlis, and Louise Bonne of Jersey do well on the Quince. We do not know whether the others you name will succeed. The following are recommended: Williams's Bon Chrétien, Beurré Superfin, Doyenné du Comice, Beurre Hardy, and Winter Nelis.

SUGGESTIONS (*W. Jenkinson*).—Thanks for your suggestions.

GARDEN PLAN (*J. Watson*).—We cannot furnish plans, we only criticise those proposed. In "Garden Plans," which you can have free by post from our office for 5*s.* 4*d.*, there are numerous drawings of beds, borders, &c., how to plant them, and how to cultivate the plants.

QUESTIONS (*R. C. W. S.*).—Any questions you send will receive the best replies we can obtain. We make no charge.

COMPOST FOR VINE BORDER (*An Old Subscriber*).—The very best materials for an outside Vine border is turfy loam from an old pasture. To every five cartloads of this add one hundredweight of crushed bones. Should the loam be of a heavy nature, add one cartload of mortar rubbish to every ten cartloads of loam.

LEMON TREES NOT FRUITING (*Cleveland*).—Your Lemon trees are, no doubt, seedlings. They require the same treatment as Orange trees, but being of a very much more robust growth they are much longer in coming into bearing. Do not repot if the plants are in good health, and they will soon form fruitful spurs.

RIBBON BORDER (*A Beginner*).—We do not plant borders; but with a row of standard Roses in the centre, you cannot, unless you use very small plants, have four rows all round—that is, eight rows besides the Roses in a 6*8*-inch-wide border. We would sow at the end of February Perilla, use that for the centre row in the same line as the Rose stems and between them, then a band of yellow Calceolarias, next a band of Tom Thumb, and an edging all round of a mixture of white Cerastium and Lobelia Trentham Blue. If you had cuttings, the Iresine Lindeni would be better than the Perilla. The centre filled would give relief, and then three rows round would be ample.

PLANTING WALL TREES—SOAPSUDS FOR TREES (*T. H. T.*).—You may plant the wall as proposed, but on the principle that the standards are to be pruned-in to give the dwarfs room, as two dwarf Peaches against a wall will soon cover 24 feet in length unless the roots are curbed or pruned. In that part which the sun leaves at noon, you might, as respects fruit, grow Plums and Cherries very fairly. A little soda in your soapsuds will do no harm in watering at the roots. Such a mixture may also be used for syringing trees freely when they are in a dormant state. When in full leaf we prefer weak soap water that has not been used for washing and other purposes.

TREES FOR BANK WITH ASHES FOR SUBSOIL (*Sunny*).—On a similar kind of bank we have found the Austrian Pine and Elm thrive, with Cotoneaster microphylla and Ivy for undergrowth. If the ashes are in a thick layer—say 3 feet or more—and if there is only a thin layer of soil, your chance of getting anything to grow is extremely small.

AZALEA FLOWERS SMALL (*St. Honori*).—Forcing is no doubt the cause of the flowers being small. If the plants had been brought forward less rapidly the flowers would have been larger. You might have increased the size of the flowers by giving a little weak liquid manure two or three times a-week. Having had the plants in bloom at Christmas, it is not remarkable that the flowers were small. Caladiums to winter safely require a temperature of from 60° to 65°, and cannot be kept satisfactorily in a greenhouse. The roots are much better left in the soil—in fact, in the pots, and should be set on a floor or any place that will communicate to the pots a little dampness. If they must be kept in a dry position, give a sprinkling from a syringe overhead once a-week. This keeps the rhizomes plump, and prevents their becoming farinaceous and decaying when watering is resorted to to induce fresh growth.

SEWAGE (*T. H.*).—We can hardly advise you about your tank. Our impression is, that the water from the scullery, washhouse, and slops from bedrooms with merely the water that falls from a washhouse to dilute it, will, as a rule, be too strong to water Vines in pots with. We have used common house sewage for such purposes, but then there was a considerable amount of tolerably clear water mixed with it. It is much safer to give three clear weak manure waterings than too strong a one. Try it on Cabbages and Cauliflowers, and if they suit them, give it to the Vines considerably weaker. It would be an advantage if your tank were divided so as to have one part for sewage and the other for roof water. Though we use such sewage ourselves, we always try and regulate its strength according to the fitness of the plants for receiving it. *Liquid Manure.*—If you have such a difficulty in getting liquid manure, surface-dressing the pots would answer as well, if you are afraid of the strength. The safest and cleanest way would be to scatter over the surface of a 15-inch pot about 2 ozs. of superphosphate of lime, and repeat the operation in two or three weeks. If guano is resorted to, use a quarter of an ounce to a pot at a time. A half-inch dressing of horse droppings after it has lain for a week fermenting in a heap so as to have just lost its rankness, is much relished by Vines, and acts as a mulching, rendering the necessity of watering less frequent.

SOOT WATER (*Idem*).—Clear soot water is a good liquid manure for Vines and every plant that does not prefer a cooler manure, as Azaleas and Cinerarias. A bushel of good dry soot will be enough for from 100 to 150 gallons of water. We like to have it without dust and lumps, and as clear as the best brandy. To secure this place the soot in a tub or barrel, and use only a little water at a time until you have beaten it all up into a thick paste, then mix it with the water, and add one large shovelful of quicklime; on the forenoon of the day after remove the surface scum, and on the following day there will be a powerful clear liquid manure. For tender plants it would require to be reduced. Such clear liquid is invaluable for syringing, but if you have a doubt, use it weak. The use of such water overhead will save many a tobacco-fumigating.

STAGE OR BED FOR ORCHIDS AND STOVE PLANTS (*A Young Beginner*).—There can be no doubt that some plants do better with a little bottom heat, but in your case we would be perfectly satisfied with the iron-grated platform, and evaporating-pans on the flow-pipes beneath them. There is a double suggestion we would make. As the iron-grating is there, it would be better to galvanise it, and for tender plants you might have thin round pieces of wood or slate to set the pots on, as iron is apt to get too hot or too cold for some plants. To do this well you must add two more 3-inch pipes in the pathway. If ever you should make a sort of chambers in your two pits, which you could easily do even now by having sufficient rough cocoa-nut refuse on the grating to partly plunge the pots in, then we would recommend two pipes with evaporating pans all round the sides and end of the house above the grating platforms. With your present arrangement and the addition of pipes, you may do wonders. It is a mistake to limit piping with a view to economy, as so much more firing is wanted, and because heat from very warm pipes is always unhealthy. If you wish to give a little bottom heat, all that you need do is to shut each pair of your pit with a wooden division, and use above cocoa-nut fibre, which does not harbour woodlice so much as tan. Mind, however, it is one of the best non-conductors, and, therefore, you should use it chiefly for keeping the heat about the plants. Clean sand would answer as well if you covered the grating with slates to prevent its falling through. If you wished to attempt growing some beautiful plants that require a high temperature and an additionally moist atmosphere, we would thus enclose a part of one of the pits, and place a little box over it covered with glass. The glass is easily moved and reversed, the lower side being placed uppermost, and proves exceedingly useful in such small houses. With the extra piping, however, you may do very well without these additions. Phalænopsis grandiflora does best on a log of soft wood, as the Calabash tree, or even on wood covered with cork fixed with a little sphagnum.

LAURUSTINUS NOT FLOWERING (*Black Edge*).—The sprig you enclosed to us is not injured by frost, and the flower-buds would have expanded when the weather became sufficiently mild. They are late in flowering owing to the cold and wet season. The cause of the wall plants in pots hancing their heads, we should say is injury from the late November frosts. Are the pots protected? If not, it is probable the roots have perished. The pots should be plunged in the ground over the rim, or be protected with ashes or litter in winter. All you can do is to protect the plants with mats in cold weather. What you want is mild weather. The Hollies cast their leaves in consequence of their removal, chance of position, and the early frost. You can do nothing to prevent such occurrences.

URCEOLINA AUREA AFTER FLOWERING (*G. H.*).—Keep it moderately supplied with water, give it a light airy position, and continue this treatment until about April; then after reducing the supply of water, keep the plant dry for three months, when it may be again started into growth. The *Aphelandra aurantiaca Roezlii* done flowering should be kept dry, but not so much so as to cause the leaves to shrivel, and in about three weeks it should be cut-

in; or if it is only a young plant, merely remove the flowering part, and when it has made shoots a few inches long repot it, and encourage growth with plenty of moisture and heat. Having secured a good growth expose the plant fully to light and air to secure the ripening of the wood. It is one of the finest of winter-flowering plants, and those requiring plants for table decoration ought to grow it in quantity. We can only account for Adiantum farleyense losing its fronds by the dry heat, which it does not like. Afford more moisture, and in the temperature you name it ought to thrive, and we have no doubt it will do so in spring. Magnolia Campbelli is deciduous, losing its leaves in winter it should flower in April from the ends of the branches whilst the tree is leafless. Being from Bhotan, at an elevation of from 8000 to 10,000 feet, it certainly cannot need more than a cool greenhouse, and is probably quite hardy. We should try it in a sheltered spot, for it attains the dimensions of a large tree, and so needs more room than can be accorded in an ordinary greenhouse.

FERNS IN CASE NOT THRIVING (*G. B. A.*).—The depth of soil is too little, it ought to be 3 inches, and the tray in which it is held should be perforated at the bottom with holes a quarter of an inch in diameter at 3 inches apart, and beneath this should be a cavity of at least half an inch to allow of the water draining from the tray above. This receptacle should be watertight, and have a tap at one end to let off the water occasionally. If you remedy the want of drainage, place about half an inch of crocks at the bottom of the tray for the soil, so as to permit of the free passage of water, and give twice the depth of soil you have, we think your plants will thrive. A blind between the sun and the Fern case will prevent the light proving too powerful for Ferns.

JOINTS OF HOT-WATER PIPES (*Agri*).—The mode you refer to is advertised as answering, and some acquaintances of ours say it succeeds, especially where there is not much pressure. Unfortunately we have not tried it ourselves, and what little we have seen of it would deter us from doing so. A gentleman told us the other day that a certain house had its pipes so done, and half the joints were leaking. Notwithstanding this we are assured that it answers in many places, and therefore we would not prejudice anyone against it. Were we doing the work ourselves we would make the joints tight with the usual hempen yarn made firm with a little red lead. All iron-filing and sal-ammoniac joints are just liable to expand and crack if not carefully made. The secret is not to fill the joints too full. We have had joints that cracked in a year or two. We have known others where the socket was not filled to the outside that stood the wear of some thirty years, and are as good as the day they were made.

TANK AND PIPE-HEATING (*Idem*).—We fear we do not quite understand you. You speak of having a cement tank in the centre of the vinery, and the four fresh pipes you are to add are to be used as a continuation and then as return-pipes to the boiler, and yet you also wish to work either tank or pipes, separately or combined, which would be next to impossible. Now these pipes strike us in reading your letter. First, if the vinery is not too wide and lofty, a cement tank 4½ feet wide, divided down the middle, with an opening at the farther end, a flow-pipe at one side and a return-pipe at the other, ought to be sufficient to heat a common vinery. We are supposing that the tank is 4 inches deep and covered with slate or iron. Second, what little practice we have had in this direction would lead us to hesitate before taking pipes in continuation from a tank 60 feet long, as, be the cause what it may, we have found that the circulation in such circumstances was very languid. If the tank was all flow and the pipes used as returns it would be different. On the whole, then, if we were adding these four times we would have the tank a little above the level of the highest pipes, would carry the circulation of the tank complete in itself as stated above, and take the flow-pipes either by a T-junction or direct from the boiler, rising a little towards the farthest end of the house. This end we would have a few inches below the level of the water in the tank, placing an open air-pipe there 3 or 4 feet in height, and would take the return on the same slope to the boiler. By a single valve on the flow-pipe for either two or three flow-pipes, and a similar valve on the flow-pipe to the tank, you can heat tank or pipes together or separately independently of each other. We do not see how otherwise you can attain your object. By this plan all is easy.

EFFECT ON PLANTS OF NEW PAINT (*Idem*).—Until the scent has thoroughly gone it will injure all tender foliage. In your case a little more fire heat and more air would be better, even if you have air on the top all night. The air will keep the budding Vines back, and ere long you will find the scent has gone. It would be advisable to leave a little air on at the top for a fortnight, even if you should have to use a few shovels more of coal. We speak experimentally here, as more than once we have had fine plants suffer severely when we have had to shut them too early against our judgment. Bear in mind, that a shock of fine weather at midsummer will do more to sweeten a newly painted house than a month will do at Christmas. As to painting hot-water pipes, there is a black paint generally used by tradesmen for this purpose. Dried linseed oil and lamp-black, or blue-black, make a good paint. In either case, however, the pipes should be heated and the house kept open, so as to get the fumes from the paint off before such tender plants as Ferns are placed in the house. Of course you know that tar paint is ruinous when placed on pipes.

SHRUBS FOR HEDGE (*Far West*).—We do not think Gorse would be suitable, as it requires an open situation, and in your shaded spot would grow too weakly to keep back intruders. We should plant Holly and Berberis Darwinii—two Hollies, and one Berberis per yard run; Thorn and Holly make a very good hedge if planted at the rate of five Thorns to one Holly per yard. Either of those combinations would answer your purpose. We would plant the ground as a shrubbery in such a position, for shrubs succeed better than flowering plants. We should have Rhododendrons, Chinese Arbor-Vitæ, Aucubas; Berberis Aquifolium, B. Darwinii, B. japonica, B. stenophylla; Tree Box; Cotoneaster microphylla, C. Simmonsii; Cydonia japonica; Euonymus japonicus, gold and silver-striped. Hollies, the gold and silver variegated, and plain-leaved, as Ilex Hodginsii; Common and Portugal Laurels; Laurustinus, common, and black-leaved; Phillyreas, Skimmia japonica, Yucca filamentosa and recurva, English and Irish Yew; Vinca elegantissima, Azalea pontica, Broom of sorts, Deutzia gracilis, Forsythia suspensa, Hypericum calycinum, Syringa, Ribes, Thorns, Weigelas, Lilacs, and Spiræas.

BALSAMS AND COCKSCOMBS TO FLOWER IN JULY (*An Amateur*).—April is soon enough to sow Balsam seed. We should sow early in the month in a sweet hotbed, with a temperature not below 60°. The pots should be near the glass; and when the seedlings can be handled, pot them singly in small pots, and so that the seed leaves may not be more than 2 inches above the surface. They should be continued in the hotbed, and be shifted into larger pots as the others become full of roots; and the nearer the plants can be kept to the glass without touching it, the stronger they will be. They should be placed lower in the soil at each potting, for the Balsam throws out roots all up the stem; but at the last potting the stem should be clear to within 1 inch of the seed leaves. We consider 9-inch pots sufficiently large. The buds should be picked off the main stem until there are buds on the side shoots. A light rich soil is most suitable. If the plants are likely to flower before you want them to do so, continue to pick off the buds, only you must have buds the size of peas a fortnight before you wish to have them in bloom. Cockscombs must be sown early in March, in a hothed of not less than 60°, and should be kept near the glass, potted singly when they are fit, and kept in small pots until the crowns show; then select the best, and grow them on keeping them near the glass, but not so as to touch it, affording a good temperature, moist atmosphere, and a moderate amount of air. Eight-inch pots are large enough. The Zonal Geraniums you have wintering in a room should be kept moderately dry up to March; then do any pruning required, but continue to removing irregularities of growth. After pruning, repot the plants, fine it to removing irregularities of growth. After pruning, repot the plants, taking away most of the old soil. Use pots that will just contain the roots. In May shift the plants into their blooming pots, grow them in cold frames after the middle of May, or out-doors, protecting the bloom from heavy rains. Ten bushels per acre will be a sufficient quantity to sow on Wheat; and it should be applied at the end of March or beginning of April.

NAMES OF FRUITS (*G. T. M.*).—Your Apple is Flower of Kent. (*W. K.*).—Your Apple is Reinette Grise. It is fit for dessert from November to April.

NAMES OF PLANTS (*Betchworth*).—Sparrmannia africana, a native of the Cape of Good Hope. It was introduced here in 1790, and is drawn and described in the sixth volume of the "Botanical Magazine." (*J. Batt*).—Habrothamnus fasciculatus. (*W. B. Hole*).—Sparrmannia africana, a native of the Cape. (*J. P.*).—Your Rhododendron is perfectly normal and presents nothing whatever unusual; it is merely breaking its leaf-buds. The other plant is Phytolacca purpurascens.

POULTRY, BEE AND PIGEON CHRONICLE.

A PLEA FOR JUDGES AT POULTRY SHOWS.

In trenching upon this delicate question I desire at once to say that it in no way interests me personally. I am not a poultry judge, nor have I ever suffered from incorrect judging, have only exhibited three or four times, may never exhibit again, and have never exhibited without being *decoré*. My voice is raised alike in the interests of judges, exhibitors, and managers of poultry shows. It is an unpleasant thing for a judge to have his judgment questioned, to an exhibitor to feel that he is wronged, to a committee to hear complaints; and yet I cannot see how in the present state of things this is to be avoided. A show is announced, some five hundred entries, perhaps, are made, and one judge is appointed—a man who knows his work (although I should be inclined to doubt the complete knowledge of one man in Pigeons and poultry). Well, let it be presumed he does. He is admitted to the room, he has three or four hours to decide on the various classes, to look at, examine, weigh the birds, and he has just half a minute to each pen. Now I ask, in the name of common sense, how is it possible for any man to do this? more especially when, as we, alas! hear too often in the columns of the Journal, trimming, and painting, and tricks of all kinds are practised by some exhibitors. And is it any wonder that the most glaring mistakes are made? I do not speak without book. We have had lately two shows in this county, one at A——, and the other at M——; at both of them a Mr. G—— exhibited a Dorking cockerel. The Judge was one of our most experienced poultry-fanciers, a name looked up to by everybody who knows anything of fowls. In the show at A—— this cockerel was very properly passed by—it had four toes; but, *mirabile dictu*, at M—— it obtained a first prize. Other cases of a similar character have come before me; but this is one upon which there can be no question, and so it will suffice to adduce it. Now I put it to the managers of shows whether they cannot make some alteration. Curtail the expenses in some way. Let no judge go single-handed, there ought always to be two, and give them less to do. The taste is so widely spread now, that I think it would not be difficult to obtain amateurs to act with professed judges, one in each division. Could there not be a conference held (as these are all the fashion now-a-days), of the secretaries of poultry shows to devise some plan for improving their management? Evidently something is wanted as to the changing of claimed birds, &c. In fact, there seems to me an amount of roguery connected with poultry-exhibiting, which, were it not that they appeared in your columns, I should not have credited. I have had much to do with flower shows, but the cases of dishonest showing that I have heard of or seen have been very few. Complaints very rarely find their way into the horticultural portion of the Journal, but how the Poultry Chronicle bristles with them! One is, alas! prepared to hear about cheating in horseracing and dealing, but that it should come in amongst

the poor cocks and hens is too bad. I believe one way in which it can be checked is by a more rigid system of judging; and I think all honest exhibitors will hail anything that tends to make exhibiting something different to what it now is.—D., *Deal*.

DORKINGS—HOW SHOULD FOWLS BE FED AT SHOWS?

Some few weeks back I received two letters from different quarters, each written in the same strain. "The Dorking cockerel of yours which I claimed at the Crystal Palace is dead," said one correspondent. "The two Dorking cockerels which I showed at the Crystal Palace are dead," said the other. "I have also heard that the cup cockerel, you will remember the grand black bird as sooty as the king of the sweeps may be supposed to be, is also dying." Here was a fine catalogue, but worse was to follow. I had been foolish enough to buy a pair of pullets which had won high honours at Birmingham, and gave £10 for the two, although I had birds at home nearly if not equally good. When they arrived I, of course, expected something grand; £10 will do a great many things. It will take you to Paris; keep you ten days there, and bring you back again. It will take you up the Rhine almost into Switzerland, and bring you home again with enough left to pay your railway fare first-class to your house if you only know how to manage matters. It will almost keep you in clothes for a year, if you are not too particular about the cut of your coat and the colour of your gloves. It will insure the payment of £500 after your death, if you will only begin in good time. In fact, £10 will do a vast deal more than most people imagine. Well, my precious pullets I found to be very dark (I had bought by deputy and desired dark birds), a very good match with very good feet, but their weight was nothing compared with what I have seen described in the "Journal," as neither of them weighed, I believe, over 7 lbs. Their light weight reminded me of a friend of mine who gave £10 for a first-prize cockerel (I think he was first) at the Crystal Palace, in 1870, and found when the bird arrived home that he weighed only 7¼ lbs. He, however, who deals in Dorkings must be prepared for any amount of disappointment, so that I was not much concerned. But, then, the wretched creatures would not eat! They were not actually roupy, but roup or something worse seemed certain to ensue. My careful henwife, however, fed them *nolens volens*, or more strictly speaking, *nolentes volentes*, with warm bread and milk, gin, port wine, and raw meat, so that they have survived to be highly commended at a large show, and adorn the triumph of others.

Now my chief purpose in writing this is to ask some of your learned correspondents to state what they consider the best method of feeding fowls at shows. I am told that at Birmingham they strew the pens with a quantity of sand, which is consequently mixed with their soft food, and so cannot do them much good. At a show recently where I happened to win two first prizes and a £5 5*s*. cup, I found the attendant feeding the birds in the most reckless and profuse manner, while this abominable sand was thrown down as at Birmingham and elsewhere. He seemed to know nothing of what was done at other shows, or what ought to be done, and I could not undertake to teach him. Some of your readers, however, are certain to have opinions on the subject. I, for one, should be glad to hear them.—A Winner of Four Cups.

THE ANNUAL SHOW OF PIGEONS

BY THE MEMBERS OF THE NATIONAL PERISTERONIC SOCIETY.

This was held on the 9th inst., in the tropical department of the Crystal Palace, and comprised nearly one thousand choice birds, and almost every variety. Pouters were not numerous, Mr. P. H. Jones being the only exhibitor. Almonds were many and good; the pen shown by Mr. Merck was deserving of special mention for the beautiful colour and the natural state in which the birds were shown, proving that it is not necessary to manipulate and deform the beak to produce a beautiful bird. Mr. Jayne and Mr. Ford, as may be supposed, showed splendid pairs of birds. Mr. Esden's Black Mottles were much admired, as were Mr. South's and Mr. Ford's Beards. Carriers were a fine show, including some magnificent birds from Messrs. Ord, Hedley, Greenfield, Martin, Tegetmeier (Blues), Feltham, W. B. Ford, of Weymouth, and Square, of Plymouth. Dragoons were a show in themselves, and it is quite impossible to do justice to this variety in a short article; nearly two hundred of this rapidly improving public favourite were penned, including splendid Yellows from Mr. F. Graham, of Birkenhead, and Mr. Betty; Reds, Blues, Whites, and Silvers from such well-known names as Tegetmeier, Jones Percivall, South, Martin, Feltham, Greenfield, and Jones. Barbs were well shown by Messrs. Hedley and Jones. Mr. Tegetmeier had a beautiful pen of Piping Pouters. English Owls were shown by Messrs. Esquilant and Jones, and the latter gentleman had two pairs of charming little foreigners, Blue and White. Mr. E. E. M. Royds, of Manchester, sent a pen of Jacobins, which fully sustained that gentleman's reputation. Mr. Jones had a beautiful pen of Black and Mottled Trumpeters, including two or three of great excellence. Mr. South and Mr. Jones had good pens of Turbits; Mr. Tegetmeier and Mr. H. Little a very fine collection of Antwerps, showing all the characteristics of this famous class of birds. Magpies, Nuns, and various other Toys were shown by Messrs. South, Jones Percivall, P. H. Jones, and others, and the Show may be described as fairly representing most of the usual varieties.

We are pleased to hear that the Society is very flourishing, several new members having been recently elected. The place of meeting now is the Covent Garden Hotel, King Street, Covent Garden, instead of the Freemasons' Tavern as heretofore.

BRISTOL POULTRY AND PIGEON SHOW.

Prior to the holding of this Show last week, a somewhat general opinion was expressed that the newly adopted rule of enforcing in all cases a twenty-shilling subscription, independent of entry fees, would so much limit the numbers at the Bristol Exhibition as to make it comparatively a failure compared with those shows that preceded it. We are very glad to say, that not only was there an entry of nearly a thousand pens, but also that a very strong feature of the Show was the general excellence of the birds on view; and the meeting was equally remarkable for the very few empty pens compared with those on former occasions. The result, therefore, appears to be this: the number of individual exhibitors is considerably lessened, but the quality of the birds shown in the aggregate is vastly improved. We may safely add that the Bifle Drill Hall is admirably calculated to show such specimens to the greatest advantage. The only drawback was that many of the very best pens of birds were quite overshown, and instances were not wanting in which first-class well-known birds could scarcely stand at all.

There was a very grand display of *Dorkings*, the principal winners being birds that had not been shown for many months past. Certainly one of the best collections of Buff and White *Cochins* ever seen were present, the hens being particularly fine, and also the younger birds of both sexes; but the old cocks were as yet barely through their moult. Dark *Brahmas* were exceedingly good, and there were also a few superior ones among the Light sort; but the falling-off in quality among the majority of these classes was very apparent. The *Spanish* classes were, as might be anticipated at Bristol, of first-rate character; and the whole of the *Game* fowls were equally worthy of the highest praise. Twenty-six pens of the best *Malays* we have seen for some years past were on view, and proved a very interesting portion of the collection. *Ducks*, *Turkeys*, and *Geese* were capital throughout; and the Buenos Ayrean class was as near perfection as possible. The Cayuga Ducks, shown was as near perfection as possible. The Cayuga Ducks, shown here as a novelty, have been generally known, and that for a long series of years past, in both Lancashire and Yorkshire. The Committee were evidently determined, individually, to pay every possible attention to the wants of the poultry exhibited, and they certainly left no cause for complaint by anyone. The meeting of 1872, therefore, augurs well to insure a long succession of similar annual reunions.

THE PIGEONS.

Once more in dear, dirty, interesting Bristol. Dear, because long known—not dear, certainly, in regard to purchases that can be made, for there is no cheaper shopping-place in England; dirty in summer often, in winter always; and interesting from its history and associations. Bristol and Clifton—curiously conjoined towns, Crissy-Millie fashion, but one dark, the other fair. This singular combination gives to Bristol a speciality. In its streets, unlike Bath streets, heavy-laden business waggons jostling against Clifton well-appointed carriages. It is a mingle of fashion and business all through. After a two-years absence I mark a great improvement the moment after I leave the station. Instead of crawling along narrow, ancient, ill-smelling Temple Street, there is a new, wide, straight, shaft-like street running direct from the station to the bridge, like Victoria Street, Westminster. This cuts through two or three narrow streets, up either end of which we peep in passing—a curious proof of the march of improvement. But what do I see there? A new spire in progress! Is it possible that can be St. Mary Redcliffe? 'Tis so, but the St. Mary Redcliffe of long association no more. Generations of Bristol boys have watched the broken or stunted spire as they sailed to make their fortune

from the harbour. Now a spick-and-span lofty spire, but not the St. Mary Redcliffe that all the world knew. Past Bridge Street—so named, perhaps, because it does not lead straight to the bridge, and past Broad Street—surely ironically so called, for it is narrow indeed.

Soon I reach the Rifle Drill Hall and hear its annual inhabitants. I dare say the worthy and gallant Bristol Volunteers would fight as well as their temporary guests, but they would certainly crow less. Involuntarily I exclaim with the circus clown of my youth, "Here we are again." Not a refined exclamation certainly, but it just describes one's feelings. All is just the same—the Hall the same, the pens the same. There comes Mr. Cambridge, the first to shake hands, looking just the same; there in his office pen in hand is Mr. Roué, as he always was; there the rest of the Committee; there in a glass case the gorgeous silver cups, three different kinds; there, not far off, is Mr. Rodhard and other well-known Bristol breeders of Spanish. But before going straight to the Pigeons let me compare last year's Show with this. Last year 1300 pens, this year 1000—only 300 fewer, owing to the one-pound subscription required. But "list, oh! list." Last year 440 exhibitors, this year only 167—a falling-off owing to said pound of 273. But clearly many exhibited under the name of one, as the comparatively small difference in the number of pens shows. There was no rule against this, so it was not absolutely unlawful, though not absolutely correct.

Now let me just say a word—a well-intentioned word—both to the Committee and the exhibitors. It is not right that every year a committee should lose money by a show. They give time, often precious; they give great labour, they show pluck and energy; but after all to have to put their hands into their pockets and pay out heavy sums is—well, is too much to expect, indeed what ought not to be. Perhaps, as the one-pound subscription was so much objected to, a graduated scale would answer and be less disliked; say, for instance, the exhibitor of one pen pay as entry money 15*s*., of two pens 1*u*s., and then if more than two a lower sum for each pen. Perhaps this plan would answer. But no more of this, but to the far pleasanter work of inspecting the Pigeons.

Carriers (Blue or White).—The word white seemed to be unnecessary, as no white birds appeared, but seven pens contested for the cup, which was won by pen 846, containing a pair of Mr. Yardley's birds, the cock too wide in the skull, and the blue by no means free from a smoky tinge. Mr. Ord showed in pen 840 a well-matched pair unnoticed. Mr. Fulton's (841), were a grand pair and commended. Money prizes in this class there were none.

Carriers (Black or Dun).—Sixteen pens. First and cup, Mr. Fulton's Black, he also second. Mr. Ord's Duns, pen 849, were a nice pair, and the hen in his pen 854 was very good. Also the hen in Mr. Maynard's commended pen was good.

Pouter Cocks (Any colour).—This was deservedly marked "An excellent class." The cup bird, Black Pied, is thicker than I like. Mr. Dew's highly commended, pen 870, is a remarkably neat bird, but the gem of the whole class was Mr. Fulton's very highly commended Yellow Pied, which reminded me of the Glasgow Yellows.

Pouter Hens (Any colour).—First prize, Red and somewhat coarse. Mr. Gresham's very highly commended, a neat Blue and better to my mind, and no doubt to his, than the bird with which he won second.

Almond Tumblers.—A good class, and very evenly good.

Jacobins (Any colour).—The fault of this class was the height of the hood from the head; some looked, instead of neat and close, ragged and wide. Mr. Haansbergen showed both a White pair and also a Black pair, both a treat as to colour, and good too. A treat as to colour, for the Reds were so predominant, and the Whites were unusually good.

Barbs (Any colour).—This was certainly a good class. Both the first and second-prize birds were excellent, and must have puzzled the Judges, but the very highly commended Duns were to my mind as good as either, but their condition was against them. I asked the Committee to let these birds as well as the Carriers have saucers for their food, as they cannot see grains of food on the ground.

Fantails.—A good class. The cup-birds were dirty in the extreme. The same owner, Mr. Yardley, showed a good pair of Blues. Out of the ten pens six were noticed, and the first-prize birds at Southampton and Wilts were unnoticed. This a proof of the great merit of the class.

Trumpeters.—Four pens only, and good; but Mr. Horner's second-prize birds I preferred to those of his which took first.

English Owls.—Very few, and among them one pair, pen 927, which were not English. In the first-prize pen the cock is the best.

Nuns.—Numerous. The first-prize birds well deserved their place, they were Mr. Horner's. Mr. Haansbergen had a pair of Yellows commended. It is pleasant to see that colour, as all the rest were Blacks.

Turbits.—Surely in this class condition must have ruled the Judge's mind, as both prize pens contained long-faced birds. Mr. Roper's very highly commended were very good, also pen No. 945.

Tumblers (Any other variety).—Mr. Fielding's cup birds were far from clean. The second-prize birds were real Black and White, clean and good.

Dragoons (Any colour).—A large and good class, there being fourteen pens, and not Carrier-like, but thorough Dragoons. The first prize, Blue; second, Yellow, but not so good as the same owner's pen, No. 974. But Mr. Graham may well be proud of both pens.

Antwerps.—Marked "A very good class," but I own I am utterly unable to see why they were so denominated, save, perhaps, as they exhibited every variety of head, from the lean and mousey, to the thick and Barb-like. There seems to me to need a standard shape in this class. The one figured in this Journal, contributed by the Birmingham Columbarian Society, being evidently not followed.

Any other Distinct Variety.—A pretty pair of African Owls first; a pair of Maltese, more valued by the Judge than their owner, as they were put at a low price, second. A very pretty pair of Frillbacks were shown by Mr. Arkwright; a well-matched pair of Archangels by Mr. Yardley; and a good pair of Red Magpies by Mr. Haansbergen. Also, I must notice a pretty pair of Ice by Mr. Dawson. This is a class which deserves encouragement more than it gets, for to very many visitors it is the most attractive of any, and I would there had been thirty pens instead of ten.

I do not know whether there is much to add. I would advise the Committee to have cage birds next year. The late census proved there were more ladies in proportion to gentlemen in Clifton than in any other place in England, and ladies are proverbial for their love of cage pets. I mentioned the advantage in having the food in saucers, or better still, in tins, such as contain water, as it would not be wasted by the birds; and the heavy-wattled varieties would be sure not to starve. The water-tins might also be hooked up higher, so that the water would be kept purer. The Drill Hall is, as is well known, one of the best exhibition-rooms in England, the Committee most energetic and persevering, and I hope that every year they will lose less and less, or better still, not lose at all. We, in the west of England, could not do without the Bristol Show, and may a long reign of success be in store for it.—Wiltshire Rector.

The new regulation put in force by our Committee had the effect of thinning the ranks of Hamburgh exhibitors immensely, as your readers will see by the annexed figures:—

	Pens in 1871.		1872.
Gold-spangled	39	..	21
Silver-spangled	29	..	11
Gold-pencilled	47	..	19
Silver-pencilled	21	..	16
Blacks	14	..	15
	150		82

About one-half the entries of last year. We missed the names of the majority of our leading Hamburgh breeders. Buckley, Ogden, May, Hyde, and Walters did not send their spangles; Mann, Pickles, and Ashton their Silver-pencils; Preston, Tickner, Speakman, and Smith their Golds; nor Kilvert, Sidgwick, and Marlor their Blacks. Hence the disappointment of Hamburgh breeders who visited the Show.

If the entries were few, the quality as a whole was also very much below that of last year with one exception, the Black Hamburgh cocks. Mr. Sergeantson's first and second-prize pens contained unquestionably the best birds of the Show (I am speaking of Hamburghs only). And why the cup allotted to Pencilled and Blacks went to Mr. Parsons instead of Mr. Sergeantson is an enigma not easy to be solved, for the Golden cockerel in point of tail, earlobes, carriage, and condition would not bear comparison with the Black. The rev. gentleman's hens were very small, and gave me the melancholy foreboding of a possibility of this new and beautiful variety dwindling down to the level of Pencilleds in point of size. Pray, Messrs. Judges, if you admire, and very properly, lustre of plumage, neat comb, beautiful ears, and a sprightly carriage, do not forget size! In the Gold-pencilled cocks, the ingenuity of a Yorkshire exhibitor was somewhat freely commented upon. Every breeder of this variety knows how to appreciate beautifully-arched sickle feathers. What Nature here lacked Art supplied, the barrel of the long sickle feathers of the cockerel in question being very dexterously bent (a friend of mine very wickedly suggested with a curling iron), to give the desired sweep! The Gold-pencilleds throughout lacked the beautiful ground colour which has been so often insisted upon, and justly so, in your columns. In other respects the Pencilled hens were fair as a whole, and I was glad that the Judges recognised the value of a pencilled breast, even at the expense of a cloudy hackle, by giving the cup to Mr. Bloodworth's hens. The Silver-pencilled cocks were the worst class in the Show; while in the hens the

fine pencilling but rather dark necks of the second and third pens had to give way to the clear hackle of Mr. Beldon's pair. Spangles were a long way behind those of last year as a whole, although the prize birds deserved their positions.

In conclusion, Mr. Editor, allow me on behalf of a large number of amateurs, to express the hope that the Committee of the Bristol and Clifton Show will not repeat their blunder of 1872. If a preliminary subscription be considered necessary, let it be on the same footing as Birmingham, four pens for every 32s., instead of two pens for the same amount. Last year we had 433 exhibitors, this year 163. I leave this fact to speak for itself.—P.

It must now be clear to the Committee of the Bristol Show that their obnoxious 20s. subscription is not at all relished or supported by the exhibitors in general, as evidenced by the number of exhibitors in 1871, against those of 1872. They may say, We have not incurred any pecuniary loss by the alteration, thanks to large exhibitors (or at least forced large exhibitors); but the fact that there are only 163 exhibitors this year against 426 last year speaks for itself, and will caution the Committee that they must study the small as well as the large exhibitor.

I trust the Committee will endeavour to make some alteration for the better so that this hitherto first-class Show may redeem its lost supporters. It is not to be expected that the Committee can carry on the Show at a loss, neither would any one that had the least love for the fancy expect them to do so, but let all be placed on the same fair footing, whether great or small exhibitors, and then the Committee will be large and successfully supported.—WELL-WISHER.

KENDAL POULTRY SHOW.

THE following awards were made at this Show, held on the 11th, 12th, and 13th inst:—

GAME (White and Piles).—1, C. W. Brierley, Middleton. 2, — Thompson, Higher Greaves, Lancaster. 3, F. Sales, Crowle, Doncaster.

GAME (Black-breasted and other Reds).—1, H. M. Julian, Hull. 2, C. W. Brierley. 3, T. Mason, Green Acre, Lancaster. *hc*, F. Sales; J. Chester, High Town, Nantwich; J. Wilson, Rigmaden, Kirkby Lonsdale. *c*, Miss Graham, Kendal. *Chickens.*—1, C. W. Brierley. 2, G. F. Ward, Wrenbury, Nantwich. 3, E. Aykroyd, Eccleshill, Leeds. *hc*, J. Jones, Nantwich; T. Burgess, Whitchurch, Salop; J. Chester.

GAME (Any other variety).—1, — Brierley. 2, — Thompson. 3, F. Sales. *hc*, H. M. Julian, Hull; J. B. Cockerton, Cartmell Fell; E. Winwood, Worcester. *c*, H. M. Julian, Hull. *Hen.*—1, C. W. Brierley. 2, E. Wells, Kendal. 3, T. Mason, Lancaster. *hc*, G. F. Ward, Wrenbury, Nantwich; — Brierley.

GAME.—*Cock.*—1, G. F. Ward, Sprosting Wood, Wrenbury. 2, H. M. Julian, Hull. 3, J. Bowness, Manche-ter. *hc*, G. Clements, Birmingham; — Brierley. *Cockerel.*—1 and Cup, — Brierley. 2, J. O. Rigg, Ulverston. 3, W. Barnes, Blencathasset, Aspatria. *hc*, J. Jones, Nantwich; T. Burgess, Whitchurch; T. Mason, Lancaster; J. Mashiter, Ulverston.

GAME BANTAMS.—*Cock.*—1, T. Sharples, Forest Bank, Rawtenstall. 2, G. Todd, Sunderland. 3, J. Oldfield, Bradford. *hc*, J. W. Morris, Rochdale; W. Caton, Kirkby Lonsdale; — Noble, Staincliffe, Dewsbury; H. J. Nicholson, Cumberland; J. W. Brockbank, Kirksanton; A. Ainslie, Ulverston; T. Barker, Bornley; J. R. Robinson, Sunderland; W. Adams, St. Clements.

GAME BANTAMS (Black-breasted and other Reds).—Cup and 2, T. Sharples, Rawtenstall. 3, G. Todd. *hc*, — Noble, Staincliffe; H. J. Nicholson; J. S. Butler, Poulton-le-Fylde; J. R. Robinson.

GAME BANTAMS (Any other variety).—1, G. Todd. 2, — Sharples. 3, Bellingham & Hall, Burnley. *hc*, Rev. C. J. P. Keene, Hulsall. *c*, J. Goth, Windermere.

BANTAMS (Any other variety except Game).—1, J. Sichel, Timperley (Pekin). 2 and 3, — Leno, Dunstable (Laced). *hc*, J. Walker, Birstwith, Ripley (White); W. W. Boulton, Beverley (Cuckoo); R. H. Ashton, Mottram (Black); — Walker, Halifax (Black); E. Blackwell, Bolton-le-Sands; F. Powell, Knaresbrough (Laced); Countess Tankerville, Alnwick (Frizzled Japanese); T. Waddington, Blackburn (Black); J. Watts; H. Beldon. *c*, W. H. Robinson, Keighley (Black).

HAMBURGHS (Silver-spangled).—1 and Cup, Ashton & Booth, Mottram. 2 and 3, D. Lord, Stacksteads. *hc*, G. & S. Duckworth, Church. *c*, W. J. Thompson, Morpeth; H. Beldon, Bingley.

HAMBURGHS (Golden-spangled).—1, — Lord. 2, H. Beldon. 3, J. Brrghley, Ashtonunder-Lyne. *hc*, G. & J. Duckworth; E. Brierley, Heywood; Countess Tankerville, Alnwick.

HAMBURGHS (Silver-pencilled).—1, J. Robinson, Garstang. 2, W. M. Mann, Kendal. 3, H. Beldon. *c*, Countess Tankerville.

HAMBURGHS (Golden-pencilled).—1, D. Lord. 2, H. Beldon. 3, J. Robinson, Garstang. *hc*, J. Walker, Birstwith.

DORKINGS (Coloured, except Silver-Grey).—1 and Cup, Hons. H. & C. W. Fitzwilliam, Rotherham. 2, R. D. Holt, Windermere. 3, J. White, Warlaby. *hc*, R. D. Holt; W. Rutledge, Kendal; Miss Fairhurst, Ormskirk. *c*, — Stott, Healey. *Chickens.*—1, W. Swann, Bedlington. 2, Rev. E. Bartram, Great Berkhampstead. 3, — Stott. *hc*, R. Smalley, Lancaster; D. Gellatly, Meigle; Mrs. F. S. Arkwright, Chesterfield (2).

DORKINGS (Silver Grey, or any other variety).—1, R. D Holt. 2, J. Robinson. 3, J. J. Waller, Kendal. *hc*, W. Jackson, Bolton-le Sands; D. Parsons, Cuerden.

COCHIN-CHINA (Cinnamon and Buff).—1 and 2, W. A. Taylor, Manchester. 3, Countess Tankerville. *hc*, T. Stretch, Ormskirk; G. F. Slatter, Carlisle. *c*, J. A. Winstanley, Preston; E. Fearon, Whitehaven.

COCHIN-CHINA (Brown or Partridge-feathered).—1, T Stretch 2 and 3, W. A. Taylor. *hc*, H. Lloyd, jun., Handsworth; E. Tadman, Whitenurch (2).

COCHIN-CHINA (White).—Cup, R. Smalley, L. J. Sichel, Timperley. 3, Miss A. Williamson, Leicester. *hc*, T. Atterton, Leighton Buzzard; J. Mashiter, Ulverston.

SPANISH (Black).—1, J. Thresh, Bradford 2, H. Beldon. 3, E. Jackson, Finchfield, Wolverhampton. *hc*, J. F. Harrison, Kendal; R. Smith, jun., Malton.

BRAHMA POOTRAS (Dark).—Cup and 2, — Ansdell, St. Helens. 3, W. A. Taylor. *hc*, C. Prichard, Tettenhall, Wolverhampton; J. Watts, King's Heath; J. Sichel, Timperley; Mrs. F. S. Arkwright, Chesterfield.

BRAHMA POOTRAS (Light).—1, J. Pares, Guildford. 2, T. A. Dean, Marden, Hereford.

ANY OTHER VARIETY.—1, H. Beldon. 2, J. Sichel. 3, R. Hawkins, Durham. *hc*, T. Kew, Burton; W. A. G. James, Kirkby Lonsdale; Hons. H. & C. W. Fitzwilliam (La Flèche); W. J. Thompson, Morpeth. *c*, J. K. Fowler (Aylesbury (French).

SELLING CLASS.—1, Rev. C. H. Lucas, Stamford (White Cochins). 2 and 3, — Wakefield, Golborne, Newtoo-le-Willows (Polands and Roncus). 4, — Brierley 5, W. A. G. James (Shitans). *hc*, R. D. Holt (Dorkings); J. Gelderd. Kendal (Domesticated Wild Ducks); T. Stuart, Staveley (Hamburghs); E. Smith, Papmans, Rochdale (Dorkings); D. Gellatly, Meigle (Hamburghs); H. B. Smith, Broughton, Preston (Polands); S. Stephens, jun., Ebley, Stroud; J. Watts, King's Heath; E. Fearon, Whitehaven (2); W. W. Rutledge (Dorkings). *c*, T. J. Harrison, Kendal (Black Spanish); G. F. Whitehouse, King's Heath (Hamburghs); W. A. G. James (Shitans); Mrs. E. Bowling, Lancaster (Roncus); E. Leech, Rochdale; E. Wells, jun., Stricklandgate, Kendal (2); W. W. Ruttledge (Dorkings).

DUCKS (White Aylesbury).—Cup and 3, J. K Fowler, Aylesbury. 2, E. Leech.

DUCKS (Rouen).—1, A. Dickinson, Westcroft. 2 E. Leech. 3, J. Newton, Silsden, Leeds. *hc*, J. Banks, Kendal; Miss Waller, Kendal; H. B. Smith, Broughton, Preston; W. J. Thompson, Morpeth; J. K. Fowler, Aylesbury.

DUCKS (Black East Indian).—1, G. E. Sainsbury, Devizes. 2 and *hc*, S. Burn, Whitby. 3, F. Pittis, jun., Newport, Isle of Wight.

DUCKS (Any other variety).—1, M. Leno (Mandarin). 2, H B. Smith, Broughton, Preston. 3, — Brierley.

TURKEYS.—1, T. J. Harrison, Singleton Park, Kendal. 2, E. Leech, Rochdale. 3, N. Russell, Bryngwyn, Oswestry.

GEESE.—1, G. F. Slatter, Carlisle. 2, J. K. Fowler, Aylesbury. 3, E. Leech. *hc*, R. Rawlinson, Docker Hall, Kendal.

SPECIAL PRIZES FOR LOCAL EXHIBITORS.

GAME.—*Chickens.*—1, T. Graham, Kendal. 2, J. Barrow, jun., Kendal. 3, — Redhead, Kendal. Extra 3, H. Leighton, Beethnm. *Pullet.*—1, W. F. Redhead. 2, Capt. Arnold, Kendal. 3, Graham & Robinson, Kendal. *hc*, J. Redhead; J. Wilson, Rigmaden; J. Wells, Kendal.

HAMBURGHS.—*Chickens.*—1 and 3, W. M. MANN, Kendal. 2, J. Roberts, Burton and Holme.

SPANISH (Black).—*Chickens.*—1 and 2, — Harrison, Kendal. 3, C. R. Kay, Haverbrack, Milnthorpe.

DORKINGS.—*Chickens.*—1, R. D. Holt. 2, — Ruttledge. 3, — Waller, Kendal. *hc*, F. Wilson, Underfell, Kendal; Mrs. Hind, Kendal.

COCHINS.—*Chickens.*—1, A. Fulton, Sedgwick. 2, J. Hine. 3, — Stainton, Milnthorpe. *hc*, C. R. Kay; — James, Kirkby Lonsdale.

BRAHMAS.—1 and 2, W. L. Hind, Kendal. 3, Mrs. G. Cartmel, Kendal.

BANTAMS.—*Chickens.*—1, W. Caton, Kirkby Lonsdale. 2, Eadson, Kendal. 3, J. Busher, Kendal.

DUCKS.—1, J. Banks, Kendal. 2, J. W. Fawcett, Old Hutton, Milnthorpe. J. J. Waller.

PIGEONS.

CARRIERS.—1, T. Waddington, Blackburn 2, T. Stretch, Ormskirk. *hc*, W. Jackson, Bolton-le-Sands; — Watkins, Marden, Hereford; Messrs. Towerson, Egremont.

ANTWERPS —1, — Copeman, Birmingham. 2, H. Yardley. Birmingham. *hc*, — Cook, Lancaster; — Collinson, Halifax. *c*, R. Towers, Lancaster; — Collinson; — Beldon.

TUMBLERS.—1, W. Lumb, Rochdale. 2, Messrs. Towerson. *hc*, — Teehay, Bursengh, Ormskirk; H. Yardley.

OWLS.—1, W. Lumb. 2, Messrs. Towerson. *hc*, R. Thompson, Penrith; A. Billyrall, Nottingham; H. Yardley; T. Waddington, Blackburn; J. Watts; J. Chadwick, Park View, Bolton. *c*, — Bell, Kendal; H. Garnett, Kendal.

POUTERS OR CROPPERS.—1, T. Waddington. 2, — Beldon. *hc*, H. Yardley; Messrs. Towerson.

BARBS.—1, T. Waddington. 2, H. Yardley. *hc*, W. Jackson; J. Chadwick. *c*, T. Kew.

FANTAILS.—1, T. Waddington. 2, H. Yardley. *hc*, J. Watts.

TURBITS.—1, R. Thompson. 2, T. Waddington. *hc*, R. Thompson; T. Waddington; Messrs. Towerson

TRUMPETERS.—1, M. Waddington, Blackburn.

JACOBINS.—2, Messrs. Towerson. *hc*, T. Waddington; F. Waitt, Birmingham. *c*, Messrs. Towerson; F. Waitt.

ANY OTHER VARIETY.—1, T. Waddington. 2, T. Imrie, Ayr. *hc*, H. Garnett, Kendal; H. Yardley; — Beldon; Messrs. Towerson; W. Lumb. *c*, — Bell, Kendal; T. Waddington.

JUDGES.—Mr. E. Hewitt, Sparkbrook, Birmingham; Mr. R. Teehay, Fulwood, Preston.

NENTHEAD (CUMBERLAND) ORNITHOLOGICAL SHOW.

THIS Show was held on the 11th and 12th inst. A more chilly or uninviting region for the culture of high-class poultry it would be difficult to conceive, and yet many excellent specimens are reared and exhibited in most of the classes.

In *Game* the adult birds were superior to the young, although the second-prize pen of Black Red chickens contained one of the most perfect pullets it is possible to conceive. Of *Hamburghs* there were also some good specimens in most of the classes, notably the first-prize pens of Silver-pencilled and Spangled, although the best class in the Show proved to be that for pairs of hens. The first prize and cup for the best pen in the Show were awarded to a pair of Golden-spangled hens, the second prize to Spanish, the third to Game, and the fourth to Silver-pencilled, which were, however, a little out of condition. *Bantams* were not good, with the exception of the first-prize Black chickens, and in *Pigeons* and *Ducks* there was nothing remarkable.

Of *Cage Birds* there was a good show, most of the birds being in good trim. The cup for this section was carried off by a handsome pair of even four-pointed Norwich, the Jonque bird in this cage being perfectly marked. Those next in point of quality were the Belgians and the Green Canaries, the latter of which were of remarkable soundness of colour.

GAME.—*Black-breasted and other Reds.*—1, W. Walton, Cocklake. 2, T. Brown. *c*, T. Brown. *Chickens.*—1, J. Stepheason, Dykehead. 2, T. Brown. *hc*, W. Liverick, Nenthead; J. Stephenson (2). *c*, J. Stephenson. *Any other Variety.*—1, L. Cassor, Ulverston. 2, G. Holmes, Great Driffield. *hc*, W. Walton. *Chickens.*—1, T. Brown. 2, W. Walton.

HAMBURGHS.—*Golden-spangled.*—1, G. Holmes. 2, Rev. H. Robinson, Nenthead. *hc*, E. White, Alston. *Chickens.*—1 and 2, J. Todd, White Lee. *Golden-pencilled.*—1, G. Holmes. 2, J. Nicholaeo, jun., Carlisle. *Chickens.*—1, G. Holmes. 2, Walton & Rutherford. *Silver-spangled.*—1, G. Holmes. 2, J. Taylor. *hc*, J. G. Millican; W. Dowson; J. Nicholson, jun. *Chickens.*—1, J. J. Millican. 2, Walton & Rutherford. *c*, J. Taylor. *Silver-pencilled.*—1 and 2, J. Stephenson. *hc*, J. Brown, Sunderland. *c*, J. Taylor. *Chickens.*—1, J. Brown. 2, G. Holmes *hc*, J Nicholson. *c*, J. Stephenson.

DORKINGS.—1, D. Walton, Hudgill. 2, W. Walton. *hc*, J. Hilton; Walton and Rutherford *Chickens.*—2, W. Walton.

SPANISH.—1, H. Wilkinson, Farby. 2, G. Holmes. *Chickens.*—1, H. Wilkinson. 2, W. Bell, Alston. *hc*, W. Thompson, Nenthead. *c*, J. Story, Alston; J. Kindred.
POLANDS.—1, J. Chaplow. 2, P. Swindle. *Chickens.*—1, P. Swindle. 2, J. Chaplow.
BANTAMS.—1, G. Holmes. 2, T Hymers, Hudgill. *hc*, P. Swindle. *Chickens.*—1, G. Holmes. 2, A. Elliott. *hc*, J. D. Stephenson.
COCHIN-CHINAS.—1 and 2, J. Stephenson.
ANY OTHER VARIETY.—1, D. Walton. 2, J. Taylor. *Hens.*—1 and Cup, G. Holmes. 2, H. Wilkinson. 3, Walton & Rutherford. 4, J. Brown. 5, R. Walton. *vhc*, J. J. Millican. *hc*, J. D. Stephenson; T. Brown. *c*, T. Storey, Alston.
DUCKS.—1 and 2, J. Kindred.
PIGEONS.—*Pouters.*—1, R. & W. Walton. 2, J. Guthrie, Hexham. *Carriers.*—2, J. Guthrie. *Tumblers.*—1, J. Guthrie. 2, R. & W. Walton.

CAGE BIRDS.

CANARY.—*Belgian.*—1, T. Brown. 2 and *hc*, R. & W. Walton.
YELLOW.—1, J. Dickinson. 2, R. Walton. *hc*, J. Robson; J. Guthrie.
BUFF.—1, J. Robson. 2, T. Brown. *hc*, J. Dickinson (2); R. Walton; J. Erwin, Nenthead. *c*, R. & W. Walton; T. Brown.
YELLOW MARKED.—2, R. Walton.

WALSALL RABBIT SHOW.

THE following are the weights, ear-dimensions, and age of the prize Rabbits at this Show, which took place on December 26th, 27th, and 28th :—

	Ears. length.	Ears. wdth.	Weight.	Age.
	ins.	ins.	lbs. ozs.	mhs. dys.
1, R. Pugh, Darlaston (Sooty)	22¾	5⅜ ..	7 10 ..	8 13
2, J. Pritchard, Wednesbury (Sooty)	22	5⅜ ..	8 12 ..	7 9
ALL PROPERTIES.				
1, F. Smallman, Walsall (Black and White buck)	20½	5 ..	11 5 ..	10 12
2, D. Maybury, Darlaston (Black and White doe)	20½	5¼ ..	5 6 ..	4 0
1, R. Pugh (Yellow and White doe)	20⅜	5 ..	10 2 ..	8 13
2, R. Pugh (Yellow and White buck)	20¼	5 ..	8 2 ..	8 13
1, J. Pritchard (Grey and White doe)	21	5¼ ..	7 0 ..	4 5
2, J. Bates, Walsall (Grey and White doe)	19⅞	5 ..	6 0 ..	4 15
1, W. Hunter, Walsall (Blue and White doe)	18½	4½ ..	8 0 ..	8 10
1, J. Britchard (Tortoiseshell doe)	20½	5¼ ..	8 2 ..	7 9
2, H. F. Wild (Tortoiseshell doe)	20¼	5¼ ..	7 8 ..	9 14
1, H. F. Wild (Fawn doe)	21	5¼ ..	9 12 ..	9 14
2, J. Pritchard (Grey buck)	21	5 ..	6 3 ..	4 5
WEIGHT.				
1, F. Smallman (Black and White buck)	20½	5 ..	11 5 ..	10 12
2, R. Pugh (Yellow and White doe)	20⅜	5 ..	10 2 ..	8 13

EXTRA PRIZE.—Silver Cup for Weight; also for all Properties, K. Smallman.

JUDGES.—Mr. J. Newton, Mr. H. Hall, and Mr. H. Hatwood.

TEACHING A CANARY TO PIPE.

IT may interest some of your Canary-fanciers to hear that a Canary is capable of learning to pipe like a Bullfinch. I had a pair of Canaries from Malta, given to me by a soldier's wife four or five years ago, and by frequently playing a little German air ("Trab Trab") this was caught up and sung so perfectly, that persons in the garden could not always distinguish the song of the bird from the organ. He lost his mate last summer, and though there was another pair in the same cage (a large one), he moped and was silent for several months. I gave him another mate and the whole cage to himself a month ago; he very shortly recovered his spirits and his song. I have more than a dozen birds of various kinds in a different compartment, which when singing all together one would suppose would be rather confusing, but I distinguish his sweet pipe in the midst of them. By reminding him occasionally of the air, and giving him a few hempseeds for proficiency, he remembers it perfectly, and generally greets me with it the first thing in the morning, or if I go to him and invite him. On second thoughts, my first bird died after learning the song and helping to educate his firstborn.—SOUTH WALES.

[The above communication is most interesting, but it ought not to surprise; for if a Canary can be taught one description of song which in its endless variety defies any but a carefully educated ear to detect its constituent parts, why should it not learn another in the shape of a simple air? But more marvellous still, I know of two instances, each authenticated beyond a doubt, in which Canaries have been taught to speak. —W. A. BLAKSTON.]

"B. & W.'s" APIARY IN 1871.

I BEGAN operations among my bees on the 22nd of May, by driving my pure Italian stock B. The swarm was put in the same place in a hive with some comb in it. Unaccountably this hive swarmed naturally on the 4th of July, a tiny swarm, before the bees had half-filled their box with comb. This was hived in a small box and put on my garden stand in place of H (see page 407 of last volume). It remains there still, supported entirely upon sugar. My notion is, that B, when driven on the 22nd of May, had an old Italian queen (imported), who must have died some time in June, for I observed a royal cell in it. Further, I am of opinion that one of the youthful princesses must have led off the July swarm. However this may have been, both are alive, but the bees in the swarmed stock B are the strongest; both, too, have well-marked Italians throughout. The original parent hive, out of which I drove the first swarm on the 22nd, after taking out a piece of brood-comb, I put in the place of D, a very strong degenerate hybrid stock, which I shifted into the fowl-house to the vacant place N. Out of the piece of brood-comb (pure Italian of course), I made up a swarm to put in place of C, which I also shifted on the 23rd of May to the fowl-house, where it now stands in place of L, previously sold.

It was the shifted stock N whose queen, as I believe, migrated the same or the following day back to her old stance in the bee-house (D), and led off a swarm therefrom on the 24th of May, about which some controversy arose in the summer between myself and your esteemed correspondent, Mr. Lowe. This gentleman positively denied—too positively as I ventured to think—that queens ever take airings in this sort of way. The occurrence which I recorded was differently, and, no doubt, reasonably accounted for; but it still remains an open question. At page 499 of last volume will be found a corroboration of my own view, in an extract from the American "Bee-keeper's Journal."

This swarm with its degenerate hybrid queen and bees I placed in an empty hive on the vacant stance A, in the bee-house. There it remained degenerate as ever; whereas, the artificial stock D, out of which it swarmed, abounds in beautifully-marked Italians, and has, I doubt not, a young queen raised out of the brood-comb, which I gave them only two days before the degenerates quitted it.

June 7th.—A second awarm issued from N, which was hived and placed on the garden stand the same day, and is numbered H2. These are still alive and well.

June 8th.—A second swarm issued from D, located on garden stand, but being overlooked died of starvation in November.

June 30th.—A fine natural swarm issued from F, which has an imported Italian queen, the last Mr. Woodbury procured for me. It is still doing well as J2, on my garden stand.

July 8th.—A fine swarm out of a nameless stock with a pure-bred Italian queen hived as I, in the same place.

July 10th.—A second swarm out of F, put on garden stand and labelled J, by dint of feeding is still alive.

July 13th.—The last swarm of the year came off to-day, a maiden swarm, out of A, in bee-house. I gave them a super with some 8 lbs. of honey to begin with. They are still alive and well. This hive, I2, makes the sixth on my garden stand.

It will be seen that my apiary at the close of the year numbered fifteen stocks, which stand as follows :—

BEE-HOUSE.

A. Degenerate hybrids. Queen b. July, 1871.	B. Pure-bred Italian. Queen b. June, 1871.	C. Same as B.
D. Same as B.	E. Hybrid Italian. Queen b. 1870.	F. Same as B. Queen b. July, 1871.
	G. Nil.	

GARDEN STAND.

H. Pure-bred Italian. Queen imported, 1868, or pure-bred, 1871, June.	I. Pure-bred Italian. Queen b., 1868.	J. Pure-bred Italian. Queen b. July, 1871.
H2. Hybrid queen degenerate, b. June, 1871.	I2. Degenerate hybrid. Queen b. 1870.	J2. Imported queen, 1870.

FOWL-HOUSE.

K. Nil.	L. Hybrid Italian.	Queen b. 1870.
M. Pure-bred Italian. Queen b. 1870.	N. Degenerate.	Queen b. June, 1871.

Besides those mentioned above, I had other swarms which I gave away or returned to their hives. The year with me has been prolific in swarms beyond all my experience. Of honey there has been none to speak of. I obtained a fine super from M, containing about 25 lbs. nett, also about 8 lbs. from C, 7 lbs. from D, and 4 lbs. from E, total 44 lbs. of honey, which is the smallest honey harvest that has been gathered-in by me since

1861. Only one of my fifteen stocks is wealthy enough to survive the winter and spring without feeding. Of the rest I fear half will die, not from want of attention, but from the severity of the weather, which has made me cease feeding altogether earlier than I should have done.—B. & W.

OUR LETTER BOX.

Bristol Show.—Mrs. F. S. Arkwright, Sutton Scarsdale, Chesterfield, writes to us that our reporter was quite wrong in stating that her first-prize Dorking cockerel was an old bird. She states, and we are sure truly, that it was hatched in March last. It was claimed at Bristol at the catalogue price, ten guineas.

Sunderland Poultry Show (*C.*).—Not being advertised we conclude it was a small local show.

Plymouth Show (*J. Long*).—We made no inferences, nor can any be drawn fairly from what we said. We do not know anything about your connection with a contemporary.

Paisley Ornithological Association's Show.—The reporter has omitted to state, that for the best Gold-pencilled Hamburgh cock, the special prize was awarded to Robert Macnab, Cardonald by Govan.

Poultry (*G. Dyson*).—No such periodical. "The Poultry Book" is published at our office, and can be had free by post for 6½*d.* postage stamps.

Egg-eating Hens (*A Subscriber*).—There are only two modes of prevention—watching the laying hen and taking the egg, or having the trap nest depicted on p. 330 of our last volume.

Exchanges (*H. Welsh*).—We insert brief notices of exchanges desired for one shilling each.

Brahma Pullet Dead (*E.*).—There was a stoppage. You did right in administering the castor-oil, but in our opinion the gin was injurious. You may accept it as an axiom that wine or gin should only be administered in extreme cases, when nothing can increase the danger, and then they should be given by means of bread soaked in them. Our impression is, that on careful examination you will find an egg in the passage so fixed that it impeded the exercise of all natural functions. Had that been assisted by means of a feather dipped in oil, the bird would probably have been alive and awfully emptied in increasing the food of man in the shape of eggs.

Cochin Chinas not Laying (*E. C. P.*—It may be you have been deceived in the age of your fowls without its having been done wilfully. We do not believe a Cochin can go to ten months without laying, and it is only the exception when they lay at five. Laying in the winter is a question of age, not of breed. There is no breed whose province it is to lay out of season. Laying in the winter in these latitudes (and in others that are called more favoured) is entirely a question of months and not race—and only pullets lay in the winter. You are to have a little patience, breed some chickens this year, and you will see you will have eggs from pullets before they are ten months old. We have no fault to find with your feeding, except that we would abjure the cat's meat. Instead of a pole for going in and out of the house, give them a hole in the door, supply them two or three times per week with heavy sods of growing grass. Let them have road grit to back and dust in; and if they do not eat their eggs, they will soon do away with your grievance. What is the floor of their roosting house?

Black Bantam Points (*Inquirer*).—You are altogether wrong. The only Bantam that must have the drooping wing is the Sebright. It is part of the breed that they should have it, but in no other bird is it required. We have not to take up cudgels for judges, and we know in the present day, when their name is legion, there are curious and inexplicable awards, but we are not aware there has been any change of opinion among the admitted judges. Black and White Bantams were shown before the Game were manufactured. It was always a positive point that in both breeds the birds should be smart, clean, earlobe small, and that the cocks should have very long sickles. These do not match with drooping wings. The carriage of a Sebright, with the tail of a Black or White, would cause the latter to be thrown over his back, and the bird would be disqualified as squirrel-tailed. Black Bantams should be small; they should be neat and close in feather; quite black, save that they may have gloss on their feathers; taper legs not too stout, faultless small white deaf ears, smart carriage, and the cock should have long streaming feathers, carrying his tail rather low.

Turkey Poupy (*A Young Beginner*).—Give your Turkey some bread soaked in strong beer. Give her onion tops in her food, and administer every nigh. till she begins to mend two pills of camphor, each the size of a garden pea). Your Brahmas cannot take the roup from her. They are not subject to it. Their complaint is, "wasting." They rarely have it, and it is not infectious. If they are failing, give them bread steeped in strong beer. Meat and other stimulating food will make birds lay; but it is a lamentable process, the number of eggs is lessened rather than increased, and the bird is often acurably injured.

Game Bantam Points (*Spes*).—The points of a Game Bantam should be identical with those of a Game cock. The only difference between the two that is permitted is that of size. Sharp, clear, snake-like head, scanty hackle and saddle, drooping tail rather than carried upright, hard plumage, wing clipped up to the body, well placed spur, absence of duck foot, moderate thigh. All these points are required in a Game Bantam. A Game fowl with a double comb should be as rare as a man with two heads.

Black Polands' Crests—Minorcas (*H. Bovvr*).—The only way in which you can keep the top-knots of your Polands clean, is to fasten them up with an elastic band. They not only get wet when they are unconfined, but they become heavy and fall around their eyes whenever the fowls eat or drink. The confinement you speak of will do very well for a temporary residence, for instance during bad weather, but not for a continuance. What is the flooring of it? The Minorcas are extinct; they were supposed to be red-faced Spanish, and were common in Devonshire. A White Dorking cock and hen weighing 16 lbs. would be large birds of the breed.

Pigeons' Nest Pans (*New Subscriber*).—We do not know where the earthenware pans you mention are to be had. We do not think they are made now.

Throat Rattle (*Light Brahma*).—A table-spoonful of castor-oil given to the hen two nights in succession, followed by feeding for a day or two on bread and ale, with a pill of camphor night and morning.

Aviary for Pigeons (*Yorkshire*).—There would seem to be no reason why you should not make the roof of glass, as we presume your birds are only to be in the place by day, and not to breed in it. If the latter it would be too hot in summer. You will, of course, have open wirework at the side, for they want air as well as light and sunshine. The usual plan is to have the roof of corrugated iron, with a window in it, and the side wire, either end being close, but much depends on the position of yours, and the use you put it to. A very shallow vase in the centre, or one nearly filled with gravel, and then water on the top would be nice as a bath, and ornamental likewise.

Gold Fish in an Aquarium (*Hebe*).—Whether in an aquarium or in a glass globe they require feeding; the following, published in an American paper, coincides with our own experience. "I have kept gold fish for two years or more. The first six months, or thereabouts, I lost eight fish by following the instructions of parties from whom I purchased. I then thought I would use my own judgment in the matter and see if feeding would kill them, as I had been informed by the aforesaid dealer. I now have five gold fish, three minnows, one crawfish or crab, and four turtles in an aquarium 30 by 16 inches and 12 inches deep. I have on the bottom about 2 inches of fine lake sand, and scattered here and there stones built up or piled so as to form run-ways. I feed them about twice a week with fresh beef, cut into small pieces and dropped on the water, when, quick as a trout after a fly, they will seize the pieces until satisfied. I have often seen them jump 3 inches above the water trying to catch a fly on the side of the glass. I keep a small plant of Calla in a pot standing in the water all the time; some say it helps to keep the water pure. I change and renew the water twice a-week during them winter and three times during the summer."

Dying Grasses (*A. S.*).—We cannot give details of the processes for various colours. The readiest way would be to use the dying fluids advertised. We forget the proprietor's name, but any chemist could tell you.

REMARKS.

10th.—Very dense fog all day.

11th.—Very wet in the morning, rather better in the afternoon, and clear in the evening.

12th.—Fine morning and early afternoon, dull later, and rain at 10.30 P.M.

13th.—Dark and rainy in the morning, and partially so all day.

14th.—Particularly bright in the morning, slight shower about noon, fine in the afternoon and evening.

15th.—Fine with white frost till 8.30 A.M., then foggy till 10.30 A.M., when the sun got through the fog for a short time, but thick again in the evening, and the same at Kennington, though bright in some parts of London, and at Chelsea and Pimlico.

16th.—Dull morning, occasionally bright during the day, but cold throughout.

Another damp, thick, muggy week; dense fogs on 10th and 15th; sharp frost on 15th.—G. J. Symons.

COVENT GARDEN MARKET.—January 17.

Superior qualities of goods are now in better inquiry; Asparagus, Sea kale, Dwarf Kidney Beans, and Cucumbers taking the lead in the demand. Rough produce is heavily supplied, and large quantities are disposed of at very low rates. Cornish Brocoli is coming in good, selling at from 2*s.* to 4*s.* per doz. by the crate. Imports of foreign produce are much lighter.

From observations taken near London during forty-three years, the average day temperature of the week is 44.9°; and its night temperature 31.6°. The greatest heat was 57°, on the 29th, 1863; and the lowest cold 8°, on the 30th, 1857. The greatest fall of rain was 0.70 inch.

CULTURE OF THE HYACINTH AND LILY OF THE VALLEY.

THE early part of the year being the time when a general collection of Hyacinths requires attention, a few remarks on the culture of this, the grandest of all spring flowers, will not be out of place. The mistake is sometimes made of leaving the pots out too long in the plunging material, and sometimes of not plunging them in a proper position. I have seen Hyacinths potted at the usual time (about the end of October), and the pots placed under the stage of the greenhouse, and carelessly covered over with leaf mould, ashes, or any similar material that was at hand. Now I do not think a more unsuitable spot could be selected for them, as some of the pots may be deluged with water, others may not receive a drop, whilst in many respects the place certainly is not one that should be chosen for such a purpose. The best position for them after they are potted is an exposed one out of doors, on a hard, wormproof bottom, the pots being covered to the depth of 6 inches with cocoa-nut fibre refuse, spent tan, or leaf mould, but not ashes. They should be removed to some glass structure by the second week in January, though some, in order to retard them, allow them to remain until the end of February. The spikes are thus sometimes injured by being allowed to grow so long in that condition, and then the seedsman who supplied the bulbs is blamed. Like "Stiff Soil," in the number for December 21st, in reference to his Gladiolus roots, "I blamed the bulbs, the vendor blamed the soil." So with our seeds. When they do not vegetate freely we say, "That must have been bad seed Mr. —— supplied me with this year;" when probably the birds, which have a keen eye for such things, observed the young seedlings before we did, and picked them out as they came through the ground.

The best position for Hyacinth pots when removed from the plunging material is close to the glass of a low span-roofed pit, heated with hot-water pipes, so that the temperature cannot fall below the freezing-point. Should it not be convenient to remove them to such a structure, they will do in a cold frame; but the pots must be plunged, and double mats must be thrown over them if severe frost set in. A small pot should be inverted over the crown of the bulb, should remain for a week, and then be gradually removed, so that the incipent spike may receive no check to its growth. After this, air must be abundantly admitted to prevent the spikes from becoming in any way drawn. If the bulbs throw up two or three spikes these must be removed, allowing only the strongest to remain—that is, if they are required for exhibition; but if required for home decoration, all the spikes that are formed may be allowed to remain. Where a continued display is required, successive batches will require to be told off to the forcing pits. The temperature should be kept rather low at first, but gradually increased until a regular night temperature of 65° is reached.

Sometimes there is no forcing pit convenient; indeed, I generally place all such subjects on shelves near the glass in Pine or Cucumber houses; but where it is necessary to remove plants from a cold pit into a temperature of 60° or 65°, it is better first to place them in a hotbed where they can have a little bottom heat to cause the formation of a larger quantity of roots in proportion to the top, and thus prevent failure. When the first flower or two on a truss has fully expanded, the pots should be removed to the greenhouse and conservatory, which ought to have a rather higher temperature when plants are being removed to them from the forcing houses.

Lily of the Valley is one of the sweetest little gems of the early spring months, and well adapted for early forcing. The roots, if intended to be forced in large quantities, ought to be brought in during the early part of November, and potted at once, as early potting insures a larger formation of roots, and fits the plants better for early forcing. When required for very early forcing, a house or pit, with a little bottom heat and an atmospheric temperature of 45° at night, is best. Where this cannot be obtained, the pots should be placed in a dung frame with a gentle bottom heat, or a bed formed entirely of leaves. This is necessary to bring the roots into action before unduly exciting the crowns, and if this is not done the flower-trusses are thrown up without leaves, and the plant thus robbed of its beauty. To be sure of obtaining leaves, I force the old plants which flowered in pots the previous season to throw up plenty of leaves, but few flowers.

Success in forcing all classes of spring flowers is attained by exciting vigorous root-action before the plants are placed in a high temperature; and just in proportion as this is observed so great will be the measure of the success. Judicious watering is likewise an important consideration.—J. Douglas.

BROMELIACEOUS PLANTS.—No. 1.

It is a source of great pleasure to me, an enthusiastic admirer of the order Bromeliaceæ, to find the public again taking an interest in this far-too-much-neglected family of plants. In my earlier gardening days these plants were highly prized, and I have little doubt but that I shall soon see them again receiving the care and attention to which their great beauty deservedly entitles them. I am led to this hopeful state of mind by seeing them more frequently in amateurs' houses, and from the frequent recent introductions of new species, in which the past year has been exceptionally prolific. I think, also, that the Royal Horticultural Society should take them under their special care and offer prizes for them, for, although I am quite aware that such a proceeding would not enhance their beauties, it would undoubtedly increase and improve their cultivation. This would be productive of a greater number of amateur admirers, and a demand having been created, plant-collectors would find it worth their while to send us home many new kinds which have hitherto been neglected for more profitable plants. In order, therefore,

to draw the attention of some of the readers of the Journal who have hitherto neglected the Bromeliads, to their many claims to notice, I purpose giving a few plain and practical descriptions of some of the most beautiful kinds now to be found in our gardens, commencing with *Vriesia brachystachys*.

This very elegant species has been chosen for the first plate of the new series of the "Floral Magazine," and a very beautiful object it is when five or six scapes are seen together. My attention was first called to this plant about three years ago when visiting some of the principal German gardens, and although it was not in first-rate condition at that time, I saw sufficient of it to induce me to suppose that it would develope greater beauties under a more liberal course of treatment, and I accordingly procured it. I have now no hesitation in saying it deserves to be grown in every collection, however small.

The plant I have introduced to my readers' notice is dwarf and compact in habit; the leaves are light green, sheathing at the base, and arranged in a rosulate manner, so as to give it a vase-like appearance. The flower-spike is erect, produced from the centre of the plant, and bears upon its summit a distichous scape of narrow boat-shaped bracts, the upper half of which are dark green with a crimson base. The orange-yellow flowers vary from six to twelve in number, are all longer than the bracts, crimson at the base, and tipped with black at the apex. So persistent are these flowers and bracts, that the plant when in bloom retains its peculiar and striking contrast of colours for many weeks, and may be placed without injury in a vase for the decoration of the drawing-room or a lady's boudoir. I think none can gainsay my assertion that it deserves the attention of every plant-grower.

The cultivation of Vriesia brachystachys, like that of the majority of the order, is extremely simple. They naturally lead an epiphytal life, and this fact must be borne in mind by amateurs when placing them, for their own personal convenience, in flower-pots. In such a state good and thorough drainage is not only essential to their well-being, but actually to their very existence, and I invariably find when any of them in pots get into bad order, that placing them on a block of wood, and then suspending them in a moist warm atmosphere, is sure to restore them to their wonted vigour. The soil for this plant should consist of two parts good leaf mould, two parts peat, and one part each of light loam and sand. Before leaving this subject, however, I must just revert to a practice too much in vogue with gardeners, and that is turning the plants upside down to empty the water from the natural receptacles formed by the overlapping of the base of the leaves. Nothing in my estimation can be more prejudicial to the health of this plant than such a practice, for I find that water standing in these is the actual life of the plant, and therefore I invariably make the crown of the plant the receptacle for all the water given. That portion which runs over and trickles down the plant is usually sufficient for the roots.—EXPERTO CREDE.

THE ACTION OF NITROGEN GAS ON PLANTS.

By CUTHBERT W. JOHNSON, F.R.S.

THE action of the nitrogen of our atmosphere upon vegetation has long been a moot question with chemists. That this gas should form 79 per cent. of the air we breathe, that it should be a constituent of so large a proportion of vegetable substances, and yet that those vegetables should not derive any portion of it from the atmosphere, has ever been regarded as doubtful. It is true that the most careful chemical researches have hardly detected any absorption of nitrogen gas by plants. The different very valuable researches on this important inquiry were some time since described by Professor Way (*Jour. Roy. Ag. Soc.*, vol. xvi., p. 249). If, however, the absorption of the nitrogen gas of the atmosphere is still a moot point, there is yet no doubt of the value to vegetation of the nitrogen contained in the nitric acid, and the ammonia which is contained in rain water, and which Way calculates to be annually equal per acre to the manuring power of 1 cwt. of guano. The agriculturist, adds the professor, "may profit by this newly discovered bounty of Nature if he will take full advantage of the atmospheric manure by means of drainage, which promotes the equal flow of water through, instead of over, his soil, by deep cultivation and thorough pulverisation of the land, which brings every part of it into contact with the air. The atmosphere to the farmer is like the sea to the fisherman; he who spreads his nets the widest will catch the most."—(*Ibid.*, p. 266.)

But then there are certain phenomena which induce the suspicion that in some way, either direct or indirect, the atmospheric nitrogen gas is made subservient to the growth of plants. Thus nitric acid, which is composed of nitrogen and oxygen, is found in rain water, and also ammonia (composed of nitrogen and hydrogen), is as generally present. As, then, the combination of nitrogen with oxygen forms nitric acid, and, when united with hydrogen, ammonia, both very valuable fertilisers, the inquiry naturally suggests itself as to whether these gases might be profitably combined by artificial means. An eminent civil engineer, Mr. James Nasmyth, has lately suggested that this might be accomplished by percussive compression (*Jour. Roy. Ag. Soc.*, vol. vii., p. 436). He observes in his paper, which is introduced by some remarks by Mr. James Caird, and has appended to it an outline of a suggested gas-compressing machine, that "Nitrogen, although a most abundant constituent element in our atmosphere, does not appear to act so readily as a fertiliser as when it is presented to the roots of plants in combination with some other substance, from which combination plants abstract the nitrogen in a manner most effectually conducive to their fertility.

"All animal substances, especially when such are in a state of decomposition, are well known to be very effective as manures. This arises from the fact that in that condition they contain ammonia, which, being composed of hydrogen and nitrogen, the roots of the plants decompose the ammonia and appropriate the nitrogen greedily, as their most favourite food, and hence its efficacy as a fertiliser.

"Reasoning on this subject full forty years ago, and considering the inexhaustibleness of the store of nitrogen we possess in our atmosphere, it occurred to me that, could we but devise some means of laying hold of this nitrogen of the atmosphere, and fixing it in combination with some other element, so as to enable us to present the result directly to the roots of plants, we should, in that way, supply them with their most effective food as manure, derived from an inexhaustible source around us, instead of having to obtain the desired nitrogen, as we do at present, by going all the way to Peru for it in the form of guano, which owes its efficacy as a fertiliser chiefly to the presence of ammonia, from which the plants, by means of their roots, abstract their favourite nitrogen. Reasoning on this subject, as I have said, it occurred to me that if by some mechanico-chemical process we could manage to knock the nitrogen and oxygen of the atmosphere into chemical combination, and at the same moment combine the so-produced nitric acid with some mineral substance which would permanently fix the combination in a portable form, we should thereby get hold of a source of fertilising power as inexhaustible as it would be effective. In following out this train of reasoning, I called to mind the fact that traces of nitric acid are found in the rain that falls during thunderstorms; and the observed increase of fertility which follows such thunderstorm rain is due, it is supposed, to the nitrogen carried to the roots of plants by the minute admixture of nitric acid in the rain which falls on such occasions.

"Also let us bear in mind the wonderful efficacy of a blow, or percussive action, in bringing about a true chemical combination between certain elements which otherwise might lie for ever in close juxtaposition without ever entering into chemical union. The efficacy of percussive force in this respect is well known in the case of all fulminating compounds. Viewing the thunderstorm effect above referred to as a percussive compressional agency, it occurred to me that we might attain the grand object of chemically combining the nitrogen and oxygen of the atmosphere, for the service of agriculture, by subjecting atmospheric air to exceedingly violent percussive compression in the presence of some cheap mineral substance which had a strong affinity for the nascent nitric acid, which I imagine would be the immediate result of such violent percussive compression. Dry slacked lime would appear to be the most suitable substance for effecting this object: the result would be nitrate of lime. Should we thus be so fortunate as to knock into combination the constituent elements of the atmosphere, and so produce a fertilising agent of the most potent efficacy from an inexhaustible source at home, instead of, as at present, going for it, in the form of guano, all the way to Peru, a great result might ensue."

BROCCOLI.—The Cornish Broccoli trade of 1872 has commenced in earnest. During the first fortnight of this month upwards of 25 tons have been sent away by rail, principally to

London. Price from 1*s.* 6*d.* to 2*s.* per dozen heads. £60 have been given this season for one early acre.—(*Times.*)

HISTORY OF THE GLASTONBURY AND BENEDICTINE PEARS.

I WISH to make a few more remarks on the Glastonbury Pear which may help to settle two points. Firstly, Its identity with the Esperine appears to be very doubtful; and secondly, Mr. Sampson's Benedictine and the Glastonbury Pear are the same. From your editorial remarks I learn the Esperine could not well have been distributed in this country before 1850, or, in other words, it was not known to be cultivated in England thirty years ago. There can be no doubt the Glastonbury Pear tree is older, and for twenty years has been grown against a garden wall by a resident in the town, who has known the original tree thirty years. When I sent you the fruit in 1865, I ought to have stated the Pear tree was growing at Glastonbury, and not, as you supposed, at Edgarley from whence I wrote. My first impression was the tree had never been grafted, but now I think otherwise.

The original Pear tree now promises to bear a heavy crop of fruit; should it do so I will forward some to your office for comparison with those grown in a garden, also some of the leaves. The tree stands in a hedge dividing two Apple orchards; near it are two Elms more than forty years old, and in the same hedge are several Pear trees, never grafted, and the fruit worthless. I consider they were stocks planted about the same time as the Apple trees, and were intended to be grafted, but only one was done, the Glastonbury Pear. The Apple trees in both orchards are about the same age, certainly not less than forty years.

When fruit are sent for identification it should be stated whether grown on a standard or against a wall, and the aspect, as exposure to a warm sun greatly adds to the colour of the fruit. The fruit I sent to Mr. Rivers were grown against a wall and highly coloured, much more so than those sent to you in 1865, which were grown on a pyramid. I make the above remark, as you notice a difference between the Benedictine, which you say resembles the Brown Beurré, and the Glastonbury Pear; they may not have been grown under the same conditions.

Previous to my sending the Pears to Mr. Rivers, some were sent to Mr. Cramb, who named them Brown Beurré, and his opinion was also confirmed by some one who saw the fruit. Mr. Lovell, in 1862, obtained grafts either from the tree in the orchard hedge, or from Mr. Chapman, who was the first to bring the Pear into notice, and had then grown it against a wall for many years. In 1865, as already stated, I sent you two Pears which were grown in Mr. Lovell's garden, and as your report was then so favourable (and which I have sent to Mr. Rivers with the Pears), I largely grafted the variety in 1866 and 1867, as I wished the Pear to be distributed, and mentioned it to two nurserymen. About that time, or a little later, Mr. Lovell sent to Edgarley for some of the grafts, which he had promised to Mr. Sampson. I was pleased to give them, as I considered there was a fair chance of the Glastonbury Pear being distributed. Last February Mr. Lovell called my attention to an article in the *Gardeners' Magazine*, page 84, and wished me to answer it, as it was very likely to mislead the public. No doubt that artiele if not noticed helps to establish a new Pear, and to confuse the identity of the Benedictine and Glastonbury Pear. The followiug is the article:—

"Among new fruit now in course of being distributed, there is another west-of-England Pear named the Benedietine. This is in course of distribution by Mr. Thomas Sampson, Preston Road Nurseries, Yeovil. This variety was raised from a cross between Huyshe's Princess of Wales and Van Mons Léon Leclerc, by Mr. W. Lovell, of Glastonbury. The fruit when ripe has a handsome appearance, and is nicely tinted with red on the side towards the sun; the flesh is melting, rich, and juiey, the flavour said to be very fine, and with an exquisite aroma. It is a midwinter Pear, in use from November to the end of January. It takes its name from this, that the garden of Mr. Lovell in which it was fruited adjoins that of the Benedictine Monks at Glastonbury. Mr. Lovell has placed the entire stock in the hands of Mr. Sampson for distribution."

Many grafts and trees I have given away in this neighbourhood, and should any of your readers wish for grafts I shall have much pleasuro in sending some. There is no reason why the Pear should be called Benedietine, and until the Pear is identified I would suggest that it be called the Glastonbury Pear, a title which at present it has a right to, and is known by in the neighbourhood. The Pear is ripe towards the end of October, and may sometimes last until the end of November.—JOHN ALBERT PORCH, *Edgarley, Glastonbury.*

It is always agreeable to see a controversy conducted with good nature: under such feelings I venture to inquire into the origin of the Benedictine Pear. I do not know Mr. Lovell. Mr. Sampson I know as an honourable nurseryman who would not knowingly deceive the world. According to what is known of the origin of this Pear it was raised from a cross between Huyshe's Prince of Wales and Van Mons Léon Leclerc, both fine Pears. The former was sent out in 1860, or about that time, as maiden trees on the Pear stock. Such trees would not bear fruit till 1864 or 1865; the young seedlings would, say, be in a growing state in 1865 or 1866, and, from my long experience, they would not bear fruit till eight years old, or rather ten years old, as it is very rare for a seedling Pear in this country to bear under that period. Now, according to the lowest calculation, taking eight years, the trees would not bear till 1872. The Benedictine Pear has been under cultivation two or three years—I received my trees in the autumn of 1870—this seems to me to reduce the bearing state of the seedlings to an incredibly short period. I write this merely as an inquirer, having taken your statement (page 58) as a fact. There has been, probably, some mistake as to its origin which may be at once explained.—THOS. RIVERS.

[Mr. Porch has been kind enough to send us two large pieces, apparently two large pyramids, of the Edgarley Foundling or Glastonbury Pear, by which we are somewhat confirmed in our suspicion that the Edgarley and the Benedictine Pears are distinct sorts, and that by some means two varieties have got together under the same name. In our notes on Benedictine we remarked that it "very much resembles Brown Beurré in form and colour;" and it is remarkable that, according to Mr. Porch, that careful observer Mr. Cramb should have come to the same independent conclusion. That the doubts we expressed as to the Pear sent to us in 1865 by Mr. Porch, and which we named Edgarley Foundling, is the same as that sent to us last year by Mr. Sampson under the name of Benedictine, are well founded has some confirmation from the two specimens of the tree now sent us. One is much stronger and more robust than the other; the colour of the shoots is a bright, clear, yet deep reddish brown or mahogany colour, thickly strewed with large distinct clear freckles (*lenticelles* as Mr. Rivers calls them), and the buds prominent. The other is not so thick or robust in growth, the shoots of a greyish olive colour, freckles small and sparse, and not much lighter than the colour of the wood. We draw no other conclusion from these facts than that they confirm our suspicion, and that probably the mahogany-wooded variety is Brown Beurré. We leave others to investigate the matter farther.—EDS.]

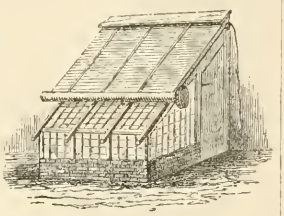
COLD PRODUCED BY RADIATION AND EVAPORATION.

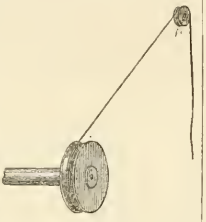
LETTERS have been received by us so frequently of late complaining that the heating apparatus employed was not quite sufficient to maintain the required temperatures, that we feel convinced an attention to the means of checking radiation and evaporation from the glass of the stove, greenhouse, conservatory, and pit would be an effective resource. Glass radiates heat very rapidly, and during a cloudless night it quickly, and to a very low degree, cools the air in contact with it. Dew is deposited upon the glass, and then heat has to be supplied for the evaporation of that. Clouds reduce the radiation from the glass of our garden structures, and much more effectively do coverings outside but near the glass. For example, a thermometer placed upon a grass plat, exposed to a clear sky, fell to 35°; but another thermometer, within a few yards of the preceding, but with the radiation of the rays of heat from the grass checked by no other covering than a cambric pocket-handkerchief, declined no lower than 42°. No difference of result occurs whether the radiating surface be parallel or perpendicular to the horizon; for when the mercury in a thermometer, hung against an openly exposed wall, fell to 38°, another thermometer against the same wall, but beneath a web of gauze stretched tightly at a few inches' distance, indicated a temperature of 43°.

For this reason, sustained as it is by the experience of gar-

deners, we recommend the more general adoption of outside blinds. They are useful for shading in summer as well as for retaining heat in winter, and at this season they may be used even during the day on the roofs of many of our glazed structures without injury to their tenants. The following is an arrangement we would recommend.

The blind is fixed at the top of the roof, the roller passing up and down when required, as shown in the accompanying drawings. A thick string passes from the hand round a pulley fixed at the corner of the roof, and continues onward to the wheel attached to one end of the pole. Supposing the wheel to be at the bottom—that is, let down, the string will then be turned many times round the large wheel, say 6 inches in diameter. The action is thus:—You pull the string passing over the pulley, which unwinds the string turned many times round the wheel, and as the string is gathered into the hand the pole turns round, winds up the blind, and proceeds with its burden until safely landed under its wooden covering at the top. There is some little accommodation required to learn how best to get the far end of the pole to reach its destination at the same time as the near end; but this, like all such matters, simply requires a slight observation to make the arrangement simple and effectual. The covering or locker for the blind, when drawn up, works on hinges and shuts down, resting on the roof, thus securing the blind from rain or damp.





The bearers should be four in number, about 3 inches from the roof, half an inch thick, to preserve the heat generated within, and to exclude more effectually the outer cold. The bearers to project beyond the glass at the lower ends. Let the blind down 1 foot beyond the glass, which serves the purpose of a blind for the front in keeping out the frost.

The blind is of a brown coarse stout canvas, such as is used for packing, 2 yards wide, at 9*d.* per yard. Before fixing up stretch it on the ground, and brush well over twice with boiled linseed oil.

As a proof of the cooling powers of radiation, and as a hint sometimes useful when the ice-house fails, we copy the following from our contemporary *Nature*.

ICE-MAKING IN THE TROPICS.

The most marked example of the influence of radiation of heat on temperature is its influence on the production of artificial ice by the natives of India.

The fields in which the ice is made are low, flat, and open; and the ice is produced in large quantities when the temperature of the air is 16° or 20° F. above the freezing point; and the plan followed is an interesting example of accurate observation applied to practical purposes by a people now ignorant of science. The same process has been employed from time immemorial in India with scientific accuracy; and while the theory was explained by Dr. Wells (Essay on Dew, 1814), the practical application was not so well understood; and this first led me to investigate the subject in India (Experimental Essay; Jour. Asiatic Society, Calcutta, vol. ii., p. 80.)

The following method is employed by the natives of Bengal for making ice at the town of Hooghly, near Calcutta, in fields freely exposed to the sky, and formed of a black loam soil upon a substratum of sand.

The natives commence their preparations by marking out a rectangular piece of ground 120 feet long by 20 broad, in an easterly and westerly direction, from which the soil is removed to a depth of 2 feet. This excavation is smoothed, and is allowed to remain exposed to the sun to dry, when rice straw in small sheaves is laid in an oblique direction in the hollow, with loose straw upon the top, to the depth of 1½ foot, leaving its surface half a foot below that of the ground. Numerous beds of this kind are formed, with narrow pathways between them, in which large earthen water-jars are sunk in the ground for the convenience of having water near, to fill the shallow unglazed earthen vessels in which it is to be frozen. These dishes are 9 inches in diameter at the top, diminishing to $4\frac{3}{10}$ inches at the bottom, $1\frac{3}{4}$ deep, and $\frac{3}{10}$ of an inch in thickness; and are so porous as to become moist throughout when water is put into them.

During the day the loose straw in the beds above the sheaves is occasionally turned up, so that the whole may be kept dry, and the water-jars between the beds are filled with soft pure water from the neighbouring pools. Towards evening the shallow earthen dishes are arranged in rows upon the straw, and by means of small earthen pots, tied to the extremities of long bamboo rods, each is filled about a third with water. The quantity, however, varies according to the expectation of ice—which is known by the clearness of the sky, and the steadiness with which the wind blows from the N.N.W. When favourable, about 8 ozs. of water is put into each dish, and when less is expected, from 2 to 4 ozs. is the usual quantity; but in all cases more water is put into the dishes nearest the western end of the beds, as the sun first falls on that part, and the ice is thus more easily removed, from its solution being quicker.

There are about 4590 plates in each of the beds last made, and if we allow 5 ozs. for each dish, which presents a surface of about 4 inches square, there will be an aggregate of 239 gallons, and a surface of 1530 square feet of water in each bed.

In the cold season, when the temperature of the air at the ice fields is under 50° F., and there are gentle airs from the northern and western direction, ice forms in the course of the night in each of the shallow dishes. Persons are stationed to observe when a small film appears upon the water in the dishes, when the contents of several are mixed together, and thrown over the other dishes. This operation increases the congealing process; as a state of calmness has been discovered by the natives to diminish the quantity of ice produced. When the sky is quite clear, with gentle steady airs from the N.N.W., which proceed from the hills of considerable elevation near Bheerboom, about one hundred miles from Hooghly, the freezing commences before or about midnight, and continues to advance until morning, when the thickest ice is formed. I have seen it seven-tenths of an inch in thickness, and in a few very favourable nights the whole of the water is frozen, when it is called by the natives solid ice. When it commences to congeal between two and three o'clock in the morning, thinner ice is expected, called paper ice; and when about four or five o'clock in the morning the thinnest is obtained, called flower ice.

Upwards of 250 persons of all ages are actively employed in securing the ice for some hours every morning that ice is procured, and this forms one of the most animated scenes witnessed in Bengal. In a favourable night upwards of 10 cwt. of ice will be obtained from one bed, and from twenty beds upwards of 10 tons.

When the wind attains a southerly or easterly direction no ice is formed, from its not being sufficiently dry; not even though the temperature of the air be lower than when it is made with the wind more from a northern or western point. The N.N.W is the most favourable direction of wind for making ice, and this diminishes in power as it approaches the due north or west. In the latter case more latitude is allowed than from the N.N.W. to the north. So great is the influence of the direction of wind on the ice, that when it changes in the course of a night from the N.N.W to a less favourable direction, the change not only prevents the formation of more ice, but dissolves what may have been formed. On such occasions a mist is seen hovering over the ice beds, from the moisture over them, and the quantity condensed by the cold wind. A mist in like manner forms over deep tanks during favourable nights for making ice.

Another important circumstance in the production of ice is the amount of wind. When it approaches a breeze no ice is formed. This is explained by such rapid currents of air removing the cold air before any accumulation of ice has taken place in the ice beds. It is for these reasons that the thickest ice is expected when during the day a breeze has blown from the N.W., which thoroughly dries the ground.

The ice dishes present a large moist external surface to the

dry northerly evening air, which cools the water in them, so that, when at 61° it will in a few minutes fall to 56°, or even lower. But the moisture which exudes through the dish is quickly frozen when the evaporation from the external surface no longer continues radiative; a more powerful agent then produces the ice in the dishes.

The quantity of dry straw in the ice beds forms a large mass of a bad conductor of heat, which penetrates but a short way into it during the day; and as soon as the sun descends below the horizon, this large and powerfully-radiating surface is brought into action, and affects the water in the thin porous vessels, themselves powerful radiators. The cold thus produced is further increased by the damp night air descending to the earth's surface, and by the removal of the heating cause, which deposits a portion of its moisture upon the now powerfully radiating, and therefore cold, surface of the straw, the water, and the large moist surface of the dishes. When better radiators of heat were substituted, as glazed, white, or metallic dishes, the cold was greater, and the ice was thicker, and the dishes were heavier in the morning than the common dishes. Any accumulation of heat on their surface from the deposit of moisture is prevented by the cold dry north-west airs which slowly pass over the dishes. The wind quickly dries the ground, and declines towards night to moderate airs. The influence of these causes is so powerful that I have seen the mercury in the thermometer placed upon the straw between the dishes descend to 27°, when 3 feet above the ice pits it was 48°.

So powerful is the cooling effect of radiation on clear nights in tropical climates, that in very favourable mornings, during the cold season, drops of dew may sometimes be found congealed in Bengal upon the thatched roofs of houses, and upon the exposed leaves of plants. In the evening the cooling process advances more rapidly than could be supposed by one who has not experienced it himself, and proves the justness of his feelings by the aid of the thermometer. In the open plain on which the ice is made, I have seen the temperature of the air, 4 feet above the ground, fall 70·5° to 57°, in the time the sun took to descend the two last degrees before his setting.

The tropical rains are succeeded by the cold season, when the night is cold, the sky quite clear, and the air becomes a bad conductor of electricity, from the dry northern winds which then prevail. This is proved by the rapidity with which evaporation proceeds, by the dispersion of clouds, and by the more evident proofs which the hygrometer exhibits. During the cold season vegetation proceeds, and electricity continues to be evolved by living bodies, and during their decomposition.

These remarks will enable us to explain the process by which the ice is prepared in Bengal.

1st, The large quantity of dry straw and moist dishes rapidly become cold, by their powerfully radiating surfaces, at the same time that the large body of dry straw strongly attracts positive electricity, and the descending currents of air deposit moisture in the dishes of water. Hence, during a cold and clear night, with airs from the N.N.W., the cooling process will advance more rapidly in proportion to the non-electric or attractive nature of the body, which with the radiating power of the surface, regulates the cold and the quantity of dew deposited upon the body.

2nd, The high and dry situation and free exposure of the ice fields to the sky, and the absence of all causes which could interrupt the influence of the large body of non-electrics, and the extensive surface of powerful radiating substances, sufficiently account for the degree of cold produced in the ice plates; and

3rd, The cool, dry north-west airs slowly pass over the ice beds, absorbing the accumulation of moisture and of heat, which is given off by the liquefying of a large quantity of water that would otherwise accumulate over the beds; and, thus retaining the air clear and dry, allows the full operation of the other causes, particularly radiation.—T. A. Wise.

[This method of obtaining ice seems to have been practised by the Israelites in the time of Josephus, for he mentions "the ice which the inhabitants of the country make during the summer."—(Dr. Bello Jud., iii., 10.)

It may be useful also to mention that if 1 lb. of sulphuric acid (oil of vitriol) is mixed with 1 lb. of water and allowed to become cold, and then 2½ lbs. of powdered crystals of sulphate of soda (Glauber's salt) are added, the operation being carried on in a cold place, the temperature of the mixture will sink to several degrees below the freezing point of water. The whole costs but a few pence.—Eds.]

VISIT OF THE ROYAL HORTICULTURAL SOCIETY TO BIRMINGHAM.

A public meeting was held in the committee room of the Town Hall, on the 18th inst., for the appointment of a local committee and making other arrangements for promoting the Exhibition of the Royal Horticultural Society in Birmingham in the month of June next. Mr. Alderman G. B. Lloyd (Ex-Mayor), occupied the chair. Mr. Marshall, a member of the Society's Council, and Mr. Richards, Assistant Secretary, attended as a deputation.

Mr. T. B. Wright before moving the first resolution, mentioned that letters of apology for non-attendance had been received from many gentlemen and gentlemen's gardeners. He said it was very satisfactory to find that so many noblemen's and gentlemen's gardeners were willing to render assistance in carrying out the undertaking which had brought them together. He had pleasure in moving, that the meeting having heard with much satisfaction that the Council of the Royal Horticultural Society had accepted the invitation to hold their next country meeting in Birmingham on the 25th, 26th, 27th, 28th, and 29th June next, pledged itself to co-operate in all the arrangements which might be necessary to promote the success of this its first visit to the district. They had on two former occasions met in that room to co-operate with local committees appointed to render the visit of the Royal Agricultural Society to towns not far distant from Birmingham as successful as possible. In 1859 the Society held its show at Warwick, and in 1871 at Wolverhampton; and in both instances the appeal to the town was met in a very liberal manner. On the present occasion Birmingham was the actual scene of operations, and instead of co-operating with a committee, they were met that day to appoint a local committee which would take the management of all the arrangements of the forthcoming visit. The inhabitants of Birmingham were glad to assist the Royal Agricultural Society, and he was of opinion they would show the same spirit of liberality towards the sister Association—the Royal Horticultural Society. On the former occasions to which he referred, the sub-committee merely took in hand the work for the town; but in the present instance their work would be not only in Birmingham, but in other towns besides, and sufficient evidence would be laid before them to show that they would have a very wide gathering ground, which, with an exceedingly influential committee, would, he thought, render it pretty certain that the visit of the Society next June would be successful. He hardly felt it necessary to say anything with regard to the operations of the Society. Some years ago it might, perhaps, have been thought to be aiming a little too high to exercise much influence upon the owners of ordinary gardens; but the Society had year by year become more and more useful; and it was a happy thought when the Council determined to hold their shows in different parts of the country, as that course would not fail to lead to the most satisfactory results with respect to the progress of horticulture. It would be remembered that the Society formerly held its provincial shows at the same time and place as the Royal Agricultural Society; but great difficulties were found to be inseparable from such an arrangement, principally because many persons found so much to occupy their attention in the grounds of the Royal Agricultural Society that they could not attend the show of the Royal Horticultural Society. Last year the first independent meeting of the Royal Horticultural Society was held at Nottingham, and was most successful. After its termination some correspondence with regard to the place for the holding of the next meeting took place between the Council and Mr. Quilter, and the result was that the Council determined the next show should be held at Birmingham. Mr. Quilter met the Council in a very liberal manner, and they were satisfied that no better spot than the Lower Grounds, at Aston, could be found; and that there was no other place in the vicinity of Birmingham where people were likely to attend in greater numbers. After this year the plans of the Society for the future would, he expected, be permanently decided upon, and arrangements made by which every part of the kingdom would be visited in its turn, and under these circumstances they might look forward, in six or eight years, to again welcoming the Society to Birmingham. With regard to the arrangements respecting exhibitors and subscriptions for admission, these would be made public in due time. They would, he was sure, be found to be on a very liberal scale. One duty which the local committee would have to discharge would be to raise a fund for providing special prizes to supplement those offered by the Society. For all other money subscribed full value would be received. In other places where exhibitions of this kind had been held, a large sum had to be raised in order to put the grounds in proper order. Nothing of the kind would be required in the present instance, for that would be undertaken by Mr. Quilter. From what he knew of the success which had

attended other exhibitions in Birmingham, he thought the Royal Horticultural Society could not have adopted a wiser resolution than that in which they determined to pay a visit to the town. The large exhibitions held here had taught many people the way to Birmingham, and he hoped the railway companies would be as liberal on this as they had been on other occasions.

Mr. Bragg seconded the motion. He said not only had they great pleasure in welcoming the Royal Horticultural Society; the Society had equal pleasure in accepting the offer of the people of Birmingham. From his knowledge of matters of this kind he ventured to say that the printed list of the local committee, if he might make the comparison, was superior in quality and numbers to any committee which the Society had previously had to assist them in their exhibitions. They felt they were about to achieve a success, and he hoped the meeting that day would come forward and supplement the ordinary handsome premiums offered by the Society.

The resolution was carried unanimously.

Mr. E. W. Badger having read a large number of letters from noblemen, gentlemen, horticulturists, and others, expressing their willingness to allow their names to appear in the list of the local committee,

Mr. Councillor E. Tonks moved that the noblemen and gentlemen whom he named, with power to add to their number, be appointed the local committee. He said the names had been most carefully selected, and therefore the meeting could not do better than adopt the list in its entirety. From what he could hear, the grounds upon which the exhibition would be held would offer a better opportunity of display than any site the Royal Horticultural Society had yet occupied.

The motion was carried.

On the motion of Mr. C. J. Perry, seconded by Mr. J. E. Mapplebeck, it was resolved that the Earl of Bradford be respectfully requested to accept the office of President [This he has done], and his Worship the Mayor of Birmingham that of Vice-President of the committee.

On the motion of Mr. Cartland, seconded by Mr. Vertegans, Mr. Councillor Lowe was unanimously appointed honorary treasurer.

Mr. Lowe proposed that Mr. E. W. Badger be appointed honorary secretary to the local committee. He said Mr. Badger had taken up the business in an earnest manner, and being a lover of horticulture and floriculture, he was the most valuable assistant they could have.

Carried *nem. con.*

Mr. Hallam said, that notwithstanding the very excellent appointment they had just made, there would be much work to be done, which would require the services of a paid secretary, and he therefore begged to propose the appointment of Mr. Alexander Forrest, which was carried.

Mr. Councillor Lowe moved that a subscription be entered into for the purpose of raising a special fund to supplement the prizes offered by the Society, and it being important that the list should be prepared without delay, the secretary be authorised to issue a supplementary circular. He said a great deal would depend upon this resolution, inasmuch as it had hitherto been the practice to raise a very considerable sum for the purpose of giving special prizes. The people of Nottingham managed to raise between £700 and £800. In Birmingham they had always been able to raise a good sum when it was required, and he hoped in the present case they would prove themselves at least equal to Nottingham, which they looked upon as a little village compared with Birmingham. He hoped that the amount subscribed would be so substantial as to render the invitation which would be given to exhibitors a strong one. There would be no difficulty, in his opinion, in obtaining £700 or £800, and he was equally certain that the committee would distribute it wisely. He believed he was correct in saying that not a halfpenny of any money which might be raised would go towards defraying expenses, and that the whole of the money would be given in special prizes. He trusted that a leading prize of £50 or £100 which had a decided Birmingham character, and which would be a novelty, might be given. Birmingham was noted for successfully carrying out great exhibitions of a national character, and he believed if the town and neighbourhood acceded to the proposal contained in the resolution they would have a thorough good prize list, and a successful meeting.

Mr. E. W. Badger seconded the motion. He said that with a large special prize list there would be no difficulty in making the visit of the Royal Horticultural Society a successful one. Indeed, had it not been the general impression of those who knew the feeling of residents in this locality that a large special fund would be raised, he did not think they would have entertained the idea of inviting the Society to come here at all. On all occasions when a good object had been properly put before the people of Birmingham and the district it had always been well supported. An object, like that connected with the visit to a town which is the central point of a large population resident in the counties of Warwick, Worcester, and Stafford, must necessarily be of importance to those who thought that horticulture had anything to do with the welfare of a people. The benefits attending a knowledge of horticulture and floriculture were incalculable, and one of the great objects of the Society was to foster a love for it, and extend knowledge concerning it. It was the bounden duty of all who felt as he did about the matter to give the Society the warmest welcome. He was satisfied they would do so in Birmingham. The interest which was first excited by the prospect of the visit had already been greatly augmented. The special work which lay immediately before them was to raise a sufficient sum to enable the committee to issue an attractive schedule of prizes to supplement that of the Society. They ought at least to raise in Birmingham as much as was contributed by the Nottingham people. There £750 was raised, and was subscribed almost entirely in the town, Lord Belper heading the list with a donation of £25. The total contributors numbered something like two hundred gentlemen. It had been strongly urged that the names of the donors should be given in an independent subscription list, and that the sub-committee who would draw up the special list of prizes should deal with the money as they thought fit. This would relieve donors from a great difficulty, and would secure homogeneousness in the prize list. At the same time, of course, where donors particularly wished to decide the destination of a subscription, their wishes would be carefully attended to. The resolution was carried.

Mr. Marshall, one of the deputation from London, said himself and Mr. Richards had attended that day in order to hear the views of those present. He presumed that every gentleman was more or less interested in horticulture, and therefore acquainted with the object for which the Society was instituted. That object, briefly stated, was to promote horticulture in all its branches. They had a great deal of trouble at the outset, but that had been got over in a very successful manner. The London shows having appeared to pall upon the public, it became necessary to make a stride, and so the Council determined to visit all the towns in England where any encouragement might be held out to them. At the outset it was considered necessary to join the sister Society, and visit the towns fixed upon by it. The year before last, however, some little discontent was expressed that there was so much to be seen at the Royal Agricultural show that visitors had no time to visit the Royal Horticultural show, and so the latter Society determined last year to go upon its own merits. The first attempt at Nottingham was a great success, and fully justified the resolution to which the Council had come. He could only hope that the show would be equally successful at Birmingham, and from what they had seen he had not the slightest doubt that such would be the case. The officers of the Royal Horticultural Society would not trouble the local committee to do much in connection with the arrangements, as they would look to that themselves; and the main duty of the committee would be the formation of a special prize fund. Of course the committee were far better acquainted with local interests and requirements than persons coming from a distance, and therefore the collection and appropriation of the subscriptions would be left entirely in their hands. The local prize fund should not be given, if possible, for any particular object, as that would interfere with the arrangements of the show. If a certain sum of money was placed in the hands of a responsible committee, they would be better able to divide it into prizes than if it was given by individuals for any particular hobby.

Mr. Richards, the other member of the deputation, said there was very little left for him to remark upon except with regard to the financial arrangements. The Council had had a preliminary meeting to decide upon the question of admission to the show, and they thought of fixing 10*s.* 6*d.* as the charge for the first day; 2*s.* 6*d.* for the second day; 1*s.* for the third and fourth days; and 6*d.* for the fifth. There would be a reduction of 3*s.* on tickets purchased beforehand for the first day, which would make the admission 7*s.* 6*d.* The subscription for the entire Show it was thought should be a guinea. Subscribers of one guinea, it was suggested, should have three single tickets for the first day, and four for the second day, but he thought they would have to discuss that hereafter, as the privilege contemplated seemed rather too large. For a subscription of 10*s.* 6*d.* a single ticket of admission, available on all days, but not transferable, would be given. Tickets for the third and fourth days should be sold to manufacturers for their workpeople, in packets of not less than fifty, at a reduction of 30 per cent. The financial result of the meeting at Nottingham was very satisfactory, the Society having cleared between £700 and £800. He could only say that with a large place like Birmingham they hoped to clear double that sum—perhaps more.

In answer to the Chairman, Mr. Quilter said the Society and himself undertook the whole expenses of the show. After the expenses had been defrayed they would divide the surplus equally between them. The establishment of such a place as the Lower Grounds had naturally been a source of great anxiety to him. He little supposed he should ever make it what it was, or that the public of Birmingham and the district would have

supported him in the manner they had done. Having attained the position which he had done, and his place having been honoured so far as to be selected for the show, he was very anxious it should be known that he did not embark in this undertaking for his own benefit. He intended to give to the charities of the town half of his share of the proceeds. He did so for the reason that the town should not only give a hearty and united support to the Society, as no doubt they would, and send it back with a good round sum of money to be devoted to the advancement of horticulture; but at the same time prove that they had not forgotten those noble charities of which they were justly proud. He wished this to be distinctly understood, because some persons thought the speculation was simply a money-making one with him.

In answer to Mr. Cartland, Mr. Richards said the proposal as to admissions which he had read was merely a sketch, and at present in embryo only.

Mr. Wright, alluding to the regulations with regard to the tickets, said he thought the Council of the Cattle Show had adopted the wisest plan, after studying the regulations of every society in England. They had had experience of the advantage of promoting the sale of tickets beforehand. The subscribers of £1 received six single tickets, all of them being available for the first day, when the charge for admission was 5s.; but it was found that not more than half went on that day, the other half going in on the 1s. days. He thought the same principle should be adopted at the forthcoming show, and that a very liberal return for subscriptions should be given. For a guinea subscription three tickets should be issued for the first day; four for the second day; and for the Thursday and Friday thirty tickets for £1, and fifteen for 10s. Looking at the extent of the grounds and their great popularity, and the advantage of being within easy reach, he thought they had better go on a liberal scale.

Mr. Wright next moved a resolution to the effect that every encouragement be given for the exhibition of horticultural implements and appliances, garden ornaments, and articles generally which are applicable for use in the several branches of rural economy. He said that at previous shows this department had not always been successful, as it had been found that when the meetings of the two great Societies were held together many of the implements used in horticulture were in the showyard of the Royal Agricultural Society. Now, however, that the shows were held independently of each other, there would no doubt be a good collection, the more so as he believed the promoters of the department intended to act very liberally towards the exhibitors, remembering the old saying that "if there were no exhibitors there would be no exhibition." The regulations had satisfied Mr. Lowe, who, he might say, was an authority on such exhibitions; and, therefore, he hoped that other manufacturers would combine and make the show not only one of large extent but also one of great interest.

Mr. J. Cartland seconded the resolution, which was carried.

It was proposed by Mr. Quilter, and seconded by Mr. E. W. Badger, that a memorial be presented to the Directors of the London and North-Western Railway, asking them to erect a temporary station at Witton Bridge for the accommodation of the show.

This motion was also carried.

At the close of the meeting subscriptions to the amount of about £130 were announced.—(*Midland Counties Herald.*)

CONIFERS WHICH HAVE SEEDED AT BICTON,

AND THE MODE OF RAISING THEM FROM SEED.

The plan we adopt here with rare Conifers is to have clean pots or pans well drained, and filled with sandy loam or other suitable soil, to cover the seeds carefully and not too deeply, and to finish with fine soil, which we firm equally. We then plunge the pots or pans near the glass in finely-sifted cinder ashes under cold frames or pits. The surface of the soil is kept in proper condition as respects moisture, neither too wet nor too dry; we also keep the pit or frame close until the seedlings appear, after which we gradually harden them off, and in due time remove the lights altogether. By the 1st of July, if the seed has been sown in March, the seedlings may be transplanted into boxes, after which we shade them for a few days, and then inure them to light, attending to careful and regular watering during the summer and autumn months.

The pots or boxes should be protected from frost during winter; this can be done in a cold frame or in a sheltered corner in the open air, where they should be well covered with dry fern, so that no frost may penetrate to the roots. Leaf mould free of sticks is also a good material. Supposing the winter to have been passed safely, and that March has come round, transfer the stock to nursery lines, where the plants will soon give a good account of themselves if placed in a good position in sandy loam. They should be transplanted annually for two or three years, after which they should be planted out in selected spots where the soil has been properly prepared for their reception.

Conifers of which large quantities of seeds ripen here every season—such as Picea nobilis, P. cephalonica, &c.—are sown in prepared beds in the open air, and grow freely in this way; they remain in seed beds for twelve months, after which they are planted in nursery lines as before stated.

Cedrus Deodara has coned for several years past, but there are no fertile cones as yet. This year cones have been produced, but I have been unable to discover any pollen on the trees.

Cunninghamia sinensis has coned for several years, but has not proved fertile as yet.—R. Begbie, *Bicton Gardens.*

USEFUL FOREST TREES OF INDIA.

Very voluminous returns have recently been issued among the parliamentary papers, naming the trees and showing in detail the progress of the new system of forest administration.

The three principal sorts of trees in the old forests are Teak, Sál, and Deodar.

The papers prepared for parliament give the reports of the twelve forest administrations on the operations of the financial year 1869-70. The report from British Burmah shows that, of the total area of 60,000,000 acres, there are 1,534,000 acres of Teak-producing forests, and 2,946,000 acres of forest void of Teak, besides 26,000,000 acres of low-lying forest land and land occupied by 12,845 towns and villages. The yield of timber from British forests in the year was 53,395 logs, 39,843 tons, and the surplus of the year's operations was £50,934. The Pegu division is the largest and most important. The average age of a first-class tree of 6-feet girth in this division is found to be 124 years.—(*Times.*)

ARECA RUBRA.

This is a free-growing, tolerably hardy Palm, and for these reasons I wish to especially draw the attention of amateurs to it. It is admirably adapted for the decoration of the dinner-table, the drawing-room, the hall, and of the open grounds during the summer months, as, indeed, are all Palms, from their readiness to grow and their power to withstand the evil consequences of the dust arising from our sea-coal fires. The genus Areca is widely distributed, being found in both the East and West Indies, Australia, and, as in the case of the species now under consideration, in the Mauritius and surrounding islands. One East Indian species (A. Catechu), yields the famous "Betel Nut," which is chewed with such gusto by the natives; and A. oleracea of the West Indies is the famous Cabbage Palm—one of the vegetable wonders of my schoolboy days.

Areca rubra is a quick-growing plant, rising upon a somewhat slender stem; the leaves are long, pinnate, sheathing at the base, with long, narrow, and slightly recurved pinnæ; the colour in a young state is a beautiful crimson red, changing to a bright green as the plant grows older, though the midrib of the pinnæ and the sheathing petiole, however, still retain a deep red colour, which, combined with its beautiful plume-like aspect, should render it a favourite of all admirers of ornamental-leaved plants. The species is propagated from seeds sown in strong heat and grown on in a stove temperature for the first year or two, by which time they will have become handsome young plants. If required for the decoration of the greenhouse or the drawing-room, it will be advisable to inure them gradually to a cooler temperature; but should they be wanted for the decoration of the stove or for exhibition purposes, then do not on any account give them a check.

Areca rubra.

The soil in which the Areca rubra thrives best, is that composed of equal parts of peat and loam with a little sand, to which a little more loam may advantageously be added when the plants have attained some size. The pots should be well drained, and the plant in summer should have a liberal supply of water both from the watering-pot and syringe.—Experto Credde.

AMONG THE CONIFERS.—No. 2.

The formation of the pinetums at Dropmore, Bicton, and some other places has done much good by drawing attention to the culture of Conifers, and has laid a solid foundation for others to build upon. That their teaching is thoroughly

appreciated is shown by the numerous fine examples of the best known varieties now common to most gardens. The graceful forms are constantly to be met with, and one cannot but admire them wherever they are seen flourishing. With this feeling of admiration, however, comes the thought, Have Conifers yet found their right place in gardenesque scenery, and have we fully realised all that is capable of being effected by the skilful arrangement of the beauties possessed by this large natural order? I think that such is not the case, and purpose devoting the present paper to the consideration of this important part of my subject.

With many of the choicest varieties wonderfully rich and distinct effects may be secured in extensive shrubberies, as well as in park and landscape scenery generally. Mark the effect produced by a group of solemn Pines fringing the brow of some high hill, and then try to imagine that which a grove of Deodars would present on its steep slopes. What so suitable for such a purpose as the Deodar? The sweep of its pendant branches makes it as suitable a tree for covering the steep hill side or fringing a mountain torrent, as it is for adorning our lawns and pleasure grounds.

In advocating the more extensive introduction of Conifers I do not mean to ignore the merits of such noble deciduous trees as the Oak, the Beech, the Elm, or the graceful Birch, so beautiful in winter. These are far too valuable ever to be set aside. But I think the two classes may be advantageously blended together.

The form and extent of dressed grounds very much affects the way in which Conifers should be arranged in them. Great attention should be given before deciding upon the number of plants and the most suitable varieties. In many instances more plants are used than there is any necessity for, and a confused crowded aspect is imparted to what, with a little judicious management, might have been a graceful and enjoyable scene. It may be useful to quote a simple instance or two by way of illustration. On a small plat of grass in front of a pretty villa I once saw a single plant of Araucaria imbricata in good health and of most handsome proportions; a few groups of Roses and other flowering plants were tastefully dispersed around upon the turf, but as there was no other plant of the same species to detract from its appearance, the effect was singularly pleasing. In contrast to the chaste simplicity of this scene take another. On some turf very similar in size and position, a number of Conifers of various kinds were planted in straight rows, causing it to look more like a portion of a nursery garden than a villa lawn. It is unnecessary to dwell upon this lesson further than to observe that it is applicable in the case of the most extensive gardens. It is best, therefore, in grounds of no great extent, to keep to a few choice kinds planted singly, or with other shrubs, upon the lawn in suitable positions. In selecting kinds for such a purpose, care should be taken to choose those of established merit and distinct appearance. If six were wanted I would choose Cupressus macrocarpa, Picea Nordmanniana, Picea Pinsapo. Thujopsis borealis, Cedrus Deodara, and Araucaria imbricata, If a dozen, I would add Juniperus chinensis, Thuja Lobbii, Wellingtonia gigantea, Pinus insignis, Cupressus Lawsoniana, and Taxodium distichum. These are all distinct and excellent species, but to do full justice to them a considerable expanse of turf would be required.

Araucaria Imbricata at Piltdown.

In large gardens I am sure that grouping may be carried to a greater extent than it has hitherto been done, judging from what I saw during a visit to the nursery of Mr. Mitchell at Piltdown. The many kinds o Coniferæ cultivated at this nursery are remarkably healthy and vigorous, and a clear idea of their relative value can easily be obtained from the number there associated. The Araucaria, however, was the one which particularly attracted my attention. For some way along each side of a broad walk are rows of this tree, all of them symmetrical, but some notably so. I remarked a fine specimen about 30 feet high, which has its branches so regularly arranged as to render it conspicuous even among the others. Another large plant is a strange yet beautiful object, having long twisted arms closely set with spinous leaves, but presenting a naked appearance from the absence of any lateral growth. Many of the lower branches spring out fully 10 feet from the bole, twisting in a singular and not ungraceful manner, so as to stamp the tree as being almost a distinct variety. At the entrance of the avenue stands by far the finest specimen I have ever seen (of this we give a figure). It is a vigorous tree, 45 feet high, and beautifully clothed with branches from the base upwards. What an attractive feature an avenue or a group of such fine trees would form.

Mixed groups and borders are common enough, and generally do not fail to please the eye; but if Conifers were introduced in masses, I think some additional beauty might be gained. Thus, besides a grove of Araucarias, there might be others of the lofty Abies Douglasii, the rich green Cupressus macrocarpa, Wellingtonia gigantea, and such Pinuses as ponderosa, the glaucous macrocarpa, and the bright green insignis. Many other species of Conifers might be quoted as being equally suitable for such a purpose, and with these individual taste can vary the list so long as it confines itself

to these sorts which possess distinct form and colour.—Edward Luckhurst.

WINTER CULTURE OF THE ROSE TREE.

Now-a-days Perpetual Roses flower in the open ground as well towards the end of October as they do in the spring. In the immediate neighbourhood of Lyons the temperature has not yet sunk below 32° F., and in spite of the nearness of lofty snow-girt hills, which chill the moisture of the atmosphere, the cold is more piercing than severe. The leaves of Roses do not commonly fall until after a frost of from 5° to 7° F., and even then they are not longer than a fortnight in making their re-appearance if the weather turn milder. The plants themselves do not like either heat or cold in excess, but rather a temperate and circulating atmosphere; and do not show their proper fullness, freshness, or shade of colouring in any other season but the spring and autumn. It is then that the Teas, and more especially the Noisettes, come forth in all their true beauty.

We are at this very time (November) potting-off Roses for winter-flowering in the greenhouse, but in so doing we have to be careful which we select for that purpose, as forcing does not agree equally well with them all. Those which do not thrive under such treatment are Jules Margottin, Mme. Moreau, Rose du Roi, La Reine, Lion des Combats, Toujours fleuri, Achille Gonot, and the numerous class of Géants. Others show themselves less insusceptible of forcing, and such are the Teas, the Noisettes, and the Fles Bourbons. Among these there are Mme. Falcot, de Safrano, de Sombreuil, and Gloire de Dijon, from all of which some pretty flower for a bouquet may be obtained. Bengals succeed best as forced plants, and particularly Hermosa, Cramoisi supérieure, and Prince Charles. There are certain varieties which flower well in vases, but their branches stretch out and straggle about too much to form a fine head, though they do excellently as cut flowers. Of these Ludovic Letault, whose flower bud is like that of Cent-feuilles, is one.

In November and December slips or grafts should be taken from a fine well-rooted plant, placed in 5 or 6-inch pots containing neither too sandy nor too clayey a soil, watered in order to settle the earth, and two days afterwards sunk somewhat deeply in the open garden. There let them remain for a year, and in the following November or December lift, clean, and carry them into a hothouse, where a bed of tan, so regulated as to begin heating shortly after their insertion in it, is prepared. Heat the house gradually, and water and besprinkle the plants moderately, taking care o give them snatches of air whenever the sun reappears. Insects, which will not be backward in making their presence known, should be treated with the fumes of tobacco. Should there be any signs of flagging, water the base of the Rose once or twice with water slightly tainted with "purin" or guano; but be very cautious not to use it too highly nitrogenised, or else it will cause the roots to rot instead of strengthening them.

Six weeks in the hothouse is about the time required for bringing the Roses into flower, and after their blossoms have been all gathered for decorative purposes, they may be removed to a cold or temperate house until the spring, and then planted out of doors to take their chance. This is not always a favourable one, especially during the summer. When there are several houses devoted to this kind of culture, three or four successions of forced Roses can be produced, between each of which a difference of temperature should be kept up; thus, the second and third houses should have temperatures varying from 60° to 68° F., when the first batch is beginning to go off.

Pits can be used for forcing Roses instead of greenhouses, they should be heated by means of a good bed of horse droppings fresh from the stable, over which a thick coating of light earth or sand is spread, wherein the pots are plunged, the whole being covered at night, and upon foggy and very cold days. It is in this way that spring Roses are prepared for sale in the markets before those out of doors have come into flower. In this case Roses recently potted in November or December can be used, and not those of the preceding year. The forcing of them in a greenhouse for the spring is the same.

We think that our way of forcing Roses is an immense stride in the art of cultivation, when the Romans knew of it more than two thousand years ago. History tells us that the Egyptians, who were still at the front of civilisation, sent the Emperor Domitian as an invaluable gift, a bouquet of Roses in the winter time; but this token of deference was received by the court with a contemptuous laugh, so plentiful was the flower at that period in Rome. Martial says, "The sweet scents of spring time are wafted about the streets, and lavish flowers, in garlands woven, strike with dazzling lustre upon the eye. O Egyptians! do you send us corn, and we will give you Roses in return." During the public games the ediles would send crowns of Roses to senators and other persons of repute, and a similar adornment was, on the occasion of her marriage, laid upon the forehead of the bride. Guests at banquets quaffed the old Falernian in goblets crowned with Roses, and the same seductive flower diffused its perfumes from the tables and the couches on which the guests were lying. Even the streets were sometimes, according to Charles Malo, strewn with Roses. To obtain them during the winter the Romans used to heat their conservatories with boiling water.

But long before this the Greeks had carried the cultivation of the Rose to a high pitch. They wore it on their heads, decorated their furniture, and perfumed their wine with it. During the war of Cerra, so great became the sensuality of the Lacedemonian troops, that they did not care to drink any wine but that which was perfumed with Roses. The kings of Bithynia used to recline upon pillows embellished with the Rose; and the Jewish priests, in their great ritual, had their heads encircled with it. The taste for this flower ran to such an immoderate height during the times of Paganism, that a reaction took place with the introduction of Christianity, and we find Tertullian and Clement of Alexandria declaiming against Roses, because the crown that Christ had worn was one of thorns.

But this was only a fleeting shadow of bitterness and sorrow. The chaste and beautiful Rose soon reasserted her claims to the devotion of every kindly heart and noble spirit. The frequency of its usage in the rites and feasts caused such pleasure, that the serious Christians did not hesitate to admit it in their celebrations. The papacy created an order of the Golden Rose, and then the simple and odorous Eglantine became the prize of the floral games.—(*La Belgique Horticole.*)

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of this Society for the present year was held at Burlington House on New Year's evening, when, notwithstanding the attractions of the festive anniversary, there was a good attendance of the members. Among the donations to the Society's library received since the last meeting were the fifth volume of the "Catalogue of Memoirs," published in the Transactions of all the learned societies, issued by the Royal Society, one of the most elaborate and useful works ever published; together with the usual periodical works treating upon entomology.

The Secretary said he had received communications from Professor Newton, and Messrs. H. Doubleday and J. Gould, relative to the destruction of dragon flies by birds, the last named gentleman stating that the hobby and kestrel feed on those insects, and that smaller birds will readily attack the smaller blue dragon flies commonly seen about rushes growing in running streams. A letter was also read from Mr. Riley, the official entomologist of the State of Illinois, stating that the whole of the valuable collections of the late Mr. Walsh had been destroyed in the fire at Chicago, and Professor Westwood stated that of Mr. Stimpson, being by far the largest collection of Crustacea ever formed, had also there perished.

Mr. Miller called attention to a recent statement of M. Emile Joly, published in the Memoirs of the Academy of Cherbourg, to the effect that the genus of supposed Crustacea founded by Latreille under the name of Prosopistoma is probably only the immature condition of Conis, one of the genera of Ephemeridæ.

A memoir was read by Mr. A. Butler containing descriptions of some new exotic moths of the group Pericopedes; and Mr. F. Smith read a letter from Mr. J. T. Moggridge, on the habits of some species of ants belonging to the genus Aphenogaster, observed at Mentone, at the end of last October and beginning of November. These ants harvest the seeds of various plants in chambers, sometimes excavated in solid rock beneath their nests. He had seen them busily engaged in conveying the seeds into their chamber, and found that in most cases they gnawed off the radicle to prevent germination, but he had also observed sprouted seeds being brought out again, as apparently unsuited for storing purposes. Many of these seeds had their contents extracted through a hole on one side; and though he had not seen the ants actually feeding on them, he was inclined to believe that the stores were made for the purpose of supplying food during the winter season, whilst the ants, although not dormant, were confined to their nests. It was stated that Colonel Sykes had communicated a memoir on this subject to the Society many years ago, proving that certain Indian ants store up grain for food during winter, and have the instinct to bring what remains unconsumed to the surface to dry it after the closing storms of

the monsoon, thus confirming the assertion of Solomon (Prov. vi. 7), which had been doubted by some northern naturalists ignorant of the manners of the species in warm climates.

SOME OLD AND NEW FUCHSIAS.

I HAVE not the intention of sending you a critical account of all Fuchsias, and particularising every good one—no such ambitious project is mine. I merely think I can pen a few lines on some that I, who have been a Fuchsia admirer and cultivator for several years, have found worthy of attention.

First, then, let me start with the double white corollas. There is a very beautiful one sent out by Mr. Cannell, and I think raised by Mr. Bland, in 1870. This is one of the best of the section, as the flower is good in style; a fine large flower, tube and sepals very bright in colour, and the corolla very double and of a pure white. There is an older variety, Vainqueur de Puebla, which is also exceedingly good. These I should place in the front rank. Empéreur des Fuchsias is a fine large flower, but the tube is too pink in colour, and the corolla not of a good-enough white to suit my taste.

Of the varieties with single white corollas an old one, Conspicua, is, I think, as good as most. It is a good, large, well-reflexed flower, the corolla a good white, and the tube and sepals a very good red. It has a peculiarity in often bearing flowers with five or six sepals, and I recollect once noticing one monstrosity with eight sepals. Another very good one is Picturata, not a very large flower, but having a beautifully pure white corolla. I have, and have had, many others of this section, but none that I think equal to these two. Next in order I will take white tubes. One of the best of these is Annie, an old kind, but yet one of the best. Beauty of Clapham is a very handsome flower, very large, but the tube is not pure white. Madame Menoreau, a continental introduction of three or four years ago, is also a very large beautifully formed flower, but it has the fault of the tube not being pure white. Lustre is another very beautiful light variety, with which I think everyone ought to be pleased. The tube is very white, and the corolla very bright. Arabella, Blanchette, Elegance, Minnie Banks, and Rose of Denmark are also good varieties in the white-tubed division. I must not forget to mention a unique variety which is not much known, called Erecta. Instead of carrying its flowers in a drooping position it holds them erect.

I will next name a few good double dark sorts. Agamemnon, Marksman, Norfolk Giant, Alberta, and King of the Doubles, are all old favourites. Triumphans is a fine new variety of 1870 which Mr. Williams introduced, and there are, doubtless, several others in this class which are good.

Of the single dark-corolla'd kinds blue and mauve have progressed very much in quality lately. Roderick Dhu, Father Ignatius, Emblematic, Constellation, Beauty of Sholden, Mr. Disraeli, and Beauty of Kent are fine varieties, some new and some old; and of the darker plum, or blackish plum corollas, Light Heart, War Eagle, Enoch Arden, Aurora, and Marvellous are all good. But I would especially name one as being extra good—viz., First of the Day; it has a splendid corolla.

These are a few of the best, but I daresay there are plenty of others. Regalia, Cloth of Gold, Golden Queen, Golden Mantle are also beautiful variegated-foliaged varieties.—GEORGE W. BOOTHBY.

STRAWBERRIES.

I AM highly gratified to find a man of Mr. Gilbert's experience writing so highly of the Black Bess Strawberry. I quite agree with all he says about it, and repeat that it is a noble Strawberry, which must be more generally cultivated when known. No doubt you will bring to mind that I sent you, some weeks since, a note on its merits, but only a notice appeared in the correspondence column to the effect that you knew nothing of it, and asked for a few plants. The following week you noted that you were led to understand it was synonymous with Empress Eugénie, and I find by referring to the description of the latter variety in Dr. Hogg's "Fruit Manual," that some of the characteristics are the same as of Black Bess, thus:—"Fruit very large, irregular angular, furrowed and uneven. Skin of a deep red colour, becoming almost black when highly ripened. Seeds small, not deeply embedded. Flesh red throughout, hollow at the core, tender, very juicy, and briskly flavoured. Rather a coarse-looking and very large Strawberry, not remarkable for any excellency of flavour."

What does Mr. Gilbert say to this? Does it correspond with his Black Bess? It should be added that there are as many conical-shaped fruit as those of other shapes, especially after the first two or three pickings. I never found them, or at least very few, hollow at the core, and I call them excellent in flavour. It bears a striking resemblance to some of the new French Strawberries illustrated in Dr. Hogg's "Gardener's Year Book" for 1871. Not having it at hand I cannot say which.

I had Dr. Hogg Strawberry for the first time last year, so I cannot speak positively about it. I liked the few fruit I had of it, but the plant is certainly not stronger than British Queen, which grows by the side of it. I believe it to be of a weak constitution. One plant of Black Bess is as large as eight of either of them at the same age.—J. T., *Maesgwynne, South Wales.*

SELECT ROSES.

To the thirty-six Roses already named by me these may be added—La Ville de St. Denis, Madame C. Joigneaux, Madame C. Verdier, Madame Knorr, and Madame Charles Wood; Triomphe de Paris, Mons. de Montigny, and Gloire de Vitry, three fine old Roses; Alice Dureau, Dupuy Jamain, Madame Jacquier; Eliza Boëlle, like Mdlle. Bonnaire, but a better grower; Baron Chaurand, very handsome, black shaded; Lord Macaulay; Lord Clyde; Mdlle. Emile Boyau, like Madeline; Annie Wood; La Sœur des Anges; Prince Leopold, a fine pole Rose; Black Prince; Glory of Waltham, a fine pole Rose; Le Lion des Combats, lake; John Keynes; Frederick Biborel; Lord Herbert, very fine; Monsieur Noman.

Twenty-four of the Best Summer Roses.—Paul Ricaut, Paul Verdier, Madame Soëtmans, Charles Lawson, Coupe d'Hébé, La Volupté, Kean, Queen of Denmark, Boula de Nanteuil, La Ville de Bruxelles, Grandissima, Triomphe de Jaussens, Napoleon, Général Jacqueminot (H.C.), Tricolor de Flandre, Madeline; Œillet Parfait, beautiful, but dwarf and delicate; Juno, William Tell, Transon Goubault, Gloire des Mousseuses, Vandael, Crested Moss, White Bath.

Twelve Good Summer Roses.—Princesse Clementine, Common Moss, Lancii, Felicité Parmentier, La Seduisante, Charles Duval, Paul Perras, Persian Yellow, Blanchefleur, Frederick II., Chénédolé, and Brennus. The last three, Madame Soëtmans, La Ville de Bruxelles, Madame Plantier, Fulgens, Triomphe de Bayeux, and Lancii make good pole Roses. Summer Roses are good for long walks and glades, but should not be put with the autumnals. Tricolor de Flandre, Œillet Parfait, and Madeline are the only good variegated Roses we have, and they are beautiful.

Summer Roses are very hardy, suitable for the north, give a grand but short-lived season of bloom, and are very sweetly scented. You may back them for bouquets without injury.—W. F. RADCLYFFE.

MAKING A MUSHROOM BED.

THE old-fashioned ridge system of cultivating the Mushroom is an excellent one, and I have often obtained good and plentiful crops from beds formed on this principle. They should be 3½ feet in width and of the same height if intended for winter or early spring, and from 20 inches to 2 feet in width and height if meant for summer use. The great drawback is the long time that must elapse before the bed becomes ready to receive the spawn, and can be earthed-up and protected. I therefore choose for this purpose rather dry filmy material from old linings and hotbeds, which costs no time in preparing, and when firmly beaten into the proper form heats mildly and regularly, so that the spawn may be with safety inserted very shortly after the formation of the bed. The only drawback to beds of this kind formed out of doors, is the abundance of covering they require to keep in the heat, and the necessity of removing it at the risk of admitting the cold air whenever the Mushrooms are to be gathered. For these reasons I would recommend that the beds be formed under a shed where less covering is necessary, and where they can be examined at leisure.

For shallow beds in a Mushroom house, I prefer two parts of horse droppings, one of short litter, and one of dry fibry loam, but the materials mentioned before will also do for this purpose. I used to turn over the manure and let it get dry before mixing the loam with it, but now I think the object is attained just as well by throwing them together outside in a somewhat conical-shaped heap, and covering it with litter to keep off the wet. This, when it has so heated as to be white and dry in the middle, has the exterior removed, and is mixed with some fibry loam to make it firm. By this means a good

crop is obtained without a tithe of the trouble required in the other case, as less of the richness of the dung is expended than there is by the repeated turnings of the manure. A thatched shed shaded by trees is very desirable, but I have seen good returns, even in summer, from small ridged beds under the shade of trees. Mushrooms do best between the temperatures of 50° and 60°, but without these limits good crops may reasonably be looked for.—R. F.

"LES PROMENADES DE PARIS."

In resuming our notice of M. Alphand's great work we now come to that portion of it treating of the Bois de Vincennes, well known to those who have visited Paris as being on the east side of the city.

Avenue of Limes at Minimes.

The Bois de Vincennes forms part of what was originally the great forest of Lauchonia, extending from Melun to Paris along the right bank of the Seine. In the seventh century this was severed into three parts, which are now respectively represented by the Bois de Bondy, the Bois de Livry, and the Bois de Vincennes. This last is said to have been the first forest ever enclosed in walls, and the occasion of its being so was to preserve the stags, fallow deer, and roe sent by Henry II. from England to France.

The history of this, as of most forests near the capital, is that the Sovereign and the Court preserved it as chase or hunting-ground. A château was built there in the twelfth century, and from that time to the present it has been utilised to the varied requirements of the age and of the Court. It continued in the hands of the French Sovereign till 1792, when it became part of the national property; but in 1810 it returned to the Sovereign, and after undergoing many changes and vicissitudes it was in 1852 included in the civil list of the Emperor Napoléon III. In 1860 it became the property of the city of Paris, and then were begun those great works which, under the direction of M. Alphand, have resulted in an illustration of landscape gardening seldom to be met with, and the

production of one of the most important and beautiful public promenades of the French metropolis. Unlike the Bois de Boulogne, the Bois de Vincennes has the advantage of a stronger and moister soil, and was covered with large timber, which enabled M. Alphand to take advantage of the opportunity thus offered of cutting avenues and vistas so as to produce immediate effects. The two illustrations now given furnish representations of the manner in which this has been carried out, one being the Avenue of Limes, and the other the Chestnut Avenue at Minimes.

Chestnut Avenue at Minimes.

SMALL FARMS—HOW THEY CAN BE MADE TO ANSWER.—No. 6.

By Rev. William Lea, *Vicar of St. Peter's, Droitwich, and Hon. Canon of Worcester.*

STOCK FOR A FRUIT FARM.

As I am writing for the express purpose of advocating small fruit farms sufficient to employ one family with a little occasional help, this point must be borne in mind when the question of stock is considered. My ideal small farm, where it is to be had, is a mixture of grass and tillage—sufficient grass to keep three cows, and from three to five acres of tillage planted with fruit. Five acres should be the greatest extent; if it exceeds this it implies more hired labour than such a cultivator can afford.

I mention three cows, for I am told, knowing nothing of the subject myself, that cows are in inverse ratio to boys—we have a proverb in these parts, that one boy is a boy, two boys half a boy, three boys no boy at all. But with cows it is the reverse, one cow is no cow, two cows are half a cow—a doubtful advantage—but three cows are a cow, a very profitable investment. We will take, then, an ideal case, and suppose that there is sufficient grass land to keep three cows. How much this will be, will vary according to the soil; from three

to four acres of rich land to nine or ten of inferior land will be required. The wife will manage the dairy, and after making a good profit by the sale of butter and milk, will have plenty of this last produce left for her own children, who will grow on this diet to stalwart lads, able to do good service on the farm long before they are old enough to leave school. I have an idea that this milk question is an important one. It did not require the sad experience of the siege of Paris to prove how essential milk is for young children. Formerly it was readily obtained from the farm houses in country parishes, but now, I am told, there are but few at which it can be purchased; and where there is a difficulty on this score, I believe one of the most useful kinds of charity which any person could adopt, would be to keep cows for the purpose of selling milk to his poor neighbours. It would do far more good than any amount of money distributed in gifts or doles, which, as far as I can see, only tend to pauperise and destroy that spirit of self-respect and self-reliance which is so essential to the upward progress of a people. In addition to cows a few head of sheep should be kept on such a farm as I have described. They will eat the herbage which the cows have passed over. But cows and sheep can only be kept where there are some acres of grass, and as this will not always be the case, we will inquire what stock can be advantageously kept where the fruit farm is only tillage land from three to five acres in extent, and what buildings will be required to house it.

But before we house the stock we must consider how the owner of it should be housed. This is a very important matter; the character of the house has no inconsiderable influence upon that of its inhabitants, and where a whole family —parents, sons, and daughters—are huddled together in one sleeping-room, as is too frequently the case, all feelings of decency and self-respect are destroyed, and with them the fulcrum on which the lever for the upheaving of the family must rest. It is true that the cottager himself is often satisfied with his present accommodation, and in many cases if he were supplied with three bedrooms, would only see in this provision a reason for "taking in a lodger;" but we may hope that in a few years the Education Act will have produced a change of feeling in this as in many other respects, and that the labourer will not be contented with the wretched hovel in which he is now often obliged to live, but will demand, as a condition of his labour, a cottage in which the decencies of life can be observed, and a good-sized garden to counteract the attractions of the beershop, and to give employment for the spare time of the family.

In building a cottage certain well-known principles must be borne in mind; good drainage and proper ventilation are necessities, so is the provision of a certain number of cubic feet of air in proportion to the number of inhabitants. This last point is, I think, sometimes exaggerated, when it is maintained that the country cottage should contain the same number of cubic feet as the town dwelling or the prison cell, forgetting that the countryman and his family pass much of their time in the open air, and use the cottage principally as a sleeping-place. The point which I should consider as the most essential is, that there should be three separate bedrooms, or, at any rate, the means of providing them when required by the increase of the family—one for the parents, a second for the girls, a third for the boys. They may be small and rough, if you please, but they should be separate if any feelings of modesty are to be retained. My idea of a cottage for a fruit farm of from three to five acres would be this:—On the ground floor one living-room, about 18 by 13 feet (including the staircase), with a wash-house and back kitchen in one, 18 by 9, containing furnace, oven, &c; and on the upper floor three separate bedrooms. I think two good rooms below are better than three smaller ones, as I find that where there is a parlour, as it is called, it is seldom, if ever, used. If grass land is attached, a somewhat better description of house will be required; a small parlour may be added on, and a dairy of a similar size. I do not say that such cottages can be built to pay a high per-centage in the way of rent, but the extra money spent upon them will do far more good than if it had been given in doles.

So much for the cottage itself; the building to which the next point of honour should be given is the pigstye. The pig, as in Ireland, will be a material help in paying the rent; more than this, he will consume all the refuse vegetables, and tread the weeds and Potato haulm into manure, which is essential for the success of the farm. On such a take as I have described, one or even two breeding sows might be kept, and the young pigs which are not wanted for stores for the next winter sold off as soon as they are able to leave the mother. Let us see what buildings will be required for this purpose. There should be two or three styes under one roof, either of wood or brick, each of them 7 by 6 feet, and 4 feet high to the wall-plate; a good-sized pound, 7 by 12 or 14 feet in length should be attached to each. The fence of the pound should not be made of brick but of slabs of wood placed sufficiently near together to prevent the little pigs creeping between them; the building should face the south, and the bed should be raised 6 inches above the pound, and slope gradually towards it. Close at hand should be a cistern for wash, sufficiently large to hold at least a truckload of grains of 150 bushels, as it will sometimes happen that it will be necessary to keep the young pigs on hand longer than is recommended, or, it may be desired to feed them off as porkers.

As to the sort of pig which is most profitable, I incline after several experiments to a half-bred Berks. High-bred pigs, though they feed on less than others, are apt to be delicate in constitution, and are not such good or prolific mothers as the half-bred sorts. What a poor man wants is a sow which will bring on the average ten pigs at a litter, and this twice in the year, and bring them up herself in good condition without the assistance of the cow; and as far as I have been able to see, a half-bred Berks will answer this description better than any other. In some parts there is a prejudice in favour of white pigs. Wherever this is the case a half-bred Yorkshire may be preferred; but the point I wish to insist on is, that a high-bred pig is not a poor man's pig, unless he can buy one at six or eight months old as a store—in that case it will answer his purpose better than any other, especially if he likes his bacon fat, with a very slight admixture of lean. It is astonishing what a large bury of manure may be produced by a small number of pigs, if only care be taken to put by everything for the pound. Potato-haulm when dry, weeds of every kind, dead leaves, or grass, fern, or heather where it can be had—all should be carefully collected, and, after being well trodden by the pigs, moved to the heap, and in due course passed on to the ground. There is no doubt about the profit of this part of pig-keeping, though some authorities have questioned whether a pig is ever fed by a cottager to a profit; but to say nothing of other considerations, I am of opinion that this may be done. If all money paid out of pocket for the purchase of the pig, for grains, flour, and food of every kind is calculated, I think a pig may be fed for 8s. a-score; and this, when the pig is killed and salted, will give a cottager his bacon at less than 6d. per pound—no slight advantage, be it remembered, when he cannot buy butchers' meat under 8d., and when it is also remembered that one pound of bacon will go as far as two of fresh meat. Then there are all the incidentals to be taken into account—the pig's company, the refuse he consumes which would otherwise be wasted, the manure he makes, last and not least the air of comfort and contentment which he gives to the cottage when he is suspended from the ceiling in the shape of flitches. When all these points are duly weighed, I think I shall not be far off right in saying that every cottager ought to feed a pig, or two if he can, for pigs are sociable animals and thrive best in company; and if two are not required for the use of the family, one of them can be readily sold.

Next to the pig comes poultry, another very useful adjunct to the kind of farm we are describing. At some seasons they will require to be kept away from the fruit trees, but it is astonishing how soon they learn what they may do, and how far they are permitted to go. With regard to their dwelling-place, if the pigstye is ceiled with boards about 4 feet from the ground, the vacant space above will make a very good roosting-place, and the warmth from the lower storey will make the hens begin to lay earlier than they otherwise would.

Here again, as with pigs, I believe the most profitable sorts will be found to be half-bred. The cross between the Dorking and the Cochin, or the Dorking and the Brahma will be ready for the table at three months old, and as they will begin to lay in January, and the chickens are remarkably hardy, there will be two or three hatches ready to send to market at the end of May or beginning of June, when they ought to be worth 6s. a-couple. If these half-breds are allowed to grow to their full size they will weigh 7 or 8 lbs. each. But the best cross for the table I have ever meet with is between these half-bred hens and a Game cock; so much so, that I should recommend it for that purpose in preference to any other cross, or even to pure-bred birds, for the pure Cochin is an ugly bird for the table, and is also too fond of sitting. The Brahma is much the same in

these respects, the Dorking is too tender in constitution, the Game requires a large run, and does not do well in confinement; but if instead of chickens for the table, eggs are required for sale, the Hamburgh, Spanish, or Houdan will be found the most profitable breeds.

But is there any profit in keeping poultry? From my own experience I can say that there is; not a large one, but still a fair profit after paying all expenses of food, and charging the chickens throughout the year at 4*s*. a-couple, and the eggs at fourteen for 1*s*.

Ducks are a more questionable kind of stock for profit; they ought to be sold off when young at 9*d*. or 1*s*. each. They will then pay well to the grower; but if he keeps them on and feeds them for the table the profit will soon disappear, for a batch of young ducklings will eat as much as a pig. Nor should I recommend either Turkeys or Geese, unless there are special facilities for keeping them.

There is one kind of stock for a fruit farm which I have not yet mentioned, because I have no fancy for it myself and have never tried it. I mean a hive of bees. They cost nothing to feed, for like Pigeons they live upon your neighbours, and bring their produce home; but I expect that bee-keeping is a *specialité* which is only to be attempted where there is a mutual attraction, and this does not always exist; for bees, I am told, have their likes and dislikes to particular persons just as their betters have. There is generally a good demand for honey, and if this should not be the case it is an article which may be profitably consumed at home, and will be very popular wherever there are children. I have heard that in a good year the profit on a hive of bees is reckoned to be as high as 15*s*. or £1.

I am conscious that one serious objection may be raised against what has been hitherto said in these papers: "You have gone in entirely for what is profitable, and neglected the beautiful, unmindful of the French dictum 'that the beautiful is often quite as useful as the profitable, and sometimes more so,'" and as I fully acknowledge the truth of these last words, I will make what amends I can, mindful of the old adage:—

"Omne tulit punctum qui miscuit utile dulci."

I will go so far as to say that the fruit farm will not be perfect unless it is enlivened by flowers, among which their queen, the Rose, should hold a prominent place. The gable wall of the cottage will probably be covered by an Apricot tree, which in good seasons will furnish no inconsiderable item towards the rent, but the front and other parts may well be given up to climbing Roses, such as Maréchal Niel with his golden blossoms, which he will give forth in abundance against a wall, however coy he may be of displaying them unless provided with this protection, and the Gloire de Dijon, the most prolific of all Roses. But in speaking of the Rose, I have a shrewd suspicion that by growing it the fruit-farmer may unite the *utile dulci* very much to his own advantage, and may turn it into a profitable crop. I once gave a basket of Roses to a Manchester salesman as a present to his wife, and the next time he paid a visit to my farm he confided to my man the fact, that his wife, being of a practical turn of mind, sold my Roses to a lady for the sum of 7*s*. 6*d*. I have also discovered that another who sometimes visits the black country, and comes before he starts to beg a Rose for his button-hole, generally selecting a full-blown specimen, has an eye to business as well as to personal adornment, for he never brings the Rose back with him, as he can sell it readily to some of his customers for 6*d*. These facts lead me to imagine that the fruit-farmer may do worse than put in a few dozen Briars to be budded with Roses; and if he has a road or path through his plantation, he may make it much more "eyeable," as they say in these parts, by erecting some rough rustic arches across it with oak poles, and covering them with the Gloire de Dijon Rose. In addition to the Gloire, which will seldom be without a blossom from the middle of June till the frosts set in, he should grow as standards Sénateur Vaisse for a dark Rose, and John Hopper for a pink Rose. I mention these varieties as being good croppers and having compact blossoms, which will bear the transit well; and if the fruit-farmer will follow my directions, I think he will find that a pot of Roses will not be the least profitable or the least appreciated produce which he can send to the markets of the great smoky towns of the north.

I hope that I have carried my readers so far with me as to convince them that a working man may make a very good living from a small fruit farm, planted and managed as I have described. If a man has a small freehold of his own in a suitable situation, I do not think he can turn it to better account (to say nothing of the pleasure and interest derived from this kind of cultivation), than by planting it with fruit; or if a man has laid by sufficient capital, say £100 or more, I do not think that he can make a better investment of it than by taking a lease of four or five acres of suitable land for fourteen or twenty-one years, and planting it with fruit at his own expense. But my principal object in writing my experiences on this subject is the hope that they may induce large landowners to take the matter into their consideration, and establish a few such farms on their properties as inducements to thrift and industry, and as steps in the ladder to enable the deserving labourer to rise in his own profession in life. In this case the landlord should plant, at any rate, a portion of the ground with the best varieties of fruit, and those most suitable to the district, leaving the tenant to fill up the rest in time with grafts or cuttings taken on the spot. The rent for the first two or three years should not be above the agricultural value of the land, but it may be raised as the fruit trees come into bearing, till on a good soil it reaches £5 per acre or more. In such a case, where the landlord is at the expense of planting, I do not think that a lease should be given, as if the trees are neglected the occupier should have immediate notice to quit. The land selected should be of a fair quality, suitable for the growth of fruit, and within reach of a good market, or of a railway station, to which the produce may be sent. If these conditions are observed, I think a few such farms held out as rewards to deserving labourers would help to raise the tone of the whole district, and be a benefit to the community at large. I have a strong feeling that in the present day we want every means that can be devised to promote the growth of that self-reliant independent spirit which is the cause of a country's greatness, and to arrest the spread of pauperism. This last evil must be cut-at at both ends if the quality of a population is to be maintained—at the lower end by checking the indiscriminate system of out-door relief, which is simply a premium on improvidence; and at the higher end by offering every aid to thrift and industry, and every inducement to hardiness and independence, for wherever these qualities are dying out among the bulk of a people, that country, whatever its wealth may be, is not far from a fall. I believe that the establishment of such farms as I have described would have some influence for good, and if these papers should have the effect of inducing anyone who has it in his power to make the experiment, their purpose will have been sufficiently answered.

GOOD PEAS.

I use Ringleader, Little Gem, Advancer, and end with Veitch's Perfection. The three sorts first named do not require sticks; the last requires a stick here and there. I do not like Peas that require sticks. The birds make more havoc with staked Peas than with those unstaked. Moreover, you can net unsticked Peas better than sticked ones.

A dish of King of the Marrows was sent to me by our clergyman; they were large and of admirable flavour. I believe the stems grow 5 or 6 feet in height.

If Peas are not sticked or netted, the birds can only make havoc on the exposed side.—W. F. Radclyffe.

REMONTANT HYBRID ROSES.

De Perquet's French dictionary is by no means a first-rate authority to consult for terms not in frequent use in ordinary conversation. Being a compilation made in and for the preceding generation, it is at the present time an imperfect one also. Remontant is a French word with every probability of becoming an English one too. It is purely and simply the present participle, answering to the English participle in *ing* of "remonter," which in Spiers' dictionary, now the standard work for literary and other reference, is given with some twenty different shades of meaning, besides idiomatic phrases in which it is used; its general meaning is to re-ascend, to rise, or ascend again. "Hybride" will also be found twice in the same complete work, first as adjective, hybrid; second, noun mas. or fem., also hybrid. Peduncle is a botanical term in frequent use, explained by Dr. Lindley ("School Botany," p. 11) thus, "The stalk of the flower is its peduncle, and if the latter is divided into many smaller stalks its divisions are called pedicels," sometimes written pedicles. One of the greatest of living scholars, Archbishop Trench, deprecates strongly the

insertion of purely technical terms in the dictionaries of common use—a principle adhered to in the main by the best compilers. It is not profitable, therefore, to be searching for words where they are not to be found, especially in what the Archbishop terms "that absurdest of all books, a pronouncing dictionary," whether of Walker or of anyone else.—A. H. Kent.

BELTON GRAPE ROOM.

[The following is the report on the system of keeping Grapes pursued by Mr. Moore at Belton, referred to at page 51].

The Grapes were cut on November 9th, 1871, and the stems put into bottles of rain water with a little charcoal in each bottle. Soda-water bottles were used, and filled a little more than half full of water; when placed in the rack the water stood

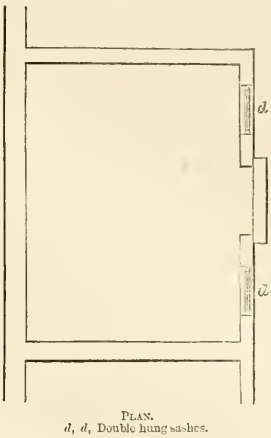
at an angle, which it was thought would prevent its evaporation. Two bunches were weighed when placed in the room, and were ticketed 2 lbs. and 1½ lb. respectively, in order to test if



Plan.
d, *d*, Double hung sashes.

the berries had the power of taking up the water in the absence of leaves. On December 21st these bunches were again weighed; the 2-lb. bunch was found to have taken up 1 oz., and the smaller one three-quarters of an ounce. The room was kept cool with closed shutters in consequence of the changeable but for the most part severe weather, the heating power being only used to keep out frost. In this way a very steady temperature of about 38° was maintained in the room, and only on two occasions did it fall below that point—namely, on the 19th of November, when the thermometer stood at 37°, and on the 8th of December, when it fell to 36°. The temperature never rose above 43° at any time. The Grapes appeared to be keeping perfectly up to December 19th, when a few mouldy berries were observed and cut out; on the 20th they were again closely examined, when it was found that many of the berries were cracked; these were at once taken out. The 21st being a drier day the windows and door were opened, and the heat turned

on; at this time a large number of the berries had burst; the stems were then drawn out of the water, with the view of checking the bursting of the berries. On the 22nd and 23rd, the weather being very wet, the room was kept closed except the top ventilator; still more berries kept cracking. The 24th being a dry day the room was again fully opened; the berries were rapidly bursting. On the 26th and 27th 115 lbs. of berries had to be cut out, and the stems were inserted into Mangold Wurtzel, and all the best bunches removed into the vinery. The remainder were inserted in Mangolds and kept in the room. On the 28th 4½ lbs. of berries had to be cut out. On the 29th and 30th the cracking was to a great extent checked, as on those two days sixty-three berries only had to be taken out, and these chiefly in the room.

The above remarks apply to the Black Alicante Grape. The Muscat of Alexandria did not crack, but the berries discoloured, commencing at the footstalks.

The Grapes when cut in November were all perfectly ripe and highly coloured.

It is desired to know what is the true cause of the failure. The accompanying are a plan and section of the Grape room. —W. Moore.

NOTES AND GLEANINGS.

Mr. Martin Sutton, the head of the well-known firm of Sutton & Sons, Reading, to whom was lately granted the special warrant of seedsmen to H.R.H. the Prince of Wales, invited the numerous hands employed in the warehouses and offices to his residence, Cintra Lodge, where the convalescence of the Prince was celebrated by a display of fireworks and illuminations. A military band was in attendance, and refreshments were provided, of which about 300 partook.

—— Gardeners' Royal Benevolent Institution.—The Rev. S. Reynolds Hole is to preside at the next anniversary dinner.

—— Mr. John Andrew Henderson died on the 13th inst. at Hamilton Terrace, St. John's Wood, aged 77. Such is the brief announcement we have to make of the departure of one whose name in former years so intimately associated with the Pine Apple Place Nursery, from the management of which, however, he had for many years retired.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The time is at hand for beginning operations here in earnest. One of the first steps is to plan out every inch of ground for the whole year, and to put laths, descriptive of the manuring, the kind of crop, and what it is to be succeeded by, at the heads of the quarters. It is also necessary, in order to follow up a systematic rotation of crops, to keep a cropping-book corresponding with the labels. Most people will be laying in their stock of seed for the year. A little *Cauliflower* and a pinch of *Brown Cos Lettuce* should be sown in boxes placed in a forcing house. Slopes should be forthwith formed, about 3 feet 6 inches wide, running east and west, and attached, if possible, to the framing ground, as such crops as *Horn Carrots*, *Early Lettuces*, and *Radishes* will require occasional covering with litter. Slopes of this kind, after having borne their spring and early summer crops, will be free for autumn ones, as *Endive* and autumn *Carrots*, or for raising a stock of winter Lettuces. The sooner *Asparagus* beds are manured and earthed the better. Plant *Jerusalem Artichokes*, *Horseradish*, and *Sea-kale* as soon as possible. Plant a few early *Potatoes* 8 inches deep, and draw off 2 or 3 inches of soil in the first week of April as a cleaning process. Sow *Parsley*, early dwarf *Cabbage*, Round *Spinach*, and Early Dutch *Turnips* on a warm slope. Select some small *Onions* of last year's growth, plant them a few inches apart on the surface of the soil, and cover them with earth; many of these can be drawn early in a green state, whilst others can run on for early kitchen use. The true Two-bladed Onion is the only one fit for this purpose, as it does not run to seed, but the very smallest should be selected for this purpose. Now a small patch of this kind, for producing young Onions early, should be sown in a warm corner very thickly, and protected as directed for Radishes. A well-prepared situation should be chosen for *Shallots*, over which some charred refuse should be thrown, and the bulbs placed on the surface.

FRUIT GARDEN.

The thinning and pruning of orchard trees should be proceeded with, and liberal dressings of manure given to exhausted soils. Prune and remove the suckers from Filberts, which rarely, except in Kent, get the management they require. Recently-planted orchard trees should be securely fixed, by using a little hay or moss at the tie to preserve the bark. Fruit-tree borders, particularly for the finer kinds against walls, should be made with fresh, turfy loam; so let that be prepared. Where the loam is heavy add road scrapings for the Peach and Apricot, but for Cherries and Plums use loam itself. Pears require a small quantity of cow dung, but not if the loam is rich. Dust over on damp mornings, with soot and lime, Gooseberries and plants which are attacked by birds, for preserving the buds of which two or three dressings will be sufficient. Raspberries may have the old wood removed and the new shoots thinned, the shortening of them being deferred until another time.

FLOWER GARDEN.

Wherever there is a large extent of mixed shrubbery some care is necessary to prevent the stronger-growing bushes from overgrowing the weaker ones, and it will be found better every few years to lift and replant the former than to prune them severely, as this, by inducing the growth of luxuriant wood, prevents the habit of blooming profusely. Never allow a margin of bare earth to intervene between the grass and the plants, but cover it with such low-growing plants as Periwinkles. The pruning of the more common kinds of Roses may now be done. Should, however, a part of the Provence, Moss, and others of the summer-flowering kinds be required to bloom late, reserve a portion till April for that purpose. The produce of Auricula seed sown last autumn will now need attention. If they have been planted out in sheltered beds it will be advisable to stir the soil with a blunt stick, remove the dead leaves, and to clean the beds thoroughly, after which a top-dressing of a compost of decayed horse manure and leaf soil should be applied to the depth of half an inch. It will be necessary to begin the destruction of snails by setting baits, such as bran, &c., to decoy them. Flowering plants in pots must be very carefully attended to, according to the directions lately given. Phosphoric poison will be found an effectual means of destroying mice. Polyanthus seed may now be sown in pots. Many of the Tulips are now so forward that, unless protected in some way, serious consequences may result to the embryo blooms. I would advise that some sandy peat be put in small cones over the rising plants just as they emerge from the ground, which will greatly protect them; this would, however, be detrimental if it were deferred until they opened. Pinks and Pansies will still require protection as previously recommended, but Carnations and Picotees in frames must have all the exposure possible. Ranunculus beds may be thrown up in ridges of about 4 inches, so that the lower part of the bed is allowed to remain undisturbed. By this means advantage can be taken of a fine day, about the 14th of February, to rake them level, as when suffered to lie in the ridged state the surface soil becomes sooner dry.

GREENHOUSE AND CONSERVATORY.

Some of the conservatory climbers, as those on pot trellises, will soon want dressing. The time for doing this must, however, depend in some degree on the time at which they are required to blossom. Cinerarias which are cramped in their pots should have a shift, as should also Chinese Primroses for spring work. Frequently examine Heaths and other plants which suffer from damp at this season. It is often necessary to keep a little air on at night, when a slight fire should be maintained, which, with sulphur efficiently applied, will greatly help to keep plants free from disease. Shift all greenhouse plants frequently to prevent their growing one-sided, and see that no decayed leaves are allowed to remain on them. Keep up a succession of blooming plants from the forcing pit in the conservatory, and do not let the temperature fall below 40°. The larger kinds of Fern and some dwarf Palms have often a good effect when skilfully introduced among mere forced flowers.

STOVE.

Potting may be proceeded with from this time onward, but it is not necessary that this should be the case with Orchids, except to facilitate the dispatch of spring business. Extirpate insects when you have any leisure. The snails may be baited for by laying a slice of fresh-cut Turnip on the spot, examining it about nine o'clock in the evening and again the following morning. The Blatta or cockroach may be destroyed by spermaceti and arsenic, say 2 ozs. of the former to 1 oz. or less of the arsenic. This may be done by dipping sticks in the composition and pushing them into the pots. Woodlice may be caught in a variety of ways; they will resort to a corner that is kept dry, and may there be scalded. Thumb-pots with dry paper, hay, or rags will entrap them.

FORCING PIT.

Introduce into the forcing pit bulbs, Roses, Pinks, Lilacs, and plants of a similar description for succession. Take care that the roots of plants in plunged pots are not burned; no portion of the plunging material in the vicinity of the roots should exceed 75°. Maintain an average atmospheric temperature of 60° at night and 70° by day, admitting air on all favourable occasions.—W. Keane.

DOINGS OF THE LAST WEEK.

Gathering vegetables, trenching, and digging were our only occupations of importance during the last week, as no very delicate operations could be proceeded with on account of the damp condition of the soil.

The Incomparable White Celery is still looking well, but it has suffered more from the long-continued wet weather than the Red, which stands out clean and fresh, whilst the other shows signs of damping and decay at the points. Notwithstanding the advantages of the bed system in economising space, I think in such unfavourable weather the plants are safer in single rows.

Our beds of Sea-kale, each of which has two rows, we covered to the depth of 6 inches with ashes, placing some hot leaves in the trenches between the beds, and also upon the top of the ashes. When treated in this way the heads generally come stronger than when the plants are taken up and placed in a Mushroom house.

Prepare for planting Asparagus, Sea-kale, Rhubarb, and Artichokes, and turn over the ground intended for Carrots, Onions, and Potatoes. Made mild hotbeds for Carrots, Radishes, and Potatoes, and placed many of the earliest of the last-named in shallow wooden boxes. In this position they make a very free growth, but if early-ripe tubers are desired they are produced better in 60-sized pots.

FRUIT GARDEN.

Kept the fruit-room well aired by means of fire heat and ventilation during the early part of the day. On foggy days keep the ventilators shut and give a little air at the top; on sunny days do not give much heat for fear of making the air too dry, and thus causing the late Grapes to shrivel. Strawberries should be brought on very gradually, and watered very carefully. Inexperienced persons should not use saucers for early crops unless they take care to see that these are empty shortly after watering.

Fruit trees intended to bear in pots may be raised, replunged, and mulched or surfaced with rich compost. It is too late to repot should fruit be wanted at all early, under ordinary treatment; that is best done at the end of summer, in order that the pots may become full of roots before the tops break into growth. Good results may notwithstanding be obtained by potting now and placing the pots in a mild bottom heat, whilst the head is kept as cool as possible until the fresh roots are near to the sides of the pot. To have ripe Strawberries in March, the plants must be well established by the middle of September. Plants taken up even now would make little progress if put in a forcing house, however gradual the increase of temperature. Those lifted in March and April and placed where there is heat will do very fairly, particularly if bottom heat sufficient to encourage the roots a little more than the top, can be given them at first.

Preparations for the planting of fruit trees may still be proceeded with.

All hardy fruit is scarce. In a good fruit season Apples and Pears would not bring much until after midwinter, but this season half a peck of Apples has often brought more money than a couple of bushels did in more plentiful years.

ORNAMENTAL DEPARTMENT.

Box-edgings may now be cut, but the best time for doing this is in spring, when the frost is nearly gone, or early in autumn. If cut in winter or too early in spring they are apt to have, for a time, a stubby half-dead appearance, instead of the rich fresh green.

Transplanting.—Trees from 4 to 7 inches in diameter of bole may be moved advantageously, even without preparation, by tracing the roots and by means of a timber gig. This consists of two wheels, an axle between them, and a pole, to which horse-power is applied in proportion to the weight. We would rather have done the work early in November, as when the soil is too wet it is difficult to pack the fine saved fibres properly, and on this packing much of the success depends.

Hyacinths and *Tulips* peeping up out of doors would be safer if little cones of ashes, rough cinders, sand, or, best of all, fine charcoal, were placed over them as a protection from frost and excess of moisture. A little litter would be an equally good protective against frost, but unless carefully removed in mild weather, the damp which accumulates about the top of the plants will injure them. It is not even advisable to use a shading or protecting cloth to the finer kinds too early, as the flower-stems are thus apt to become drawn and weak. When the bulbs are planted regularly over a bed, each forward bulb, as it pushes through, may be protected by an inverted 4-inch pot, the hole of which is stopped. Many years ago we used to protect Tulips, Hyacinths, and the earlier Narcissus of the good sorts in this way, adding mats or litter in severe weather, and taking off the pots in bright warm weather.

Heartsease, Pinks, and *Carnations,* especially if young plants out of doors, will require to be examined and fixed firmly in their places after such changeable weather. In fixing them with the fingers, a little dry sandy soil with some small charcoal will be of advantage, and will prevent future frosts throwing the roots bare.

Auriculas can scarcely have too much air in this mild weather, but the sash over them must be tilted back and front to prevent deluges of rain from inundating the pit or frame.

Shrubby Calceolarias.—The first cuttings inserted in the cold pit at the end of October are now matted with roots, but those inserted in November are merely beginning to strike. We would have liked better if the earlier had been like the later, as we must do everything to keep the more forward back until the weather will permit us to plant them out more thinly. Though they stand damp well, we do not want them to be wetted by the heavy rains, and therefore take the sashes off only when there is no prospect of rain, merely tilting the sashes on wet drizzling days. Without being in fire heat or in pots, it is rarely that our bedding Calceolarias are ever troubled with the nibble of an insect.

Chrysanthemums.—We have now only a few of these flowers left. The tops should be cut down, and the plants turned into the soil to set the pots at liberty. By-and-by cuttings, suckers, or bits of the old plants may be grown on for next season's blooming. For beds out of doors, or for walls, large masses of this plant are more suitable. For flowering in pots, cuttings and rooted suckers have their special advocates. We never saw much difference in the results, if equal attention was given to potting, and especially watering. We used, after the plants were fairly started, to turn them out into rich soil in May and June, and pot them with balls at the end of October. These and the winter-flowering Salvias do well under this treatment, and much watering which would be necessary for pots in summer is saved. We used to pack four or five plants in a vase, as closely as possible, leaving an open space in the centre, on which the bottom of an 8 or 12-inch pot was placed. The shoots of the side plants hid the central pot, and a fine pyramid of flowers was obtained. To save frequent watering, these plants were in summer plunged in a bed of half-decayed leaves, and the pots were moved frequently to prevent the roots going much beyond the pot.

Camellias.—If the soil is well drained, plants swelling and opening their buds should be rather freely supplied with water at least as warm as the temperature of the house. Weak liquid manure will also be acceptable, and especially if instead of being of a hot it is of a rather cool nature, as that made from cow dung which has been dried somewhat, and is at least a twelvemonth old before it is added to the water. If good guano is used, 1 oz. to the gallon is enough. It is well to remind those who wish to have Camellia blooms early in winter, that it is not advisable to apply any extra heat for that purpose then; but whatever extra heat or forcing is given should be applied so as to excite early growth in spring, and the early setting of the bloom-buds in summer. When these conditions are secured, the buds will swell in autumn and open at the beginning of winter in a moderate temperature, such as 45° at night. A high temperature applied to make the buds swell and open will often cause them to fall. The true time to force is when there has been a rest of a few weeks after blooming.

Deutzia gracilis, with its spray of white flowers, is very useful at this season for relieving flowers more brilliant in colour. Very little heat soon brings it into bloom. I have flowered it well along with Lilacs, Rhododendrons, &c., by lifting the plants with balls, potting them, and plunging in a slight hotbed six weeks before any increase of the atmospheric temperature was given.

Bulbs.—Hyacinths, Tulips, &c., may be flowered early if the bulbs are potted early in autumn. No forcing can well take place until the pots are full of roots. When I have had my supply of bulbs late in the season and wanted some in flower by Christmas or the New Year, I have plunged the pots in a mild hotbed out of doors, and put little over the bulbs, the object being to have the pots well filled with roots before the tops moved. The heat beneath is of no use except under such circumstances and for early bloom. In taking the bulbs to a hotbed after plenty of roots have been made, it is desirable to shade the yellowish growth above the soil either by an inverted pot, which helps also to draw-up the flower-stem, or by a thick mat over the glass, especially in sunshine, until the top growth acquires its natural green colour. When the flower-stems are rising strongly they will often begin to open their blooms sooner if placed on a shelf nearer the glass, but otherwise in the same temperature. Before the plants are taken to a room, window, or cool house, the pots should be moved out of the hotbed, and then the plants be gradually hardened off, so that the change of climate may not be felt.

Once I had to keep up a succession of Hyacinths in flower with a limited number of glasses, the same glasses having to be supplied with bulbs in bloom as long as they could be had. I grew the whole in pots, turning the plant into the glass when a few of the lower flowers on the spike had expanded. The ball was turned out of the pot, and the whole of the soil washed away in a pail of water at from 65° to 70° without injuring a root. The roots were then put carefully into the glass, sup-

plied with soft water, and, if the glass was coloured, some charcoal and pieces of manure were added.—R. F.

TRADE CATALOGUES RECEIVED.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Character (*W. Taylor*).—It is a satisfactory testimonial; and on what ground you could have thought it needful to consult a lawyer we cannot discern.

Setting Boilers—Raising Flow-pipes—Evaporating Tanks (*M.*).—In fixing a saddle boiler two plans may be adopted according to the size of the boiler. If the boiler is small raise it at the sides the thickness of a firebrick or tile above the furnace-bars; leave an open space of 6 inches at the farther end; build with brick a flue 6 inches wide round the sides of the boiler, and bring it as near the furnace doors as you can. This flue may be made of bricks laid across from the curve of the boiler, or by an iron plate so placed. The opening at each side near the furnace door allows the heat and smoke to go round the outside of the boiler, then to pass along the top and up the chimney, the farther end being blocked up. In a large boiler we should prefer having two flues at the sides by using two iron plates as dividers on each side. The heat would then pass round the lower part of the side of the boiler, return near the upper part of the side, and thence go along the top up the chimney. Iron plates 7 or 8 inches wide are very good for this purpose. Soot-doors must be provided for all these flues. Like the writer at page 15, we have made water circulate in all modes, even to going downhill; but it is much better that the pipe should rise from the boiler, and then go and return on a level until it dips down to the bottom of the boiler. It is still better, in our opinion, when there is a slight rise to the farther end, with an open air-pipe there, and then a similar decline to the bottom of the boiler; and we say this after having been under the necessity of working many plans. The most interesting part of the article at page 15 is that relative to the importance of having hot-water pipes on a level, and having as few returns as possible. Not long since we heated a small house by taking round three pipes on a level beneath a stage, so as to leave a pathway free in front and at back. The boiler was placed at the north-west corner. There was one flow and one return. When the flow arrived at its right position it was joined to the usual manner to three pipes, and these went round the west end, the south side, the east end, and the north side to no great distance from the boiler. In that space the rise all round would be about 3 inches. At the highest point, just where the three pipes were changed into the one to return again to the boiler, an open air-pipe was inserted. With the exception of this short piece visible that joined the return, all the pipes were flow-pipes, and nothing could answer better; the chief advantage being the uniform heat in the pipes all through. The steam or evaporating-pipe alluded to, page 15, we think you will understand better if you suppose that the flat iron pipe is merely an open level tank, and the 2½-inch pipe that goes through it from end to end is intended to heat the water in the pipe or tank. All that is necessary is to connect that 2½-inch pipe in the tank with the flow-pipe near the boiler, and with the return-pipe at the other end. The circulation will then be as complete in that pipe in the trough as anywhere else.

Flower Beds (*An Amateur*).—Both your plans No. 1 and No. 2 would look well if suitably planted. No. 1 is the more proportional of the two, but the ends of your square figures should be curved-in to correspond with the curve of the circles. Notwithstanding this, we much prefer No. 2, and chiefly because it breaks in on the stiff monotony of the outline. In No. 1 you have a 4-feet walk all round, and a band of turf between the walk and the beds. In No. 2 this regularity is broken in upon. The grass all round is wider, and round the centre, especially, the width is unequal or diversified, which of itself will be a great advantage. The fault of No. 2 is the want of balance in the size of the beds, and the narrowness of the turf between the beds at places. We would have none less than 4 feet. We would alter it thus: Reduce your centre circle to 6 feet in diameter, and add a foot to the grass and a foot in width to the four beds round it. Reduce your four circles from 6 to 5 feet in diameter. We do not agree with you as to substituting an oval for the two end figures. We do not think you can better the outline, but we would lessen the size by placing the two curved inside lines from 2 to 3 feet nearer the boundary. Pencil a group as thus suggested, and you will see you will have more room for turf, and the beds will be better balanced.

Geranium (*D. F. J. K.*).—We cannot attempt to name the varieties of florists' flowers.

Waste Lands (*A Constant Reader*).—We know of no work on their cultivation exclusively. Arthur Young's "Agricultural Surveys" of various counties give information on the subject.

Garden Architecture—Emigration (*A Novice*).—We think "Garden Plans" and "Greenhouses for the Many," both published at our office, would supply the information. We are told by a good authority that Victoria in Australia is the best new home for gardeners.

Planting a Span-roofed House (*A Market Gardener*).—We would advise planting both sides of your span-roofed house with Vines 4 feet apart, as thus you would have the house furnished sooner, even if afterwards you took the Vines across so as to fill both sides of the roof. We would in general only take one stem to a Vine instead of two, but if one became very strong you could give it more room. Planting at 4 feet apart, the stems on crossing would thus ultimately be 2 feet apart; at that distance a great weight of Grapes can be cut, but you can expect nothing to grow under the Vines. The Vines you name are good late sorts. We are not so sure of Mrs. Pince and Madresfield Court hanging so long. We have no doubt you will succeed very well with the trees as bushes in the orchard house, if the roots be curtailed at times; but after trying such modes largely we think that for economy and profit we would plant the trees on each side, and train them on a slope 18 inches from the glass. Vines may be grown 7 feet apart; but even then the shade will injure the colour of the Peaches.

Celery Lifting (*A Lady in Cheshire*).—It is not a good plan to lift Celery and store it in a potting shed, for it parts with a considerable amount of moisture, and on that account loses crispness and flavour. It ought to be left in the ground, and protected with litter in severe weather, but remove the covering when it is mild.

Pigeons' and Fowls' Dung (*Aspire*).—As both are powerful manures they should not be applied in such great quantity as stable or farmyard manure. A dressing just sufficient to cover the surface is enough, and should be pointed-in with a spade. We have given with advantage a dressing half an inch thick to Onion beds. Both are valuable manures for every description of vegetable crop.

Hotbed of Dung and Tan (*G. A. S.*).—We do not approve of mixing dung and tan together in forming hotbeds, not but that the mixture answers well enough for bottom heat, giving a steady heat, but the tan spoils the manure. We would, therefore, make a shell or lining of the stable manure, say 18 inches wide all round the bed, carrying it up to the required height, which at this season will be 6 feet at back, and 5 feet in front, and fill up the centre with fresh tan. The oily cotton waste you may mix advantageously with the manure in the proportion of one part to four of stable manure, and if you have sufficient to raise a bed 5 feet high at back, and 4 feet high in front, we should dispense with the tan.

Heading-back Maiden Apple, Pear, and Plum Trees (*Spero*).—We would not head back the trees more than 3 feet, as we presume you wish them to form pyramids or bushes, and this will give you shoots sufficiently near the ground. These side shoots should be encouraged, not stopping the lowest ones until they have grown a foot, nor the leader until it has made that length of shoot; then take out their points. If, from the top, strong shoots start besides the leading shoot, stop them at the third leaf; this will induce the lowest side shoots to push freely.

Cutting the Leading Shoots of Cupressus and Thuja—Peach Tree Gumming (*Amateur*).—You may cut off the leading shoots of Cupressus and Thuja without disfiguring them, and remove irregular growths. There are no shrubs that will bear pruning better than Thujas and Cupressus. We have some that are cut into close pyramids. We do not know what you can apply to the stem of a Peach tree badly gummed. There is no remedy. It is probably a consequence of the tree being on a foreign (Thum) stock. The belt of old Fir trees just outside the north corner of the garden cannot do any harm if the branches do not extend over the wall, or shade the ground. On account of the shelter they afford from north winds, we would not cut them down. If the branches extend over the wall and cause shade or drip, it may be desirable to lop, and perhaps cut down the trees. Remember that it is easier to cut down trees than to rear others that will afford the shelter of those removed.

Border for Climbers—Liquid Manure (*Black Edge*).—We highly approve of your taking up the concrete. We would make the width 2 feet, and if possible 3 feet, take out the soil, put in 9 inches of drainage, and then 2 or 3 feet of soil. The border would be far better than the boxes. A Myrtle trained to the wall would thrive if protected from frost in very severe winters. We would remove the offset at once, and place in the water two or three pieces of charcoal about the size of a nut. Bedroom slops are useful as a manure, if diluted with six times their bulk of water. They may be poured between the rows of growing crops of vegetables, or used in an undiluted state on ground before cropping.

Double White Violets, &c. (*H. Vincent*).—Write to some of the principal florists who advertise in our columns.

Treatment of Vines (*A. D.*).—Remove any loose bark from your Vines, and paint the stems with a mixture composed of 4 ozs. of sulphur, 2 ozs. of soft soap, and a small portion of soot, to half a gallon of water. The vinery started at the end of January should have a night temperature of 45° to begin with, gradually increasing it, so that by the time the shoots have grown an inch, 60° may be attained. Increase it in two weeks to 65°. In all cases allow a rise of 5° by day from artificial heat, and of 10° to 15° from sun heat. Syringe the Vines twice a-day until the buds break, when syringing should be discontinued.

Vines in Pots (*Essex*).—Your young Vines had the proper treatment until you say that in May, "they were much shaded by the permanent Vines." They would not be likely to form fruit-buds under such highly disadvantageous circumstances. The position to which you removed them, "the front stand of a plant house," was not good; they required more heat than they obtained there. We obtain fruiting canes of the strongest description from eyes inserted the same autumn, growing them on in a temperature of not less than from 60° to 65° at night after they are fairly started, but they must not be under shade. You should have shifted them into their fruiting pots by the end of July. As you have placed the Vine eyes on pieces of turf upon a Pine-bed, you will find full instructions how to proceed in No. 513, page 61, of last year's Journal of Horticulture. The Vines which did not show bunches try in both ways, but grow the largest portion from a single eye at the base of the cane. The fruit-buds must be formed and thoroughly matured before the leaves fall in autumn.

Peach House (*A. T.*).—Your trellis should be from 12 to 15 inches from the glass, instead of 6 inches. Have from 18 to 24 inches of good soil above the concrete. We prefer the saddle boiler and 3 or 4-inch pipes, but we like conical and tubular boilers very well, the simplest the best. A boiler with furnace fittings for such a long house would cost about £8, and two rows of pipes on each side would be necessary. Good 4-inch pipes will cost from 2s. 3d. to 2s. 6d. per yard, without the workmanship. Pipes may be purchased at any price; we lately heard of some put up very cheaply, but they proved to be poor rain-water pipes, dear at any price when used for hot water. We cannot recommend tradesmen. If particular, have a clear specification and a contract, and any of our advertisers will do the work well.

Conservatory (*Leamside*).—The best arrangement we can think of for such a house, 14 feet wide, would be a border all round, except opposite the plate-glass window, of 18 inches in width—wide enough for climbers—with a shelf or trellis-work all round of the same width, at about 3 feet from the ground, except opposite the window. That window we would take to the floor as a door, unless you can walk at once from the drawing-room into the central output of the conservatory. Then with a walk 2 feet 9 inches all round you will have a base for your central stage of 5½ feet. If you will be satisfied with a 30-inch path you will have a 6-feet base for your stage. Many would prefer a 3-feet pathway to give room to the ladies, even if thus they curtailed either

the side shelves or the central platform. This platform we would either have flat, 3½ feet from the ground, or, if a stage, have two or three shelves on each side, the slope facing east and west. There are three modes by which you can heat the house effectually. The pipes may be placed above ground under the side shelves, and if 6 inches from the climbers will not hurt them, and a thin board might be placed between the pipes and the stems of the climbers; but then we presume it would not do to have the pipes opposite the window, nor yet opposite the wide part in the centre. In this case the boiler could be placed at the north-west corner, pipes taken as far as the window on the west side, and right round as far as the wider part on the other. Three 4-inch pipes would be required. The neatest mode, if you can sink your boiler enough and do not mind a little more expense, would be to form a trench for your pathway, with a brick wall on each side, take three pipes all round in the trench, and cover the opening with galvanised-iron grating. In cold damp weather that grating will be very pleasant to the feet, especially if thin-soled boots are used. The third mode, and a very simple one, is to carry both your flow and return pipe from the boiler underneath the border and pathway, and then rise and commence at the north-west side, and take the pipes right round the house under the central platform, where they would be entirely out of the way. We would carry the pipes round either on a level, or, better still, with a rise of 2 or 3 inches, insert an air-pipe at the farther end, and make the connection at once with the return-pipe to the bottom of the boiler. To keep out frost, two pipes round under the platform would do. To keep plants in bloom in winter, or to force them, three 4-inch pipes would be better, placing them in such a position that all the heating would be in the centre of the house. We think the form of boiler is not of much consequence, and if you find the tubular so much to your satisfaction, we would advise you to have what suits you best. You will see other remarks on placing the heating pipes under the central stage. The pipes are thus quite out of the way.

GLAZING WITHOUT LAPS (*X. Y. Z.*).—Much less air finds its way into a house glazed without laps than into one with them. The danger lies in the glass being placed closely side by side, and no room being left in the groove, as in Mr. Peach's case, for the glass will suffer from expansion. We have no doubt that the zinc bars will answer, but as to their durability we will say nothing. Zinc roofs were recommended at one time because they would not oxidise or rust out, but they wear out, and are very sensitive to expansion and contraction by heat and cold. We would paint zinc bars if using them, but our experience does not enable us to speak decidedly.

SOWING THE BERRIES OF THORNS, HOLLIES, BAYS, AND BERBERIS DARWINII (*Dermod*).—It is not necessary to take off the pulp. They may be sown as they are, though it is usual to place the Thorn haws in a heap, cover them with soil for a twelvemonth, and then sow from the three-quarters to an inch deep. You may do this or sow, but the seedlings will not appear until the second year. The same remarks apply to the Holly and Bay, but in the case of the Berberis the pulp may be separated by washing, and the seeds sown in sandy soil in March. They should all be sown in the open ground early in March, choosing a warm sheltered spot for the Bay.

BEET FOR A RIBBON BORDER (*Trethowel*).—The best we have grown for this purpose is Dell's Crimson. Sow it in pans during the second week of April, and plant out the seedlings in the second or third week of May. We have sown it where it is to remain in the first week of May, thinning-out the plants to 8 or 9 inches apart, and they were as good as the transplanted seedlings. Amaranthus tricolor is not nearly so good as Beet, not so hardy, and altogether very different.

LATE PEAS (*Q. Q.*).—For producing a late supply of Peas, Ne Plus Ultra is excellent, and should be sown at the end of June; and Imperial Wonder is a good late sort, which should be sown at the same time. To fill-up the gap between Ringleader and Veitch's Perfection, Maclean's Princess Royal and Premier are excellent sorts.

ANNUALS FOR LATE FLOWERING (*Idem*).—They are very uncertain subjects for producing a late supply of flowers for cutting, but we find the large-flowered Emperor Stock and Phlox Drummondi exceedent for the purpose. The seed should be sown early in April in gentle heat. We have also had Asters in fine bloom early in October, from a sowing made at the end of April; Senecio elegans from seed sown at the same time in heat and the seedlings planted out; Sweet Alyssum and Candytuft, the latter sown early in June, and the former early in May. Calliopsis Burridgii flowers late, and so do Branching Larkspurs sown in April. Centranthus macrosiphon sown the last week in May, and Sweet Pea the second week in May, will flower until frost. The Tom Thumb varieties of Nasturtium are good sown the third week in April, and no doubt there are many others which do not occur to us at present. Crimson King Verbena is a satisfactory bedder, but would not do outside Purple King, which should either be raised or the positions reversed. Frogmore Late Pine Strawberry is superior to Elton, and is quite as late. For a late supply the situation should be open, but we do not think anything is gained by growing the plants on north borders. Cockscomb is an excellent Strawberry and would thrive with you.

CATERPILLARS IN LEAF MOULD (*W. Nock*).—The caterpillars are those of one of the many species of daddy-longlegs (Tipula sp.). They attack the roots of many plants.—I. O. W.

NAMES OF FRUITS (*D. F. J. K., Virginia*).—The two Pears are Chaumontel. They are now over-ripe, and becoming as usual bitter. Their shrivelling before ripening arises, probably, from their not having been well matured before they were gathered. (*Subscriber*).—It is not easy to name a Grape from seeing only three berries; still we venture to say that yours is Mrs. Pince.

POULTRY, BEE AND PIGEON CHRONICLE.

BLACK COCHIN-CHINAS.

I THINK your reporter has been a little severe generally on the Black Cochins exhibited at the late Bristol Poultry Show, and especially so on my unfortunate seven-months-old cockerel, which he designates a "miserable so-called Black Cochin." I shall not be sorry if it should give rise to a useful discussion on this breed, which I believe is destined to be very shortly as much in request as any of the other varieties of Cochins, if not more so. I can vouch for the purity of the birds shown by myself at Bristol, for I obtained the parents direct from Shanghai about two years ago, and I keep no other breed of fowls. If your reporter had been accustomed to see Cochins as they are found in China, he would be astonished at the difference which exists in the breed as we have it now exemplified in the Buff variety. The greatest improvement has taken place, and this, I think, will also be the case with the Blacks when more known. At any rate, I shall not be discouraged in my attempt towards such improvement.

It is generally supposed to be impossible to breed the Black Cochins true to feather; this is very likely to be the case if they are the result of the cross (referred to in the "Poultry Book" edited by Messrs. Wingfield and Johnson, page 13) between the White and Buff varieties, which produces, I believe, a Black, but which, after the first or second moult, shows white feathers; and this it was which induced me to obtain some birds direct from Shanghai, where I have friends, who selected and sent me my first birds.

I should like to say a few words about age, in the hope that judges will discourage as much as possible that which I fear exists to a great extent—viz., understating ages, or rather showing birds over a year old as cockerels and pullets. This I observe you have referred to in your remarks on the Dorking cockerel class at Bristol, and there is no doubt that this very unfair practice extensively prevails.—C. M. HOLE, *Tiverton*.

SILVER-SPANGLED HAMBURGHS.

HAVING attended several of the principal shows, and being to some extent a Hamburgh fancier, I was struck with the difference in what are now called Silver-spangled Hamburghs and those exhibited a few years ago. On reference to the second edition of the "Poultry Book," I find illustrated there a bold, well-shaped, white bird, evenly and distinctly spangled with black. On examining the prize pens at the Crystal Palace Show, I saw what I thought were black birds slightly pied with white, the white spots apparently running one into the other.

Mr. Beldon, in a letter published in an American paper, writing of Silver-spangled Hamburghs, states that they should be heavily and distinctly spangled; now, I maintain that the present breed of show birds are not distinctly spangled.—J. K. O.

WHAT A RAILWAY CAN DO.

WE so often hear complaints, and justly so, I think, of railway neglect in the conveyance of poultry to and from shows, that I think the following instance of celerity may, perhaps, be worthy of note. I had a pen of Golden Polands at the Durham Show, the Secretary of which was requested to forward the pen to the Edinburgh Show. All were to be at Edinburgh by Friday night, or at the very latest by Saturday morning at eight o'clock. Judge, then, of my chagrin to find my birds safe at home on Friday night, instead of just then being about arriving at Edinburgh. However, an hour or two afterwards, on consulting "Bradshaw," I found that if I sent a pen by mail train leaving Louth at eighteen minutes to 9, there was just a chance that they would get to Edinburgh by 8.5 in the morning; so I packed up a pen and despatched them, and as I could only prepay the carriage to Berwick, I placed a large card on the top of the hamper, requesting the railway officials not to remove the hamper from the train at Berwick, but to send them on to Edinburgh. They arrived, and won a prize; thus traversing a distance of fully four hundred miles in about eleven hours and a half.—G. W. B.

ANY OTHER VARIETY OF BANTAMS.

I AM sure Black Bantam breeders will say with me it is very hard that we cannot be treated like all other exhibitors. We pay the same entrance money, and have to meet in our Any variety class five or six different breeds—viz., Blacks, Whites, Gold-laced, Silver-laced, Japanese, Pekins, and of course it becomes purely a matter of taste with the Judges which shall have the prizes. How often do we see Pekins first, Laced second, and ifa third prize is given Blacks get it. We have few shows where Blacks have a class, and note when they have as a rule it is a good class numbering from ten to twenty pens. Of course, breeders of White and Laced Bantams may find the same fault. Now, what we want is either separate classes for all sorts, or dividing as follows: first, Blacks and Whites; second, Gold-laced and Silver-laced; third, Any other variety

of Bantams. I would ask all breeders who have to compete in the Any other variety class as it is at present, to give their opinion on the subject, and to bring the matter fairly before the committees with which they may come in contact. I hope some of our leading exhibitors in this class will take the matter up.—FAIR PLAY.

NORWICH POULTRY SHOW.

THIS Show was held on the 17th and 18th inst., in the Corn Hall, Norwich. The awards were as follows :—

GAME (Black-breasted and other Reds).—*Cock.*—1 and Cup, G. Sutton, Bootham. 2, W. Rayner, Ipswich. *hc*, S. Matthew, Stowmarket (2); F. Harding, Chingford; E. Aykroyd, Eccleshill; A. Haslam, Hyndley. *Hen.*—1, S. Matthew. 2, E. Aykroyd. *hc*, S. Matthew; A. Haslam; H. E. Martin, Smithorpe; E. Branford, Swaffham; T. Dyson, Halifax; G. Clements, Birmingham.

GAME (Any other variety).—*Cock.*—1 and 2, S. Matthew (Duckwing). *hc*, J. Jeken, Eltham (Duckwing). *Hen.*—1, S. Matthew (Duckwing). 2, E. Aykroyd. *hc*, S. Matthew (Duckwing); J. Jeken.

DORKINGS.—*Cock* —1, L. Patton, Hillmore, Taunton. 2, Henry Lingwood, Barking, Needham Market. *hc*, J. Smith, Shillingtee, Petworth; Capt. C. F. Bignold, Norwich. *Cock*—1 and Cup, Henry Lingwood. 2, Mrs. G. Clarke, Long Sutton. *hc*, Rev. E. Bartrum, Great Berkhampstead; T. Briden, Coneley; F. Parlett, Great Baddow; O. E. Cresswell, Early Wood, Bagshot; L. Patton.

COCHIN-CHINA (Cinnamon or Buff.—*Cock.*—1 and Cup, Lady Gwydyr, Ipswich. 2, R. Hawkesworth, Hanesworth. *hc*, E. E. Gray, Kensington Gardens, London; Henry Lingwood; J. Long, Plymouth. *Hen.*—1, C. M. Stuckings, Wye. 2, Lady Gwydyr. *hc*, Mrs. A. Vigor, Southfield, Uxbridge; E. Fearon, Whitehaven; S. R. Harris, Cusgarne; Henry Lingwood.

COCHIN-CHINA (Any other variety). — *Cock.*—1, Lady Gwydyr. 2, R. S. S. Woodgate, Pembury (White). *hc*, E Fearon; J. M. Otter, Newark (Partridge); F. Brewer Lostwithiel (White); R. S. S. Woodgate; Horace Lingwood, Crecting (9). *Hen.*—1, R. S. S. Woodgate (White). 2, Horace Lingwood. *hc*, E. Fearon; R. S. S. Woodgate (White); Horace Lingwood; Lady Gwydyr.

BRAHMA POOTRA (Dark)—*Cock.*—1 and Cup, T. F. Ansdell, St. Helens. 2, Horace Lingwood. *hc*, C. P. Hart, Eaton, Norwich; Horace Lingwood; Lady Gwydyr. *Hen.*—1, Lady Gwydyr. 2, Hon. Mrs. A. B. Hamilton. Woburn. *hc*, T. F. Ansdell; C. P. Hart; Dr. Holmes; F. L. Turner, Dorchester; Rev. J. D. Peake, Laleham; Horace Lingwood.

BRAHMA POOTRA (Light)—*Cock*—1, Mrs. A. Worthington, Burton-on-Trent. 2, H. Bowerbank, Pelsall. *hc*, Mrs. A. Worthington; F. B. Astley, Norwich; P. Haines, Diss; L. Peao, Chepstow; H. Mitchell. *Hen.*—1, J. R. Rodbard, Wrington, Bristol. 2, Mrs. A. Worthington. *hc*, Mrs. A. Worthington; J. Drake, Ongar; H. Dowsett; J. R. Rodbard.

HAMBURGHS (Gold or Silver-spangled).—1 and Cup, R. R. Parker, Ipswich. 2, W. Tiebner, Ipswich.

HAMBURGHS (Gold or Silver-pencilled).—1 and Cup, R. R. Parker, Ipswich. 2, W. Tiebner, Ipswich.

HAMBURGHS (Gold or Silver-spangled) —1, Ashton & Booth, Mottram. 2, J. B. Lakeman, Ipswich. *hc*, A. Wren, Lowestoft; W. Tickner; R. Wilkinson, Guilford; C. M. Stuckings, Ashford; N. Barter.

SPANISH.—1 and Cup, Mrs. Tonkin, Bristol. 2, J. Thresh, Bradford. *hc*, Col. J. Cockburn, Brackensdale, Norwich; Boulton & Gliddon, Bristol

ANY OTHER VARIETY.—*Cock.*—1, W. Dring, Faversham (Creve-Cœur). 2, J. Hinton, Warminster (Silver Poland). *hc*, Miss J. Cross, Brigg (Creve-Cœur); W. K. Patrick, West Winch (Poland); A. Cruttenden, Hawwards Heath (Gold-spangl d Polish); W. Tippler, Chelmsford. *Hen.*—1, Cup, and Commended, W. K. Patrick, Lynn (Polands). 2, F. Brewer (Houdan). *hc*, W. Dring (Houdan); C. H. Smith, Radcliffe-on-Trent (Creve-Cœur).

ANY VARIETY.—*Cockerel*—1 and Cup, J. Thresh (Black Spanish). 2, Lady Gwydyr. *hc*, C. Maggs, Melksham (Black Hamburghs); W. K. Clark, Tewkesbury (Silver Duns); J. L. Hanton (Silver Poland); Horace Lingwood (Partridge Cochin). *Pullet*—1, Lady Gwydyr. 2, H. Lingwood. *hc*, J. Thresh (Black Spanish)

BANTAMS (Game).—1 and Cup, W. Adams. 2 J. W. Morris, Rochdale. *hc*, H. P. Leech, Bury St. Edmunds; Hon. Mrs. Paget, Hoxne, Seole; J. M. Robinson, Sunderland; W. Adams, Ipswich; W. B. Africa, Ipswich (2).

BANTAMS (Any other variety).—1, Rev. F. Tearle, Gazeley Vicarage, Newmarket (White). 2, Mr. Lowdes, Stony Stratford (Pekin). *hc*, W. Neal, Clare; Page, Loughborough (Cuckoo); Hon. Mrs. Paget (Japanese); S. & R. Ashton, Mottram (Black); M. Leno (Laced).

SELLING CLASS.—1 and Cup, Lady Gwydyr (Cochin). 2, W. Boyes, Beverley (Game). 3, Hon. Mrs. Paget, Hoxne (Red Game). *hc*, A. Pace, jun., Milton, Lowestoft; E. Lantour, Ampthill (Dark Brahma); R. Loft, Woodmansey (Sultan); R. Brownlie, Kirkcaldy; Horace Lingwood (Partridge Cochin); W. Tippler (Houdan).

SELLING CLASS.—*Hens.*—1, H. Dowsett (Brahma) 2, Lady Gwydyr (Cochin). 3, R. Loft (Sultan). *hc*, L. Wren (Gold-spangled Hamburgh); B. Warner, Upton (Dark Brahma); J. Drake (Dark Brahma); H. Brown, Putney Heath; R. Postle, Gazeley (Black Red Game); J. B. Lakeman (Golden-pencilled); W. Rayner (Black Red Game).

SELLING CLASS.—*Cock or Cockerel.*—1, R. Loft (Sultan). 2, W. Boyes (Game). 3, Lady Gwydyr (Cochin). *hc*, W. Cutlack, jun., Littleport (Dark Brahma); Miss J. Cross (Creve-Cœur); W. K. Patrick (Poland); W. Dring (Creve-Cœur); H. Fisher (Gold-pencilled Hamburgh); R. Brownlie; Horace Lingwood; W. Rayner (Brown Red and Duckwing Game); W. F. Chickley Buff Cochin).

DUCKS (Aylesbury).—1 J. Drake. 2, A. W. Partridge, Sprowston.

DUCKS (Rouen).—1, F. Parlett. 2, J. Drake.

EXTRA CLASS.—*hc*, J. N. Waite, Norwich (Toulouse Geese, Swans).

PIGEONS.

CARRIERS.—1, F. W. Metcalfe, Cambridge. 2, H. Yardley, Birmingham. *hc*, T. Chambers, Northampton.

BARBS (Dun).—1, K. Morling, King's Lynn. 2, H. P. Dwelly, Peckham.

TUMBLERS.—1 and 2, J. Ford, Monkwell Street, London. *hc*, H. P. Dwelly.

BARBS.—1, T. Beadows, Boston. 2, C. Norman, Ipswich.

FANTAIL.—1, A. A. Vander Meersch, Tottenham. 2, J. F. Loversidge, Newark. *hc*, J. F. Loversidge; H. Yardley.

POUTERS.—1, T. H. Dows, Boston. 2, J. T. Cater, Colchester.

ANY OTHER VARIETY.—1, H. P. Dwelly (Jacks. 2 T. C. Marshall, Peterborough (Magpies). *hc*, J. T. Cater; Col. Cockburn (Black Trumpeters). *c*, H. Yardley.

SELLING CLASS.—1, A. A. Vander Meersch. 2, H. P. Dwelly (Owls).

CANARIES.

NORWICH.—*Clear Yellow.*—1 and 2, J. Mortimer, West Smithfield, London. *hc*, G. & J. Mackley, Norwich; G. Bumbold, Yarmouth. *c*, F. Willis, Norwich. *Clear Buff.*—F. Willis. 2, G. & J. Mackley. *vhc*, J. Mortimer; G. & J. Mackley. *hc*, F. Willis; T. S. Merry, Norwich. *c*, J. Jeffes, Ipswich.

NORWICH.—*Marked or Variegated Yellow*—1, J. Mortimer. 2 and *vhc*, G. and J. Mackley. *c*, F. Willis. *Marked or Variegated Buff.*—1, J. Jeffes. 2 and *c*, J. Mortimer. *vhc*, G. & J. Mackley. *hc*, F. Willis.

NORWICH.—*Ticked or Unevenly-marked Yellow*—1, G. & J. Mackley. 2, J. Chapman, jun., Norwich. *vhc*, J. Mortimer. *c*, F. Willis. *Ticked or Unevenly-marked Buff.*—1 and *c*, J. Mortimer. 2, J. & J. Mackley. *vhc*, J. E. Thirkettle, Norwich; F. Willis *hc*, F. Willis.

NORWICH.—*Crested Yellow*—1, J. Mortimer. 2, J. Jeffes. *Crested Buff.*—1, J. Mortimer. 2, J. Jeffes. *vhc*, E. W. Lulham, Brighton (2). *c*, G. & J. Mackley; Nichols, Norwich.

LIZARD.—*Golden-spangled.*—1, G. N. Harrison, Belper. 2 and *vhc*, G. & J. Mackley. *Silver-spangled.*—1, J. N. Harrison. 2 and *vhc*, G. & J. Mackley.

ANY OTHER VARIETY.—1, R. Poole, Maldon (Buff Cinnamon). 2, G. & J. Mackley (Yellow Belgian). *vhc*, R. Poole; J. Cuthbertson, King's Lynn (Green Canary). *hc*, J. Mortimer (Cinnamon).

SIX CANARIES (Any variety).—1, J. Mortimer. 2, F. Wil is (Norwich). *vhc*, H. Larke, Norwich. *hc*, G. & J. Mackley (Norwich).

SELLING CLASS (Suitable for breeding).—1, F. Willis (Norwich). 2, J. Stannard, Norwich. *vhc*, J. Mortimer; G. & J. Mackley (Norwich). *hc*, W. Bunting.

SELLING CLASS (For the best Canary).—1, G. & J. Mackley (Norwich). 2, W. Nichols. *vhc*, W. B. Hovell, Norwich; W. Bunting. *hc* and *c*, J. E. Thirkettle (Clear Buff and Crested Buff Orange).

SELLING CLASS (Not competing for a prize) — *hc*, J. Quinton, Norwich (Australian Robin Redbreast and cage); J. Stannard. *c*, W. Nichols.

GOLDFINCH MULE.—1 and 2, G. & J. Mackley. *vhc*, J. Jeffes (2). *hc*, E. W. Lulham. *c*, J. Cradwick, Ongar.

ANY OTHER CAGE BIRD (Canaries excluded)—1 and *c*, G. & J. Mackley (Australian Parroquet and Pied Linnet Mule). 2, H. Larke (Goldfinch). *vhc*, J. Banham, Norwich. *hc*, J. Jeffes (Bullfinch).

JUDGES.—*Poultry*: Messrs. Beldon and Adams. *Pigeons*: Mr. J. Percivall. *Canaries and other Cage Birds*: Messrs. Woodhouse, Fenn, and Clarke.

BATHGATE ORNITHOLOGICAL SHOW.

THE Bathgate Ornithological Association held their fourth annual Exhibition and competition of poultry, Pigeons, and Canaries, on the 15th inst., in the Corn Exchange, and the weather being all that could be desired, a great number of the public visited the Show.

The different classes were well represented, and never since the Show was established have we seen such a collection of really good birds. *Dorkings* in both the adult and young classes, though not numerous, were very good, the first-prize birds in both classes having secured similar honours in nearly all the shows they have visited. The adult *Spanish* were a poor class, but of the young the first-prize pen was very fine, and never have we seen such fine faces and combs at Bathgate. This pen also secured the special prize for the best pen in the first three classes. *Hamburghs* were the largest class; many of the birds would not have disgraced a metropolitan show. The first-prize Golden and Silver-pencilled Hamburghs were really fine birds. The Golden-pencilled secured the special prize, but a good many thought it should have gone to the Silvers, as they were better matched than the Goldens. *Game* were not a numerous class, and all the birds appeared rather soft, excepting the Duckwings shown by the now famous Mr. Harley, Edinburgh, which also rightly secured the special prize in the Game department. Game *Bantams*, though numerous, were not so good as those shown here last year, many of them not being in a fit condition for competing.

Pigeons were well represented in nearly all the classes; the first-prize Tumblers and Carriers were remarkably fine. One great feature was an absence of dressing in the Toy classes.

The *Canaries* consisted of the finest birds in Scotland. Most of them had secured similar honours at the different open shows they had visited.

DORKINGS.—1, J. Malcom, Langton. 2, D. Forrester, Linlithgow. 3, J. Young, Bathgate. 4, J. Stephenson, Chapelhall, Airdrie. *Chickens*—1, J. Malcom. 2, J. Waddell, Airdriehill, Airdrie. 3, A. M'Donald, Easter Moffat. 4, J. Brand, Bathgate

SPANISH.—1 and 5, J. Young, Craigneuk, Motherwell. 2, J. Waddell. 3, J. Peat, Bathgate. 4, M. Young, Blackburn. *Chickens.*—1 and Special, J. Waddell, 2, J. Yuill, Airdrie. 3, D. Forrester. 4, Mrs. Gracie, Cobinton.

SCOTCH GREYS.—1, A. Hastie, Wilton, Carluke. 2, A. Dunlop, Paisley. 3, J. Meikleham, Thrashes, Hamilton. 4, W. Gibb, Armadale. *Chickens.*—1, W. Gibb. 2 and 3, J. Meikleham. 4, R. White, Bathgate.

HAMBURGHS.—*Golden-pencilled.*—1 and Special, H. Russel, Cleekmannan. 2, P. Hamilton, Gilhead, Wishaw. 3, H. Chalmers, Bathgate. 4, J. Frame, Motherwell. *Silver-pencilled.*—1 and 2, J. Young. 3, R. Ferguson, Kirkton, Bathgate. 4, H. Chalmers. *Golden-spangled.*—1, J. Waddell. 2, T. Love. 3, J. Young. 4, J. Love. *Silver-spangled.*—1, J. Moodie, Paisley. 2 and 4, D. Forrester. 3, A. Gren, Paisley.

COCHINS.—1, A. Crawford, Airdriehill, Airdrie. 2, J. Stephenson. 3, J. More. 4, J. Peat.

POLANDS.—1, W. Paterson, Airdrie. 2 and 4, W. Gibb, Cambusnethan. 3, A. Wylie, Johnstone.

GAME.—1 and Special, D. Harley, Edinburgh. 2, J. Waddell. 3, R. Gray, Wishaw. 4, A. Flint, Airdrie.

GAME BANTAMS.—1, W. Gibb. 2, Miss J. M. Frew, Kirkealdy. 3, G. Sinclair, Bathgate. 4, R. Rodgers, Bathgate. *Any other Variety.*—1, J. Waddell. 2, Master A. Frew. 3, J. Woodie. 4, J. Muirhead, Airdrie.

DUCKS.—1 and 2, J. Meikleham. 3 and 4, R. S. W. Durham, Bathgate.

TURKEYS.—1, J. Wilson, Riccarton. 2, J. Hamilton, West Calder. 3, D. Prentice, Blackburn.

SELLING CLASS.—1, H. Russel. 2, W. Good, Airdrie. 3, J. Waddell. 4, W. Gibb.

PIGEONS.

POUTERS.—1, 2, and Medal, J. Waddell. 3, R. & J. Anderson, Newcastle-on-Tyne. 4, M'Gil Skinner.

CARRIERS.—1, 3, Special, and Crystal Fountain, J. Brown. 2, M'Gill Skinner. 4, J. Gray.

TUMBLERS.—1, A. Johnstone. 2, J. Brown. 3, R. & J. Anderson. 4, D. Roberts.

JACOBINS, NUNS, ENGLISH OWLS, AND TURBITS.—1, A. Johnstone. 2, Miss B. P. Frew. 3, J. Gray. 4, T. Imrie.

FANTAILS.—1 and Special, J. Baillie. 2, F. W. Christie, Liberton. 3, Miss B. Frew. 4, D. Prentice.

ANY OTHER VARIETY.—1 and 3, R. & J. Anderson. 2, Miss J. M. Frew. 4, T. Imrie.

SELLING CLASS.—1, J. Gray. 2, M'Gill Skinner. 3, R. & J. Anderson. 4, A. Johnstone.

CAGE BIRDS.

YELLOW.—*Cocks.*—1 and 2, W. Mechrie, Lanark. 3 and 4, T. Scott, Carluke. *Hens.*—1, T. Scott. 2, J. Pettigrew, Lanark. 3, D. Duncan, Carron. 4, T. Morton, Linlithgow.

BUFF.—*Cocks.*—1 and Special, J. Pettigrew. 2 and 4, D. Duncan. 3, W. Mechrie. *Hens.*—1, J. Watson, Linlithgow. 2, T. Scott. 3, W. Mechrie. 4, D. Duncan.

YELLOW FIREALD.—*Cocks.*—1, J. Pettigrew. 2 and 3. J. Pender, Edinburgh. 4, T. Scott. *Hens.*—1 and 2, T. Scott. 3, J. Pettigrew. 4, W. Mochrie.

BUFF FIREALD.—*Cocks.*—1 and 2, T. Scott. 3, W. Mochrie. 4, J. Pettigrew. *Hens.*—1, 4, and Special, T. Scott. 2, J. Lyle, Wishaw. 3, J. Furves, Edinburgh.

GREEN OR FOUL-FEATHERED.—1. W. Mochrie. 2, T. Scott. 3, J. Pender. 4, F. M'Gmley, Coatbridge.

JUDGES.—*Poultry:* Mr. J. M'Nab, South Arthurlee, Barrhead; Mr. J. M'Innes, Paisley. *Pigeons:* Mr. James Huie, Glasgow. *Canaries:* Mr. John Smith, Coatbridge, and Mr. Robert Forsyth, Edinburgh.

DUBLIN POULTRY SHOW.

THE following is the list of awards made at this Show, held on the 18th, 19th, and 20th inst. We must defer till next week our *critique*.

DORKINGS (Coloured).—1 and 3, J. Martin, Chines, Worcester. 2, Hon. J. Massy, Limerick. *hc*, Mrs. Warburton, Kill, Naas; S. Mowbray, Kilfiney, Mountrath; G. A. Stephens, Constable of Tankerville, Chillingham Castle. *c*, Mountrath; G. A. Stephens, Constable of Tankerville, Chillingham Castle. *c*, W. H. King, Moss Mills, Rochdale; Rev. E. Bartrum, Great Berkhampstead.

DORKINGS (Silver-Grey).—1, O. E. Cresswell, Early Wood, Bog-hot. 2, Miss De C. Drevar Blackrock. 3 and *hc*, Mr. Warburton. *c*, Hon. J. Massy.

DORKINGS (White).—1, J. C. Cooper, Cooper's Hill, Limerick. 2, No competition.

COCHIN-CHINA (Cinnamon or Buff).—1, H. Lacy, Mulhuddart. 2, Mrs. Allsopp, Hindlip Hall, Worcester. 3, H. Lloyd, jun., Handsworth. *hc*, W. H. Perrin, Loughlinstown. *c*, J. Schiel; Countess of Tankerville.

COCHIN-CHINA (Partridge).—1, C. W. Brierley, Middleton, Manchester. 2, T. Stretch, Ormskirk. *hc*, H. Lloyd, jun.; W. H. Perrin. *c*, G. A. Stephens, Dublin.

COCHIN-CHINA (White) —1 and 2, J. Sichel, Lark Hill, Timperley. *c*, J. F. Bewley, Blackrock.

BRAHMA POOTRA (Dark).—1, H. Lacy. 2, T. S. Ansdell, Cowley Mount, St. Helen's. 3, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. *hc*, Hon. Miss D. Pennant; E. Pritchard; J. C. Cooper; R. W. Boyle. *c*, Mrs. Warburton.

BRAHMA POOTRA (Light).—1, J. R. Rodbard. 2 and 3, M. Leno, Dunstable. *hc*, Rev. N. J. Ridley, Newbury; Capt. Downman, Kingstown. *c*, J. Pares, Postford, Guildford; Capt. Downman; J. C. Cooper.

CREVE-CŒURS.—1, J. Sichel. 2, J. C. Cooper. *hc*, Rev. N. J. Ridley; J. C. Cooper.

LA FLECHE.—1, G. A. Stephens. 2, Rev. N. J. Ridley, Macclesfield. *hc*, Capt. Downman. *c*, J. W. H. Thorp, Macclesfield.

HOUDANS.—1, F. W. Pim, Harold's Cross, Co. Dublin. 2, J. Sichel. *hc*, J. C. Cooper; G. A. Stephens; Mrs. R. K. Clay, Anglesey, Killiney.

SPANISH.—1, E. Jackson, Finchfield, Wolverhampton. 2 and Extra 3, Hon. Miss D. Pennant. *hc*, Hon Miss D. Pennant; E. Finchfield, Wolverhampton; J. Barlow, Appleford Bridge.—1, Mrs. Allsopp; F. H. Jones, Fulham; C. W. Brierley. *c*, Miss De C. Drevar; H. Beldon, Goatstock, Bingley.

HAMBURGHS (Gold and Silver-pencilled).—1 and 2, H. Beldon. *c*, L. Stoney, Sandymount; Countess of Tankerville.

HAMBURGHS (Gold or Silver-spangled). —1, G. & J. Duckworth, Chorch, Accrington. 2, H. Beldon. *hc*, H. Beldon; Countess of Tankerville; G. & J. Duckworth.

POLAND (White-crested Black).—1, Mrs. J. M. Procter, Hull. 2, Miss De C. Drevar. *hc*, P. Unsworth, Newton-le-Willows; R. F. Williams, Glasinin, Clontarf; N. Cook, Chowbent; Mrs J. M. Proctor.

POLAND (Gold or Silver-spangled).—1 and 2, H. Beldon. *hc*, P. Unsworth (2); R. P. Wilhems; H. B. Smith, Broughton, Preston; G. A. Perrin, Loughlinstown.

GAME (Black or Brown Red).—1 and 2, C. W. Brierley. 3, G. F. Ward. *hc*, E. J. Poer, Limerick; G. A. Perrin (2). *c*, J. Cheston, Nantwich.

GAME (Any other variety).—1 and 2, C. W. Brierley. 3, W. Johnson, Stanley, Liverpool; G. A. Perrin. *c*, T. Hadfield, St. Helen's Bay.

BANTAMS (Game, Black or Brown Reds).—1, 2, and Cup, J. W. Morris, Rochdale. *hc*, H. Feldon: G. A. Stephens; H. C. Cullin, Galway; G. A. Perrin; J. R. Robinson, Sunderland.

BANTAMS (Game, any other variety).—1, Rev. F. Cooper, Ampney Crucis. 2, E. J. Poer.

BANTAMS (Any other variety).—1, R. S. Lowndes, Stony Stratford. 2, H. Beldon. *hc*, N. Cook; E. H. Yorkell, Londesborough; M. Leno, Markyate Street (2); J. Sichel. *c*, Mrs. J. M. Proctor; Countess of Tankerville; G. A. Stephens.

DUCKS (Rouen).—1, R. Gladstone, Broadgreen, Liverpool. 2, G. A. Stephens. *hc*, P. Unsworth; R. F. Williams; Mrs. Taylor, Ardgillan, Balbriggan; W. H. Perrin. *c*, Mowbray, Mrs. P. Taaffe, Castle Plunket.

DUCKS (Aylesbury).—1, S. Mowbray. 2, J. C. Cooper. *hc*, R. P. Williams. *c*, Mrs. Warburton. 2, J. C. Cooper. *hc*, R. P. Williams; W. H. Perrin; Mrs. Warburton; Miss C. Chichester, Runnamote, Roscommon. *c*, Mrs. M'Donnell, Glenavin (2).

ORNAMENTAL WATERFOWL.—1 and 2, R. P. Williams. *hc*, R. P. Williams; H. B. Smith; M. Leno (2); J. C. Cooper; Countess of Tankerville; R. W. Boyle.

TURKEYS.—1, Key. N. J. Ridley. 2, Lord Crofton. 3, Miss C. Chichester. *hc*, J. C. Cooper; Countess of Tankerville. *c*, S. Mowbray.

ANY OTHER VARIETY.—1, Rev. A. G. Brooke, Shrawardine. 2, H. Beldon. 3, S. Mowbray. *hc*, R. Done, jun.; Miss Brinkley, Castlenock; J. Sichel, Timperley; W. G. Holt, Church; N. Cook; J. Watts, King's Heath, Birmingham; R. Hawkins, Seaham. *c*, Hon. J. Massey; Mrs. Taylor; Mrs. N. M. O'Donnell.

SELLING CLASS.—1, C. W. Brierley. 2, G. Furness. 3, S. Mowbray. *hc*, J. K. Milner, Cherbury, Blackrock; J. Barlow; S. R. M'Gee; Mrs. Warburton; C. E. M'Garrick, Crumlin. *c*, Mrs. P. Taaffe; F. W. Pim. *c*, Mrs. N. M. O'Donnell; Mrs. Warburton; J. C. Cooper.

SPECIAL PRIZES (Lord Lieutenant's Prizes).—1, M. Barlow. 2, Miss Marmion, Phœnix Park, Dublin. 3, J. Barlow. *hc*, F. Smith, Mulhuddard; Miss Marmion; C. Dillon, Chapelizod. *c*, P. Smith; Miss Marmion.

SINGLE COCKS.

DORKINGS.—1, J. K. Milner. 2, Mrs. Warburton. *hc*, J. C. Cooper.

SPANISH.—1, Mrs. Allsopp. 2, Hon. Miss D. Pennant. *hc*, Hon. Miss D. Pennant; C. W. Brierley.

GAME.—1, C. W. Brierley. 2, W. Johnston. *hc*, C. A. Perrin (2); G. F. Ward, Wrenbury.

COCHIN.—1, Mrs. Allsopp. 2, H. Lacy. *hc*, H. Lloyd, jun., Handsworth; W. H. Perrin (2).

BRAHMAS (Dark).—1, H. Lacy. 2, Hon. Miss D. Pennant. *hc*, Hon. J. Massy; Mrs. Warburton; L. F. Perrin. *c*, Mrs. P. Taaffe.

BRAHMAS (Light).—1, Capt. Downman. 2, J. C. Cooper.

HOUDANS.—1, J. C. Cooper. 2, Withheld.

CREVE-CŒURS.—1, E. J. Poer. 2, J. C. Cooper.

HAMBURGHS (Pencilled).—1, H. Beldon. 2, L. Stoney.

HAMBURGHS (Spangled).—1, H. Beldon. 2, No competition.

GAME BANTAMS.—1 and 2, J. W. Morris, Dublin. *hc*, G. Maples, jun., Waverree; G. Furness, Rawtenstall; J. R. Robinson; Ashley & Maitland; W. Adams, St. Clements, Ipswich.

ANY OTHER VARIETY.—1, J. K. Milner. 2, H. Beldon. *hc*, Capt. Downman; A. B. Dick; S. Mowbray.

PIGEONS.

POUTERS (Blue Pied).—*Cocks.*—1, J. Wallace. 2, F. Gresham. 3, J. Montgomery; F. H. Jones. *c*, E. Horner, Harewood, Leeds. *hc*, J. Montgomery (2); P. H. Jones. *c*, J. Montgomery. *Hens.*—1, Cup, and *hc*, J. Montgomery. 2 and *hc*, F. Gresham. 3, E. Horner.

POUTERS (Black Pied).—*Cocks.*—1, Cup, and *c*, J. Montgomery. 2, F. Gresham. 3, J. Wallace, Glasgow. *Hens.*—1 and 3, J. Montgomery. 2, F. Gresham. *hc*, E. Horner.

POUTERS (Red Pied).—*Cocks.*—1, *vhc*, *hc*, and *c*, J. Montgomery. 2, J. Wallace. 3, E. Horner. *Hens.*—1, J. Wallace. 2 and 3, J. Montgomery. *c*, E. Horner.

POUTERS (Yellow Pied).—*Cocks.*—1 and 2, J. Montgomery. *Hens.*—1, J. Montgomery. G. A. Wallace. 3, E. Horner.

POUTERS (White).—*Cocks.*—1, J. Wallace. 2, F. Gresham. 3, J. Montgomery. *vhc*, E. Horner. *hc*, F. W. Zurhorst. *c*, J. Montgomery; F. W. Zurhorst. *Hens.*—1 and 2, J. Montgomery. 3, E. Horner. *vhc*, P. H. Jones. *hc*, F. W. Zurhorst.

POUTERS (Any other colour or marking).—*Cocks.*—1, J. Lohore. 2, F. W. Zurhorst. 3, J. Montgomery. *Hens.*—1, 2, and *c*, F. W. Zurhorst. 3, T. Rule, Durham.

CARRIERS (Black).—*Cocks.*—1 and 2, J. Montgomery. 3, J. C. Ord. *hc*, Col. Hassard, Curragh Camp; E. Horner. *Hens.*—1 and Cup, E. Horner. 2 and 3, Col. Hassard. *Young Pair.*—Cup, E. Horner. 2, J. Montgomery. 3, G. A. Wheland. *hc*, Col. Hassard. *c*, G. A. Wheland.

CARRIERS (Dun).—*Cocks.*—1, J. C. Ord, Lupus Street, Pimlico. 2, E. Horner. 3, G. A. Wheland, Cork. *hc*, J. Montgomery; Col. Hassard. *Hens.*—1 and 2, J. C. Ord. 3, E. Horner. *c*, J. Montgomery.

CARRIERS (Any other colour).—*Cock.*—1, E. C. Stretch, Ormskirk. 2, J. Watts, Birmingham. 3, Col. Hassard. *Hen.*—1, J. C. Ord. 2, J. Watts. 3, Col. Hassard. *Young Pair.*—1, Col. Hassard. 2, G. A. Wheland. 3, G. Hodgkinson, Erdington. *hc*, J. Montgomery; J. Dowling.

TUMBLERS (Almond).—1, Cup, and 3, J. Ford, Monkwell Street, London. 2, J. Fielding, jun., Rochdale. *hc*, J. Wallace. *c*, E. Horner.

TUMBLERS (Any other colour).—1, F. H. Jones. 2, G. Smith. 3, E. A. Seale, Kilgobbin, Co. Dublin.

BARBS (Black or Dun).—1, Cup, 2, and *hc*, J. Montgomery. 3, J. Dowling, Blackrock, Cork. *c*, J. Wallace; E. Horner.

BARBS (Any other colour).—1, J. Montgomery. 2, J. Dowling.

BARBS.—*Young.*—Cup, J. Montgomery. 2, J. Wallace. 3, G. A. Wheland. *hc*, J. Montgomery; J. Dowling.

JACKS (Red or Yellow).—1 and Cup, J. Lohore. 2, F. W. Zurhorst. 3, R. W. Smith. *hc*, J. Thompson, Bingley; F. Waith. *c*, E. Horner.

JACKS (Any other colour).—1, W. E. Van Haansbergen, Newcastle-on-Tyne. 2, E. A. Seale. *hc*, J. Thompson. *hc*, E. A. Seale; W. E. Van Haansbergen.

FANTAILS.—1, J. Sharp. 2 and 3, E. A. Seale. *hc*, E. A. Seale; E. Horner.

NUNS.—1, F. H. Jones. 2, J. Watts. 3, E. Horner.

TRUMPETERS (Black or Dun).—1 and Cup, 2, and *c*, J. Montgomery. 3, J. H. Perrott.

TRUMPETERS (Any other colour).—1 and 3, E. Horner. 2, J. Montgomery. *hc*, J. Montgomery (2); J. H. Perrott.

TURBITS.—1 and 3, E. A. Seale. 2, H. L. Tivy. *hc*, J. Fielding, jun. *c*, P. H. Jones; G. E. Stretch.

OWLS (Foreign).—1 and 3, J. Fielding, jun. 2, E. Horner. *hc*, P. H. Jones. *c*, E. C. Stretch.

OWLS (English).—1 and Cup, T. M'Donnell. 2, F. W. Zurhorst. 3, W. Johnson.

MAGPIES.—1, J. Dowling. 2, H. Feldon. 3, L. F. Perrin. *hc*, E. Horner (2).

DRAGOONS.—1 and Extra 3, G. South. New Bond Street, London. 2, P. H. Jones. *c*, E. Horner; S. Holroyd.

JONES. 3, F. Graham. *hc*, G. South (2); P. H. Jones. *c*, E. Horner; S. Holroyd.

ANTWERPS.—1 and 3, F. W. Zurhorst. 2, E. Horner. 3, G. South. 3, E. C. Stretch. 4, J. Any other variety.—1, E. Horner. 2, G. South. 3, E. C. Stretch. 4, J. Thompson. *c*, T. M'Donnell; H. Beldon.

SELLING CLASS.—1, P. H. Jones. 2, H. Beldon. 3 and 4, E. A. Seale. *vhc*, R. W. Smith. *c*, J. K. Milner; E. A. Seale; H. Beldon (2); R. W. Smith.

POUTER PAIRS, EXCLUSIVE OF POUTERS, CARRIERS, AND TUMBLERS.—Cup, W. E. Van Haansbergen. 2, P. H. Jones. 3, E. A. Seale. *hc*, J. Dowling. *c*, N. Morton.

CANARIES.

BELGIAN (Yellow).—1, M. Sheridan. 2, J. Morris. *hc*, F. Smyth, Dublin; W. Donegan. *c*, P. Kearns; G. Young.

BELGIAN (Buff).—1, M. Sheridan, Dublin. 2, G. Young, Dublin. *hc*, W. Donegan, Dublin. *c*, J. Belton. *hc*, P. Kearns.

NORWICH (Yellow or Buff).—1, W. H. Culverhouse, Dublin. 2, J. Belton. *hc*, P. Kearns. *c*, F. Wright, Dublin.

LIZARDS (Green).—1 and *c*, J. Heaps, Dublin. 2, F. W. Zurhorst. *vhc*, J. Morris, Dublin. *hc*, J. Belton, Dublin (2); W. H. Culverhouse.

RADDISHES.—1, M. Sheridan. 2, P. Kearns. *c*, G. Young.

LONDON FANCY OR OTHER VARIETY.—1, P. Kearns. 2, Miss Millar, Monkstown. *hc*, F. Wright; P. Quinn.

GOLDFINCH OR LINNET MULES.—1 and 3, J. Morris. *hc*, F. Wright; P. Quinn, Rathmines. *c*, J. Perrin.

MIGRATORY BIRDS.—1, P. Kearns. 2, P. J. Mullen, Dublin.

CARDINAL FINCHES AND VIRGINIAN NIGHTINGALES.—1, J. Morris.

FOREIGN (Any other variety).—1, P. Kearns. 2, T. Beatty, Dublin. *c*, P. Kearns; R. J. Mullen.

JUDGES.—Mr. Edward Hewitt, Mr. R. Teebay, Mr. W. Betegetmeier, Mr. J. Frame.

SELKIRK POULTRY SHOW.

As regards numbers and quality this was the best Show ever held at Selkirk, there being nearly three hundred entries. The Rifle Drill Hall, in which the Exhibition was held, is an excellent place for the inspection of the birds, as the light is good and equal in all parts. Besides three money prizes in each class for pairs of birds, twelve handsome timepieces were offered as extra prizes for competition among the cock birds only in both the poultry and Pigeon classes.

The *Spanish* were fair on the whole, and both classes of *Dorkings* were very good. The special prize was won by an ex-*Dorkings* were very good. The first prize for cellent Silver against a very fine Dark Grey. The first prize for *Cochins* went to Partridge, which won the special prize from the *Cochins* went to Partridge, which won the special prize from the *Brahmas*. The latter were of the Dark variety. The first-prize cockerel in this class was very good and in excellent condition. Of the Silver-pencilled *Hamburghs* only one pen was good, the rest being worthless; but the Golden were much better, and the timepiece was awarded to the second-prize cockerel. The and the timepiece was awarded to the second-prize cockerel. The second Spangles of both colours were exceedingly good, and the special Spangles of both colours were exceedingly good, and the special Spangles of both colours were exceedingly good, and the special prize went to the Golden-spangles. There were four classes for prize went to the Golden-spangles. There were four classes for prize went to the Golden-spangles. There were four classes for *Bantams*, and the birds throughout were very good, but again to some extent spoiled by being placed in open pens. The timepiece was awarded to a Black cockerel, which was about

the most perfect that has been seen this season, and the pen was entered at the low price of £5. The Crêve-Cœur cock which was first in the Variety class was awarded the special prize against Spanish; and in *Ducks* the Aylesbury carried off the palm. The Selling class offered an excellent opportunity for purchasers.

If the classification was well carried out in poultry, it applied much more forcibly to the *Pigeons*. Tumblers, Fantails, and Jacobins competed for the first special; Carriers, Pouters, and the Variety class for the second; Nuns, Owls, and Turbits for the third; and for the awards we refer to the list. In Tumblers, Almonds were first and second, Piles third, and the quality of head, beak, and eye was very good. There were but four entries of Carriers, but the first-prize pair were of high character in all points. Fantails, as may be expected across the border, were very good in style and carriage. Mr. Park won with a pair in the highest order. Those of Mr. Loversedge appeared to be considerably overshown and out of condition, doubtless partly owing to their long journey. The first-prize Jacobins were Red, very good in hood and chain; the second White, a little too open in chain, but otherwise perfect; and the third good Reds. Nuns were good and the competition close; and the Owls one of the best classes in the Show, the first being Black Foreign, the second Whites, and the third Blue English. Of Turbits the Blues were first and Reds second, both pairs being perfect. In the Variety class the first were Black German Letz, the second Ice Pigeons, the third Black Barbs. Excellent Blue and White Dragoons, Ice, and Frillbacks were highly commended, and the Selling class was exceedingly well filled.

Unfortunately the wetness of the first day interfered with the receipts at the gates.

SPANISH.—1, J. Thresby, Bradford. 2 and 3, D. Waugh, Melrose. 4 and c, J. Laidlaw, Langholm.

DORKINGS.—1, Special, and 4, D. Hardie, Friesthaugh, Hawick. 2, J. White, Warlshy. 3, H. Stephenson, Tillyfour, Aberdeen. *hc*, J. Mathison, Selkirk. *Chickens.*—1, J. White. 2, D. Hardie. 3, W. Swaun, Bedlington. 4, F. L. Roy, Nenthorn, Kelso. *c*, J. Fotheringham, Dalbeattie; A. Inglis.

COCHIN-CHINA.—1 and Special, J. White, Whitley, Wakefield. 2, J. Pollock, Glasgow. 3, J. Brown, Hull. 4, R. Hind, Morpeth. *hc*, Mrs. T. Brown.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

SHERRINGTON BAR HIVE.

PERHAPS you will not object to publish a few words from me on the great advantage the bar hive has over the common hive, particularly if it will induce masters to procure a hive as a pattern to show to their labourers.

Cottagers, and those who keep bees to help out small means, naturally wish to obtain the largest possible amount of honey. When, in August, the supers have been taken, and the bees have done storing honey for their owner's profit, he naturally looks for a little extra profit by robbing the strong stock hive. How far easier it is to extract three or four combs from a bar hive than to cut them out from a common hive! In the one case, with the help of a few puffs of smoke, the four bars are removed in double the number of minutes, the bees are uninjured, and the remaining bars unshaken. In the other case it is a task requiring considerable nerve, the help of an assistant, and too often attended with more damage to the combs than profit to the owner. To a poor man the question, But the cheapest is often not really the cheapest in the end. With the common hive he would have generally to be content with what honey was in the supers; but with the bar hive the honey taken out would in the first year pay the additional expense of the hive, and for ever afterwards it would be a source of increased profit. A man has only to work this out by placing a common hive beside a bar hive to practically test the truth of what I say. There are many bar hives, and he can buy which he likes. I have planned the Sherrington bar hive cheap, for poor people. After seeing one, any man handy with fingers and saw could make all he would want for himself, during winter evenings, at the expense of the material, which could not cost more than 3*s*. I should think the expense of such work is the time occupied in the making. I should describe more fully the method of construction, had I felt myself competent to teach another to make by written description what I was unable to teach my own carpenter to make at first try from word of mouth.—T. W. GODDARD, *Sherrington.*

OUR LETTER BOX.

EGG-EATING FOWLS (——).—Your fowls eat their eggs because they are out of condition. Throw down loads of bricklayers' rubbish, and give them cooling green food. It is very difficult to cure. You can discourage the practice of eating eggs by putting very hard composition eggs in all their haunts. They get tired of trying to eat them.

CHINESE FOWLS (*G. C. A.*).—We are sorry we cannot help you to find the names of your fowls. We can only repeat that but for the top-knot, or rather lark-crest at the back of the cock's head, we should call them Black Cochins.

SHED FOR FOWLS (*E.*).—An open shed is preferable to a closed one as a run for fowls. If they are allowed entry into their house they will go there if the weather is too severe for them out of it, and it may safely be left to their discretion.

LAME TURKEY (*A. M. L.*).—He is probably a heavy bird, and in flying from his perch he has bruised the ball of his foot. This would present no visible appearance. The best treatment will be to confine him in a place well littered with straw. He will be long in recovering while he is at liberty. The weight of his body makes it difficult, as it falls on the tender spot each time he puts his foot to the ground.

HEN'S EGG-POUCH HARD (*W. T.*).—If the whole of the egg-pouch and its adjacent parts are hard to the touch, we advise you to kill the hen; the disease is an internal one and incurable. If it is merely cutaneous, soften with grease, wash with soap and water till the excrescences can be removed, then treat with healing ointment. The bird must be shut up till the cure is perfect, as nothing perpetuates and increases it so much as dirt.

PLUMAGE OF GOLDEN-SPANGLED HAMBURGHS (*A Beginner*).—The best Spangled Hamburghs we ever had showed white tips to their feathers on their bellies, and the cocks at times on their thighs. The latter is a far more serious defect than the former. We hope the exhibitors will forgive us for telling the truth, that it is a common thing for the white tips to be coloured. It would, of course, be far better if they did not exist. A white feather would be an abomination, but we can only repeat, the best and most successful strain we ever knew was subject to these spots. There was no breeding-in, nor other degeneracy.

CUCKOO DORKINGS (*H. A.*).—We are glad you have the Cuckoo Dorking, no better fowl lives, and they are at home in Surrey, which is their native air. Crève-Cœurs lay large eggs and lay well, but they are subject to periods of sickness from which they recover, but they are very miserable while such last. Houdans lay smaller eggs, but quite as many, and they are never sick nor sorry. We keep hundreds of Brahmas and do not find them large eaters, we consider them one of the most useful fowls we have. Spanish lay beautiful eggs for size, appearance, and flavour, but they are delicate chickens to rear, and they are scarecrows for a long time when moulting. Of the three breeds you mention, we should advise Houdans.

POULTRY RUN AND HOUSES (*V. G. C.*).—You can keep fowls by throwing the two runs into one, thus making it 24 feet by 8 feet. It is a pity the houses are not higher. One is sufficient for the number of fowls you can keep, as if you have no other space you will not rear chickens. If you have a kitchen garden in which you could put a hen under a rip with her chickens, the latter, of course, having the free run, then you may accomplish it. The spare house would do for a store, and for two or three sitting hens. You may in the space keep a cock and six hens. We should recommend you Brahmas if you mean to try chickens; Crève-Cœurs, Houdans, or Spanish if you do not. These last do not sit. You must bear in mind that in confined spaces you must seek to provide them artificially with that which they get in a state of nature, and which is essential to them—green food; the most useful is a daily large sod of growing grass cut with plenty of earth, dust, road grit in which to bask, and a heap of bricklayers' rubbish. You must be careful not to overfeed.

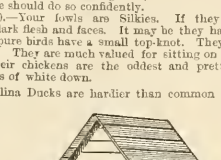
GAME COCK (*C. J. S.*).—We are disposed to believe you have one between a Black Red and a Duckwing, or between a Black and a Duckwing. This latter cross is often tried where a tendency has been shown on the part of the Duckwing to throw white spots or grey feathers in the breast. The objectionable parts are bred out, and sometimes the first crosses are sold. It may be you have one of them.

DISTINGUISHING THE COCK FROM HEN GUINEA FOWL (*J. K.*).—There is no certain test. The "comeback" is not one. The knob on the head of the cock is larger than that of the hen, and the gills are larger and drop lower. This cannot be depended upon, as those of an old hen sometimes become greatly developed. If it is intended to breed them, there is no certainty unless they are kept in pairs.

TWO COCKS WITH FORTY-FOUR HENS (*W. H. P.*).—You want two more cocks now and for the next month, after that one more would be enough, and in the hot weather two would do. Go on sitting now, and a week after the introduction of fresh cocks we should do so confidently.

WHITE FOWLS (*Tamberlique*).—Your fowls are Silkies. If they are thorough-bred they should have dark flesh and faces. It may be they have a stain, but they are Silkies. The pure birds have a small top-knot. They are good layers and excellent sitters. They are much valued for sitting on Partridge and Pheasant eggs. Their chickens are the oddest and prettiest things imaginable, being like balls of white down.

CAROLINA DUCKS (*Chee*).—Carolina Ducks are hardier than common wild Ducks. They feed freely on barley, Indian corn, and buckwheat. They do not require a large run. A few feet of grass extending from the water all round is the most they require. They should be pinioned, then they cannot fly. They are not wanderers. They breed freely in England. They will not make nests nor lay on the ground. They require small boxes shaped like dog-kenuels, to be fastened on poles in the water, as in the accompanying figure. They will lay and hatch in them.



PIGEONS "GOING LIGHT" (*R. H. Keable*).—This disease, otherwise called consumption, has been sadly prevalent during the present season, possibly from the great damp. We believe there is no remedy known. We invite the opinion and experience of the fancy on this subject.

POINTS IN NUNS (*Jack*).—We believe the right number of dark feathers in each wing should be six, some say seven. Your birds having more on one wing than on the other would not win. Their being free from black feathers inside their hood is a great excellence, also their having no foul feathers in the body. Breed on until you breed birds with a level number of flight feathers, and you will have a good chance of a good prize. Jacobins should not have white thighs.

CANARY AND GOLDFINCH CROSS (*S. J. N.*).—The age is immaterial, the main object being to get a hen from a strain which, from some inexplicable cause, has a tendency to throw birds more nearly allied to the Canary in plumage than to the Finch. By far the greater proportion of Goldfinch Mules are dark, self-coloured birds, not half so bright in plumage as the Finch himself; but where the Canary shows itself, either by giving brilliancy of colour to the naturally dark feathers of the self-coloured bird, or by causing it to break into a beautifully variegated specimen, the Mule becomes valuable according to the amount of brilliancy so bestowed, or the exactness of the markings; or if the Mule be perfectly clear, a cock of good colour, if it have a bright blaze on its face the breeder may write himself down among the lucky men of the nineteenth century. I can give no opinion as to the best age for pairing Canaries. Breeders never wait for breeding stock to reach any particular age. You cannot go far wrong by following Nature, but put your birds up in the spring, about the time when they are beginning to make love out of doors. Young birds of last season will breed this year, and breeders are only too glad to get nests from them while in the full pride of their strength. I have read somewhere, I do not know where, that certain disparities in the ages of the sexes have a tendency to produce more cocks or more hens in a nest, as the case may be, but I have never recorded any statistics, and seldom relate any experience but my own.—W. A. BLAKSTON.

CANARIES UNWELL (*H. C. W.*).—The cage of the Canary No. 1 is infested with a very familiar insect, the *Pediculus*, a parasite which ——. I was going to attempt a learned disquisition on the nuisance, but the truth is, I know nothing of the natural history and private life of these pests. I only know them by sight, and when they intrude am always desirous to cut the connection. I said parasites, and that, I apprehend, they must be. *Ex nihil nihil fit*, and I do not see how wood, wire, paint, and varnish can by any fortuitous combination produce animal life. They must emanate from the bird; but what they are, what they turn to (if they turn to anything at all), or whither they go, is more than I can say. When I get a visitation they usually go into boiling water. One year I put away some felt nests without examining them—very careless, I admit, but at the close of a busy season one is glad to get the rubbish out of the way and clear up for moulting—and I found them some time after completely perforated, tunnelled by some long maggotty-looking worms, which I fancied were one form of the red insect, mite, spider, bug, or by whatever name it may be called. They congregate in masses round the inside of nests, in cracks, between cages in contact, in any snug corner, and there they multiply and increase in a wonderful way. They do not show themselves much till nightfall, when they emerge from their dens and feast on the blood of the Canary, and if a cage infested with them be examined by candlelight, they may be seen running over the feathers of the birds by scores, with a nimbleness and activity quite foreign to them in the daytime. However, your cage seems to be infested with them, and the best thing will be to get rid of them, and study their natural history afterwards. This will best be done by immersing it in boiling water, and afterwards varnishing it, taking care to rub the varnish well into the cracks and joints. Is No. 2 in a cage by itself? Are the tips of the young feathers injured by any other bird pecking it, or by its knocking itself about? From the length of time it has been in its present state, I apprehend it has been making a late moult. But the half-closed eyes and general debility point to a state of things which can only end one way unless a change for the better occur. Cover it up entirely with a piece of green baize or other warm stuff, and place it in an extra warm place. Take away its water for half a day and replace the vessel with the surface well floated with castor oil. Feed on Canary seed only.—W. A. BLAKSTON.

CANARY'S EYE BLIND (*Laicc*).—If the complaint is of six months' standing, it says little for any prospect of recovery. It must be the result of old age, or causes other than temporary inflammation from cold.—W. A. BLAKSTON.

HUSK IN CANARY (*D. H.*).—Give bread and milk, and hang in a warm place away from draughts.—W. A. BLAKSTON.

NUTT'S HIVE, &c. (*Subscriber's Sister*).—Write to Messrs. Neighbour, 127, High Holborn. They can inform you better than we can.

UNHEALTHY HIVE (*Alpha*).—We should imagine your bees have been suffering from dysentery. We shall be better able to advise you if you will favour us with replies to the following questions. 1, Was the hive very light when you united the bees? 2, How much food did you give? 3, Do the bees fly out at all on warm days? 4, What appearance and substance do the yellow combs (as you express it) present?

VARIOUS (*Stultus*).—The Mountain Finch, Bramble Finch, or Brambling, is the Fringilla montifringilla of ornithologists. You will find it described in Macgillivray's "British Birds." Oatmeal and ground oats are not the same. We do not know what you mean by "an ordinary out-door grape," nor do you say where your vine is growing.

MELLIOTUS LECANTHA (*H. B. S.*).—You must raise plants from seed. You can obtain it of any agricultural seedsman. All the clovers and melliots are good bee-flowers.

FIXTURES (*W. B. B.*).—You have no legal right to remove the grate and copper without your landlord's consent.

REMARKS.

17th.—Very rainy morning, and so continued all day, the wind getting more and more boisterous till night, when it blew a gale.

18th.—Fine morning, rain about noon, and in the afternoon, but fine between, and lovely night.

19th.—Beautiful bright sunny morning, dull afternoon, fine evening with lunar halo at 5.30 P.M., but dull night.

20th.—Wet in morning and showery during the day, fine evening and very fine

21st.—Slight mist early, then dry, rain at 0.40 P.M., fine afterwards, but damp and disagreeable.

22nd.—Stormy, dark, and damp all day.

23rd.—Wet and windy morning, but fine from noon, all the afternoon and evening. Lunar halo at 9.20 P.M., and rain at 10.30 P.M. Barometer remarkably low at 1 P.M., reading corrected and reduced to sea level only 28.832.

The week has been as damp and cloudy as most of the last month, and the barometer very low, below 29 inches twice—viz., on the 18th at 2 A.M., and 23rd at 1 P.M.

24th.—Shortly before midnight the barometer again turned to fall; and at 4.47 A.M. on the 24th it was, corrected and reduced to sea level, only 28.332 inches being lower than for the last 25 years, and with, I believe, one exception the lowest for half a century.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 24.

We have still an excess in the supply of rough out-door produce, and reduced prices have been the consequence. Forced vegetables are quite sufficient for the trade. Cornish Broccoli is very good. Consignments to us from Paris chiefly consist of salading; the general trade with the Continent has been large this week.

From observations taken near London during forty-three years, the average day temperature of the week is 45.4°; and its night temperature 32.8°. The greatest heat was 57°, on the 3rd, 1850; and the lowest cold 10°, on the 5th, 1830. The greatest fall of rain was 0.67 inch.

WHY DO GRAPES FAIL?

WE agree with the epigrammatic remark of Mr. Pearson (page 17) that "a man may miss his way in the cultivation of a new kind of fruit without being exactly a fool." There are circumstances connected with the cultivation of the Vine which even the best gardeners do not think of or cannot control, and therefore it becomes everyone to speak with some degree of diffidence and modesty in condemning new kinds of Grapes till they have had a fair trial, and the greatest skill has been exhansted npon them unsuccessfully.

To the uninitiated it seems very bewildering that at one place Mrs. Pince's Muscat, for instance, is grown in the greatest perfection, while at another place only a few miles distant it proves a complete failure, after having tested the best exertions of its owner in its favour; and such is the case. Instances of this not only in regard to this Grape but to many others may be furnished; but it is rash in those who fail, to condemn in unmeasured terms, as has been too frequently the case lately, those varieties which, from whatever cause, they cannot grow.

It would be well worth while, and much advantage might result from the inquiry, to ascertain where certain kinds of Grapes succeed and where they fail; then to set an investigation on foot as to the soils of the districts where they are grown. A great deal has been said about the formation of Vine borders; much has been written about them, and some sharp controversies have taken place on the subject. In almost all, if not all, the instructions as to how a Vine border is to be made, we are told to "take the top spit of an old pasture." Now, in this top spit of an old pasture resides many a success and many a failure. Have those who so unreservedly advise taking the top spit of an old pasture ever reflected what that really means, and to what results their advice must unfailingly lead? Let us take a few spits from the surface of old pastures—one from Hampstead Heath, and another from Bagshot; one at Oxford, another at Cambridge; from the Weald of Sussex, and from the Forest of Exmoor; from a valley in the Cheviots, and from the banks of the Tyne; from Ipswich, from Matlock, and from Aberystwith. Analyse these separately, and we shall find in them substances as various in their mechanical and chemical composition as it is possible for them to be.

Now, while there are varieties of the Vine that will grow more or less successfully in all these kinds of soil, there are others much more capricious, and which require to be studied in this particular if their greatest merits are to be brought out. The *vignerons* of Europe have long ago discovered that to get the greatest good from certain varieties they must be grown on certain soils. The plants that produce the finest growths of Champagne are not grown on the rocky steeps and valley slopes of the Rhine; and those which supply the vaunted Johannisbergs and Rüdesheimers are very different from those yielding the Montrachet of Burgundy and the Yquene of the Gironde; while the Carmenet, the Malbec, and the Verdot, to which we are indebted for the famed Margaux, La Rose, and Lafitte, are entirely ignored in Burgundy, where they would fail to yield the equally famed Romanée Conti, Chambertin, and Clos Vaugeot furnished by the little Noirien and Pineau. It is, therefore, evident that to insure success in the cultivation of the Vine, our growers must give more heed to the composition of the soils of which their borders are made; and also to learn the kind of soil in which the different varieties are found to succeed best. One of the Grapes, respecting which regrets are frequent because it is so difficult to grow, is the Muscat Hamburgh, one of the most excellent varieties known in regard of flavour. This has the reputation of being in some places a bad grower, in others a bad setter, and not unfrequently bad to colour. A few years ago we sent it with others, then new here, to the south of France, where it is now being largely grown in vineyards on the schistoze spurs of the Pyrenees, and where neither in point of growth, fertility, colour, nor flavour does it leave anything to be desired. There, then, is a proof that the Muscat Hamburgh delights in a soil formed of the rocks of the primary formation. No doubt many other Grapes require special soils and treatment, and it is to attain a knowledge of these that gardeners ought to direct their attention.

We have been led to make these observations in consequence of a tendency exhibited by some writers lately to run down and disparage some of the new Grapes recently introduced, merely because of their own or of others' failures to grow them. Not content with depreciating the Grapes, they even point innendoes at the raisers and introducers of them; innendoes that cause honourable traders to shrink and reproach themselves that they have been the means of disseminating such worthless commodities. Nothing can be more unfair and unguarded. Such conduct acts as a check to enterprise, and a discouragement to experiment. It is hasty, thoughtless, and mischievous. If growers would content themselves with simply giving their experience, and stating all the circumstances under which the fruit was produced, others might learn what to do and what to avoid; but an unqualified condemnation merely on the ground of individual failure, though it may not bring the writer under the charge of what Mr. Pearson calls being "a fool," lays him open to be considered extremely foolish.

AMARYLLIS AND HIPPEASTRUM CULTURE.

The plants to which I would now call the attention of amateurs are usually to be found in gardens under the name of Amaryllis, although it would, perhaps, be more correct to place them in the genus Hippeastrum. The true members of the former genus are mostly natives of the Cape of Good Hope, and have but few representatives in the gardens of Europe, whilst the latter, although nearly allied and almost similar in appearance, are mostly found in tropical America and the various West Indian islands, and, together with the hybrid forms to which they

have given rise, are happily more frequently to be met with in our plant stoves, and upon our exhibition tables, but, certainly, much less frequently than they deserve to be. I think, therefore, it is quite time the subject should be agitated through the pages of the Journal, in order to arouse the latent fire of those who were once admirers of these plants, but who may have been seduced from their old love by more popular modern beauties, also to endeavour to enlist young rising amateurs in the ranks of the Hippeastrum-growers.

If any of my readers think it an innovation on my part, or refuse to relinquish the name Amaryllis from what I have said, I no more wish to ask them to do so than I have means to enforce it; but I do say, Grow these plants extensively, call them whatever you please, but cultivate them largely, and hybridise them also, so that some of your fellow labourers may be gladdened with the sight of new forms.

Those amateurs who delight in grand showy flowers should lose no time in adding some of these plants to their collections, for they are most accommodating in their nature, and are very easily managed. They are equally suitable for growing and flowering in the stove, greenhouse, or fernery; but those who have the advantage of a stove temperature and a moderate quantity of bulbs may, with a little management in arranging the succession, enjoy the beauties of these gorgeous flowers every month, if not every week, in the year, thus giving a more brilliant return for the little attention bestowed than some plants do for a whole season's unremitting care. I do not wish, be it understood, to advocate the culture of those plants only which require little attention; for if I know anything of the genuine love of plants after twenty-six years' courtship, I must say I have yearned for the health of, and fondled most, the very plants that I have found most difficult to manage. With amateurs, however, in many instances, the case must be very different; for if it be only possible to devote to their plants a certain amount of time daily, then it behoves them, if success is looked for, to cultivate those plants only which can accommodate themselves to the limited time at their disposal.

These plants, I am sorry to say, are treated in what appears to me a very irrational manner, for in a state of nature the bulbs grow below the surface of the soil, but under cultivation they are placed upon the top, or at most only partially covered, but the reason for such a change I never heard satisfactorily explained. That they will grow with us and flourish when treated in a natural manner is an undeniable fact, and certainly they then present a more elegant appearance than they otherwise do. Again, when the growing season is past, the usual practice is to turn the pots upon their sides, and completely dry up the roots; nay, some even go to a greater extreme and turn the bulbs out of the pots, placing them upon dry shelves. This I cannot help thinking most unnatural treatment, and one of the reasons why we do not see much improvement from year to year in these plants. Friends of mine, who have collected them, have assured me that in the dry season they have dug out the bulbs with their roots deep down amongst the moist soil, and quite active. That under similar treatment Amaryllids thrive with us I may cite my old favourite A. Belladonna, which, when planted in the open ground, especially under a wall, grows and flowers most luxuriantly, each year only serving to increase its vigour and the number of its flower-scapes; yet plants exactly similar, but not rejoicing in such a hardy constitution, have the majority of their roots dried up every season, and, consequently, are prevented from displaying themselves in their best aspect.

The method I adopt in the cultivation of these bulbs, and which has led to very successful results, is to pot them below the surface of the soil, using for this purpose a compost consisting of two parts good turfy loam, one part leaf mould, and one part thoroughly decomposed manure, adding to the whole sufficient sand to make it feel gritty when taken in the hand. The most suitable time for repotting I consider to be immediately after the flowers fade. During the growing season they enjoy a liberal supply of both heat and moisture, and therefore the drainage must be perfect. Growth completed, and the leaves showing signs of decay, water should be gradually withheld; and when the plants have become dry, inure them by degrees to a lower temperature, until ultimately they may be placed in a cold pit. While there no water should be given, but a little water may occasionally be poured into the pit between the pots, by which means I have generally preserved most of the roots, so that when the plants begin to push up their flowers there are active mouths all ready to supply nutriment to the awakened plant.

In drawing my remarks to a close, I will add a few names of kinds I have grown, with the colours of their flowers, to assist some of my readers in making a selection. At the same time it must be understood there exist an immense number of hybrid forms, although they are somewhat difficult to procure. This drawback to their culture is, however, fast fading away, as several of our leading London nurserymen are devoting their energies both to the introduction of species and of good hybrid kinds.

La Beauté.—A beautiful white flower, the segments striped with crimson.

Gravianum.—Ground colour orange red, base of flowers light, segments striped with white.

Sir John Franklin.—Greenish yellow, with deep crimson edges.

International.—Segments very long; flowers light, striped with rosy pink.

Lion des Combats.—Ground colour white, segments flaked and striped with crimson. A superb flower.

Pardinum.—This is a very beautiful species from Peru. Flowers large, ground colour creamy yellow, dotted with reddish crimson.

Beauté sans Pareille.—Ground colour dark crimson, base greenish yellow, segments striped with white.

Princess Alexandra.—A superb, large, crimson flower, base green, segments striped with reddish purple.

Ackermannii pulcherrimum.—Ground colour rich deep crimson, beautifully veined with green.

Albertii flore-pleno.—Flowers bright orange, double. Introduced by an intimate friend of mine from Cuba.

William Pitt.—A superb variety, of good form; white, segments striped with rich vermilion.

Aurora.—Bright orange, segments striped with white. Very handsome.

Cleopatra.—A superb flower, large, and of good form; orange scarlet, streaked with crimson.

Calyptratum.—Flowers orange red, with light base.

Eldorado.—A fine, large, white flower, the segments striped with cerise, and shaded with purple.

Pyrrochroum.—A newly introduced species from Brazil. Flowers very fine, reddish scarlet in colour, base greenish yellow.

Striatum superbum.—Ground colour deep red, segments streaked with white and green.

Beauté sans Rival.—A superb large flower, ground colour rich orange, streaked and mottled with white.

—Experto Crede.

GRAFTING.

In the course of a few weeks the time will have arrived for grafting operations to be commenced. With us in this country the forms of the process of grafting are few and simple. We have first the ordinary whip-grafting, cleft-grafting, inarching, and budding. These are what are generally practised among us, with here and there a fanciful form introduced by some ingenious operator. The French are more elaborate and diffusive in this operation than we are. Whole treatises have been written on the subject, forming good-sized volumes, and among these the most recent are those by Abbé Dupuy and M. Charles Baltet. We had occasion not long ago to notice this work of M. Baltet, which is at once concise, full, and practical. In it we have every conceivable variety of the graft fully explained, and as M. Baltet had the kindness to furnish us with illustrations of the most important forms of grafting, we have much pleasure in laying them before our readers, with the descriptions taken from the original work.

Inarching (*Greffage par approche*) is the oldest of all. From time immemorial Nature has furnished examples of it in the forests and hedges, where it is met with in trees united by their roots or branches through being long in close contact and by continued friction. Inarching consists, then, in uniting two trees by their stems or their branches. In some cases it is a branch of a tree that will be grafted on to the tree itself. The time of inarching begins with the movement of the sap and finishes with it—from March to September. The stock and the graft may be either in the woody or herbaceous state; in whatever condition, the operation is the same. In inarching it is not necessary to remove the leaves from the graft, as in other systems, because the graft remains in conjunction with the parent tree when it is joined to the stock. A slice of the wood and bark is made on the stock and on the graft, the same in both, so that the two parts will fit and unite intimately. To facilitate the union a ligature and grafting-wax are applied; a stake is added if two distinct trees are to be dealt with.

After a year or less of growth, when the bond is complete, the graft is separated.

[There are five forms of inarching treated on by M. Baltet, some of which differ so slightly from each other that we consider it not worth while to illustrate the whole. The first is what he calls "*en placage*," and consists in merely removing a slice of bark and wood from the stock and graft respectively, and binding the naked surfaces close together by a ligature of bast, cotton, or wool, and protecting it either with grafting clay or wax. The second is what he calls "*en incrustation*." Two sloping cuts are made on the graft, so as to form an angle, and a corresponding angular cut is made into the stock to receive the scion, which, when bound together as described above, unites with the stock. The three following are so distinct we shall treat them separately.]

Inarching, the English way (*Greffe par approche à l'Anglaise*). —*Fig.* 1. Over and above the ligature the graft can be made still safer by making on the two naked surfaces where the bark has been removed a set of corresponding tongues (A and B),

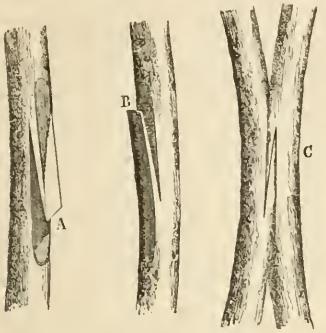

Fig. 1.

which are united as in c. If a slow union is dreaded the stock is headed-down at the time of inarching, and the graft applied on the top.

Buttress-inarching (*Greffage par approche en arc-boutant*). —Employed more especially for the restoration of plants, this mode of inarching is equally useful for propagation, and is practised from April till July. The chief difference between this and the preceding consists in heading-down the graft, tree, or branch, and introducing it under the bark of the stock. The graft being topped and cut slantingly, thin at the tip under the shoot or terminal branch, it is inoculated on to the stock by means of an incision—thus, ⊥, made in the bark. The position of the incision is regulated according to the length of the graft, but about three-quarters of an inch lower, in such a manner that, to introduce the graft it is slightly bent from above downwards to give it a returning motion; then slide it under the bark of the incision as if it should act like a buttress. The two principal modes of buttress-inarching are only applicable during spring and summer.

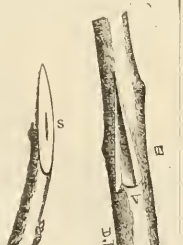

Fig. 2.

Buttress-inarching with a Bud (*Greffe en arc-boutant avec œil*).—*Fig.* 2. The bud being chosen as a terminal shoot, we cut the graft (s) in a flat slanting direction, and introduce it under the bark of the stock (T), where it has been raised (V).

Buttress-inarching with a Branch (*Greffe en arc-boutant avec rameau*).—*Fig.* 3. The graft (L) bearing an adventitious shoot will be shortened about three-quarters of an inch by a flat sloping cut (S) on the opposite side from the shoot; care must be taken to reduce the thickness of the slant, except at the point, and not to remove the leaves neither of the branch nor the graft. The stock is a distinct tree (O), bearing the graft-branch. The incision (P) is made in such a way as that the graft will be inserted as represented at R. The shoot (M) is preserved entire, or shortened to two eyes, according to its

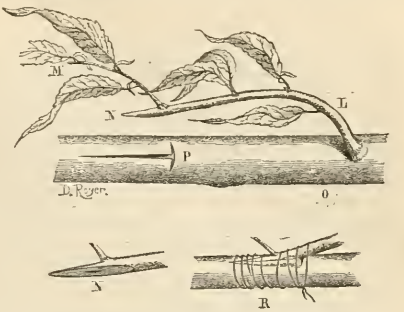

Fig. 3.

length. It is called an adventitious shoot if it is produced in the current year on an herbaceous graft-branch; then the grafting should have been done in summer. It is called young wood in the spring on the woody graft-branch, or the graft-branch of the preceding year. In that case the grafting should have been performed from April to June.

[Buttress-inarching is a safe and excellent mode of renewing defects in trained trees where the symmetry of the tree is an object of consideration with the cultivator. It not unfrequently happens that a tree of great beauty of form suffers by the loss of a branch either by the vicissitudes of the season or by accident; in such cases it is most desirable that some remedy should be available, and there is no better method of repairing such injuries than by this method of buttress-inarching.]—Baltet, *L'Art de Greffer*.

SUCCESSIONS OF VEGETABLES.—No. 6.

CAULIFLOWERS.

Early London.—A good early kind, with fine medium-sized heads, not very close, but white and good. Sow August 20th, February 15th, and March 6th in gentle heat; on March 15th under a south wall; April 6th and 26th, and May 20th.

Early Dwarf Mammoth, or Frogmore Forcing.—Sow August 20th; on February 15th and March 15th in gentle heat; on March 20th under a south wall; April 6th and 26th, and May 20th.

Early Dwarf Erfurt.—Plant dwarf and compact; heads large, white, compact, and excellent. Sow August 20th; March 15th in gentle heat; March 20th on a south border; April 6th and 26th, and May 20th.

Walcheren.—Heads large, not very close, but white and good. Sow August 20th; March 15th in gentle heat; April 6th and 26th, and May 20th.

Stadtholder.—Heads large, compact, and solid. Sow August 20th, April 6th and 26th, and May 20th.

Asiatic.—Very large close heads. Sow March 20th under a south wall; April 6th and 26th, and May 20th.

Lenormand's.—Large close heads. Sow March 20th under a south wall; April 6th and 26th, and May 20th.

Veitch's Autumn Giant.—Heads large, compact, firm, and white; distinct from all others, and a valuable acquisition. Sow August 20th, April 6th and 26th, and May 20th.

Here we have eight sorts, and all good. Four will be sufficient for most gardens, and those which I consider best are Early London, Walcheren, Stadtholder, and Veitch's Autumn Giant, and Early Dwarf Mammoth (Frogmore Forcing), for growing in pots in cool houses, also under hand-glasses. The most useful of all is Walcheren; by sowing it on August 20th, September 7th, February 15th, March 15th, in gentle heat; on March 20th under a south wall; and on April 6th, May 20th, and June 7th it affords a supply of good heads from the close of May to the January following. Indeed I have now in a south border plants each with a head the size of the closed hand, and these, if taken up, laid in a cool place, and protected from frost, keep good a month or six weeks. I am also persuaded a like result would be attained by frequent successional sowings of Veitch's Autumn Giant, a much superior variety; but I have a

liking for different sorts, and do not wish to confine myself to one, for though I have known a gardener who could not be induced to grow more than the never-failing Walcheren, I should be unwilling to resort to the retarding of the plants, &c., needed to keep up a succession between the August-sown and the spring-sown plants.

Now, at the August 20th sowing I consider it well to sow Early Dwarf Mammoth, or Frogmore Forcing, and Early London; the former to be potted early in October, and grown in a cool house with plenty of air and light. Place the plants first of all in 3-inch pots, and when these are full of roots, or early in January, shift into 6 or 7-inch pots. In these they may remain until March, or if the weather is severe until early in April, when they may be turned out in pits or under hand-glasses, and, if they could have the benefit of a gentle bottom heat, say 2 feet of tree leaves and dung, would produce fine heads in May or early in June, according to the weather, succeeding the late Broccoli. Instead of adopting this method, the plants early in October may be pricked off about 3 inches apart in frames or under hand-glasses, and be planted out on a warm exposure in March or April. Whether in frames or under hand-glasses, the plants cannot have too much air, but must be protected from frost, keeping them close and in the dark while they are frozen. In spring those under hand-glasses may be thinned-out to three or four, and the plants left should be earthed, have the lights or glasses raised on bricks as they grow, and be watered in dry weather. They will be the first to come in at the beginning of June, and will be followed by those planted out from the frames or hand-glasses.

At the August sowing sow also Walcheren and Veitch's Autumn Giant, so as to make sure of there being no break in the succession. They should be pricked-off in frames, and planted out in spring. These will come in at the end of June or early part in July, and with the Autumn Giant will keep up a supply until those sown in heat come in.

The plants raised in heat in spring should have a mild hot-bed, be only a few inches from the glass, and be kept cool at their tops. If at any great distance from the glass and in any great heat, they will all go off at the stem or "blackleg," and they are then useless. Prick them off when they show a pair of rough leaves, either in the same bed or in one equally cold, and keep them only gently growing. They should be planted out when large enough. The heads will come into use about the middle of July, and as we sow early and later kinds a continuous succession will be maintained.

The plants of the spring and early summer sowings should be pricked-off about 2 inches apart when large enough to handle, and be planted out when about 6 inches high, or with half a dozen leaves. It is a good plan to take them up and plant with a trowel, instead of pulling them up and planting with a dibble, as then they do not experience so great a check, and are not so liable to button. In dry weather they should have an abundance of water, and liquid manure should be poured between the rows once or twice a-week.

Of all the crops that from the May sowing is the most important, as it is that which affords the autumn supply. They should be planted out by the middle of July, and I put in a good breadth early in August to make sure of a late supply until the winter Broccoli comes in. From the first planting the heads are fit for use early in October, and to insure a lengthened supply a number of plants with close heads about half developed should be taken up, laid in earth in a sheltered place, and be covered with straw mats or other covering in severe weather. From the last planting we obtain heads in November, and later in mild weather, and the plants taken up and laid-in afford a supply until January, or afterwards if protected from frost. An open shed is an excellent place, but they should be covered with straw in severe weather.

The Cauliflower season may be said to commence early in June, and in the south in May, continuing until November or frost; and by taking up, laying-in, and affording protection it may be prolonged until January.

For small gardens, Early Dwarf Mammoth and Dwarf Erfurt are recommended, with Veitch's Autumn Giant for late use. It deserves a place in all gardens.

One ounce of seed of four of the kinds named is sufficient for a garden of two acres, with a packet of Autumn Giant additional; 2 ozs. for a garden of one acre, and so on in proportion downwards.

BROCCOLI.

Snow's Superb Winter White.—This is a very good sort. Sow at the end of March or early in April, and again on May 10th. The heads from the first sowing will come into use in December, and continue so until February; and the second sowing will be ready in January or February if the weather be mild.

*Backhouse's Winter White Protecting.—Heads large, white, and compact. It is earlier, hardier, and more self-protecting than Snow's, and is a most desirable kind. Sow it in the second or third week of March for heading in December, and again in the second week of April for heading in January and successionally.

Malta.—A dwarf-growing kind; heads medium-sized, compact, and white. Sow April 10th. It is in use early in March.

*Veitch's Spring White. — Dwarf and compact-growing, heads medium-sized, close, and white. Sow April 10th. It heads early in March.

Dilcock's Bride.—Of dwarf, compact growth; heads large, compact, and white. Sow April 10th. It heads at the end of March or beginning of April.

*Elletson's Surprise.—Of dwarf, compact growth, with large, close heads. Sow April 10th. It is in use in April and May.

Dalmeny Park May.—Dwarf, hardy; heads, large, close, and white. Sow April 10th. It comes in during May.

*Lauder's Superb Late Goschen.—Habit dwarf; heads large, close, and excellent. Sow April 10th. It comes into use about the middle of May, and heads until June.

I have omitted the Cape, Purple, &c., as I have found that with a supply of Cauliflowers in summer and autumn, and good close heads of Broccoli in winter, spring, and early in summer, they are not cared for, and, indeed, they only take up the room wanted for subjects in greater demand.

Half an ounce of each of the four kinds marked with an asterisk (*) are sufficient for a garden of two acres, and half that quantity for a garden of one acre; but to insure a supply it is necessary to grow the four kinds.

The soil for Broccolis should be in good heart, the situation open, and the distance between the plants ought not to be less than 2 feet, more if the land has been enriched with fresh dung. They should be planted out early in July, and, with the exception of the early-heading kinds, laid in or down at the end of October or beginning of November.—G. Abbey.

GLEICHENIA RUPESTRIS CULTURE.

A leisure half-hour, what shall I write about? I have so many favourites that I scarcely know which to select—I will decide to write a few lines on the successful growth of that beautiful Fern Gleichenia rupestris.

In taking a walk round the fernery just now my eyes lighted on my favourite, and the thought struck me that no lover of plants could look upon it without admiring it—not that it is a gigantic plant (it is 4 feet in diameter, by 2 feet high), but because of its perfect health and its exquisite foliage and growth. It forms a mass of beautiful light green fronds, hanging gracefully down over the pot in which it is growing.

The thought struck me when looking at and admiring this beautiful plant, How is it that we so rarely see Gleichenia rupestris exhibited by amateurs? Is it because of its costliness? No. What, then? Because of unsuccessful treatment and failure in its culture. For my own part I have never had the least difficulty in growing this beautiful Fern, as I have had before several plants as good as that referred to, and much larger specimens of some of the other species. Shall I say it is difficult to grow? No, quite the reverse; it grows, in common phrase, like a weed, and yet we do not see it generally exhibited or grown. I have no hesitation in saying that it is more through ignorance of its proper treatment than owing to the expense of the plant that we do not frequently see it grown and exhibited. I will state as plainly as I can my mode of treatment, and if it is instrumental in helping to success any fellow plant-lover who may have failed in growing this beautiful Fern, I shall feel myself amply repaid for my leisure half-hour's writing.

We will suppose that we have just purchased a healthy young plant from the nursery; to shift it at once would perhaps be hardly advisable, at least I should prefer to let it alone for a week or two after having it home, until it showed signs of fresh growth. Then prepare the soil; I have always found the following the best: two-thirds good fibrous peat, and one-third good, turfy, half rotted yellow loam, with a free admixture of silver sand, and small lumps of charcoal the size of a walnut, mixed well together. Prepare the pot by filling one-third of its depth with crocks, putting the larger crocks underneath, and a good quantity of small ones on the top; put over these a layer of sphagnum moss, or if this is not at hand a layer of the roughest of the soil; fill up with the compost, and place

the plant so that the crown or rhizomes may be about half an inch below the rim of the pot, fill in round them, and give the pot two or three smart taps on the potting-board or floor; afterwards press the soil firmly all over. Do not bury the rhizomes, but rather let them be close on the top of the soil. Let the surface be finished off rather smoothly, and the potting is done. I generally allow a liberal shift, so that the rhizomes may have room to run. The potting completed, place the plant in an airy part of an intermediate house; do not allow the sun to shine upon it, but let it have as much light as you can. Water it for the first three or four times with a fine-rosed watering pot, so that the soil may settle about the roots. All is now complete, and with a little care in its treatment you will soon have a beautiful plant.

I may add that I do not think any of the Gleichenias require half so much heat as many are accustomed to give them; in fact, some of them will thrive in a cool house, and be far more satisfactory than in too much heat.—T. B.

THE BENEDICTINE, EDGARLEY, AND ESPERINE PEARS.

I was very much surprised to see my name mentioned in a footnote in your Journal, respecting the Glastonbury Pear. I beg to say Mr. Sampson's statement with regard to my having raised it is incorrect. I certainly gave him the grafts and some of the fruit, at the same time telling him I believed it came from a wilding growing in an orchard hedge at the back of my garden. I should feel particularly obliged by your contradicting his statement as to its being raised from a cross between any particular Pears grown by me.—W. G. L. Lovell, *Montague Villa, Weston-super-Mare.*

As to the Edgarley Pear being identical with the Esperine I have strong doubts, and may say that I am almost certain that it is not—that is, if the trees sold to me by Mr. Sampson under the name Benedictine came originally from the Edgarley. But the parentage given by Mr. Sampson precludes this idea. Mr. Sampson gives the Princess of Wales as one parent and Van Mons as the other, a parentage of which I have grave doubts. Again, as to the Edgarley and Esperine being the same I have the same doubts, although Mr. Rivers says that Mr. Porch saw a Pear which he considered to be the same as the Edgarley at Mr. Young's nursery at Taunton, "and that, therefore, the Edgarley Pear is French, and the true Esperine." Perhaps Mr. Young obtained grafts from Edgarley before Mr. Porch knew the tree. Mr. Rivers's remarks would make us suppose that Mr. Porch obtained the tree at Taunton, but Mr. Porch's remarks go to prove the contrary. Again, the Esperine first fruited with Van Mons in 1824, or thereabouts, and could not well be planted at either Taunton or Edgarley until 1830, and then as a very young tree; it would now be about forty-two years old, and the oldest inhabitant must have a short memory if he cannot recollect so far back as forty years ago. In fact, I agree with the Editors that we are in a sort of fog about these Pears, and that the two cannot well be the same. I think Mr. Lovell, Mr. Sampson, and Mr. Porch, should combine to clear away the mist.—J. Scott.

P.S.—Is Mr. Lovell's tree a seedling, or was it grafted from the Edgarley one?

STORING CELERY.

I hear the question frequently asked, How to protect Celery from damping and rotting off? The system I have adopted this season has been most successful. At the end of November I took up two rows of Incomparable White, and stowed it away in a moderately damp cellar in sand. The last stick was used yesterday (January 26th), and was as fresh as the day on which it was taken up. At the end of December I took up two rows of Manchester Red, and treated it in a similar manner, the first stick of which was used to-day. It was equally good and crisp. I shall take up two more rows as soon as we have a couple of dry days in succession, and I have no doubt the Celery will be fresh and crisp in April, or later. I send you this information, believing that so simple a mode of preserving so useful an esculent is not generally known.—Henry Smith.

Sidney Seed-sower.—A larger and improved form has now been prepared by Mr. Cox, the inventor. The improvement is that the seed-sower now delivers freely, and without choking, wrinkled or square-sided Peas. There are other advantages also: the larger size is more useful in large gardens for all sized seeds, also for market gardeners and for farmers for filling-in blank places in fields.

NEW ŒNOTHERA.

As is their custom at the opening of the new year, our contemporaries of the horticultural press have in recent issues placed before their readers elaborate notices of our gains in the way of new plants, fruit, and vegetables during the past year—all very exhaustive, no doubt; but yet we looked in vain among their notes for any allusion to a charming novelty whose acquaintance we made last year, and which, we submit, has strong claims to be regarded as A1 among the cream of hardy flowering plants. We allude to a new dwarf Œnothera, from Utah, which we saw in flower at Glasnevin last year, and for the introduction of which, as of so many other choice plants, we are indebted to Dr. Moore. Calling at the gardens one evening last summer, while walking round with Dr. Moore, he asked, Had we seen the new Œnothera? Being answered in the negative, he led the way to the lock-up garden or sanctum, where one is sure at all times to meet something new, very rare, or of much botanical interest. On this occasion, however, all else was forgotten in admiration of the lovely little transatlantic gem to which Dr. Moore introduced us. Looked at in the quiet stillness and shadows of a summer evening's close, with its circlet of large pure white flowers, raised vertically above the foliage, on long, slender tubes, and expanding their broad fair bosom to the cooling moonbeams, this lovely plant presented an appearance altogether unique and striking.

This plant is altogether unique amongst its congeners as regards habit and appearance. The best of the latter, as, for instance, Œ. missourensis, Œ. Lamarckiana, &c., though showy as regards flowers, are of a gawky, straggling habit, which detracts much from their value. The plant to which we now direct attention is just the opposite, being single-stemmed, compact, and dwarf, flowering when not more than 6 inches high, and at the end of the season rarely doubling that height. But to come to particulars. The stem is short, stout, some 8 or 10 inches high; the leaves runcinate, having long foot-stalks, which, together with the midrib, in the lower leaves are white, in the upper red or pinkish. Commencing at the base, the flowers issue in long succession from the axils of the leaves, and are elevated vertically over remarkably slender tubes, fully a span in length, in a way to produce a beautiful effect. The flowers, as compared with the plant, are of great size, pure white, the limb of the corolla consisting of four very large obcordate petals, at the base of which the anthers are placed, round the mouth of the tube, which here expands considerably, and is of a greenish yellow colour. The stigma is cruciform and considerably exserted. The above description, we are quite aware, is very imperfect, and conveys a still more imperfect idea of this fine flower. As yet, as far as we are aware, this Œnothera is without a specific name. It comes from the state of Utah, North America, and was communicated to Dr. Moore by his friend M. Roezl, of Zurich. When we saw the plant at Glasnevin it promised to seed freely, and we hope ere long to see it widely distributed, and taking a prominent position in the choice herbaceous border, or cutting a figure in some phase of subtropical gardening, for which its dwarf habit and exotic appearance seem to render it eminently suitable.—(*Irish Farmers' Gazette.*)

COOL ORCHID CULTURE.

For some time I have had the opportunity of seeing the good results attending the cool treatment of Orchids, and I purpose offering a few remarks respecting it, which, doubtless, will at least interest some of our amateur cultivators. I need scarcely say that the yearly demand for cool-house Orchids is great and increasing, nor is this to be wondered at, for they are a lovely class of plants, and can be grown at a much less expense than the East Indian Orchids, besides being productive of more enjoyment to the cultivator and visitor.

The first matter to be taken into consideration is a house suitable to their requirements. This should be so constructed as to allow the plants to be as near the glass as possible, in order that they may have the full benefit of the light, the direct rays of the sun, of course, being at all times avoided by

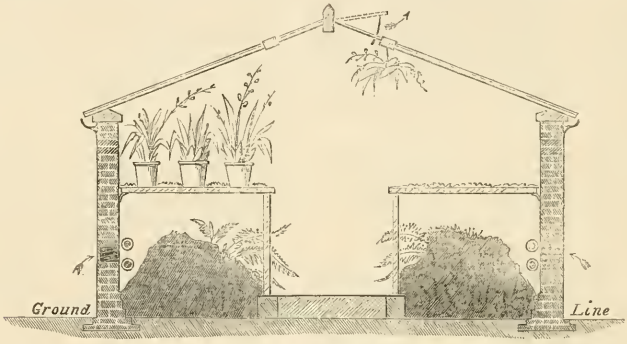
means of blinds. The accompanying figure is a section of the house here devoted entirely to their cultivation. It is about 60 feet long, 12 feet wide, and 7 feet 6 inches high in the centre. Only one flow and return pipe is used, that being sufficient to keep up the required temperature, which, to take that of winter, is a minimum of 40° and a maximum of 50°, or a mean winter temperature of 45°. During the summer no artificial heat is used, and air is admitted freely not only by day but at night. This, doubtless, is a much cooler temperature than that adopted by many; but as regards its being ample for practical purposes, I will allow your readers to judge for themselves by the following results.

In the first place must rank that magnificent Odontoglossum Bluntii; one of the stages is entirely filled with this, containing upwards of a hundred healthy and vigorous plants. Many of the bulbs measure 5 and 6 inches in circumference, while some are nearly as long. To see thirty or more spikes of this open at one time is a glorious sight, and such was the number produced by these plants during the past summer. As a proof of their free-flowering, I have taken from my note-book the following table of spikes that opened each month during the past year, which will confirm the statement made by Mr. Douglas at page 31, where he says, "They may be had in flower every month in the year."

January	4 spikes.	August	3 spikes.
February	5 ,,	September	7 ,,
March	3 ,,	October	5 ,,
April	1 ,,	November	5 ,,
May	16 ,,	December	3 ,,
June	39 ,,		
July	12 ,,	Total..	103

At the present time about thirty spikes are in an advancing state. These would average twelve flowers on a spike, many of the individual blooms measuring 4½ inches in diameter. The largest number of flowers on one spike was eighteen, although in three distinct cases single bulbs produced respectively twenty-two, twenty-four, and twenty-eight flowers, formed on two spikes. One particular plant of this lovely species has six leading growths; in 1870 the plant had but four bulbs, from which it last year produced six, and is now sending out six more, thus making twelve bulbs in two years. Such plants as these would soon form fine specimens.

In equal health are several plants of its relative, O. Pescatorei, of which an excellent variety has now twenty-five



Cool Orchid House at Fernichurst.

flowers on the spike; also O. cordatum, of which about thirty spikes are now in bloom, with from seven to nine flowers on a spike; as well as the splendid O. Hallii, of which we have three plants. One has produced seven spikes, the largest being nearly 4 feet long, bearing twenty-six flowers; total number on the whole, one hundred.

I may here remark that this plant has for some months been grown in a house a few degrees warmer, but, being the largest, of course it may reasonably be expected to produce more spikes. The strength, however, will be seen to be in favour of the cool house, for the next plant produced four spikes, the longest being 4 feet in length (from a bulb 6 inches long and as much round), bearing thirty flowers, while the whole number is eighty-eight. The other plant bids fair to follow closely, although it has not so many spikes.

In addition to the species I have mentioned there are several plants of Odontoglossum nebulosum with six and seven flowers on a spike, and many others, which would occupy too much space to particularise. I may remark that they are in equal health and vigour with the preceding.

Of Oncidiums, first stands that glorious O. macranthum, with bulbs 7 and 8 inches long, and nearly as much in circumference, surmounted by pairs of fresh green leaves from 15 to 18 inches long. One of these plants in the spring of 1871 produced a spike 12 feet long, bearing forty-four flowers, and at present it is throwing out a very promising spike. At one time last summer five plants produced one hundred flowers, which formed a splendid mass. No collection of cool-house Orchids should be without this, the most lovely of its class. A few others, such as O. cucullatum and nubigenum are in equal health.

Of Masdevallias, there is a good specimen of M. Veitchii, with sixty leaves from 7 to 9 inches long, and about an inch broad. This plant during the past few months has produced fifteen of its rich flowers; at one time it had six, when it presented a most magnificent appearance, while a plant of M. tovarensis has formed one of the most novel and interesting objects that has ever come under my notice. In 1870 it flowered with two spikes, one of which bore three flowers. Now, in general, as soon as the flowers have faded the scape is removed; in this case, however, the scapes were allowed to remain, and they did not, as one would imagine, die away, but this winter produced the one four flowers, and the other showed six, but only two of these were perfected. In addition the plant produced two more spikes: one in the usual manner bore two, the other three flowers, so that when fully developed it bore eleven flowers on four spikes. We see the Oncidium Papilio produce for years a succession of blooms in this manner, and Phalænopses will often form a lateral spike after the main stem has lost its beauty, but I never knew of Masdevallias doing so. Certainly it is no improvement to allow the plants to do so, for it must naturally impoverish them to a great extent. As well as the above, there is a healthy little piece of M. coccinea, with leaves more than twice as large as in those imported.

What a pity these mountain gems are so difficult to import from their cool homes on the New Grenadan and Peruvian Andes, where they grow at 10,000 or more feet above the level of the sea. We have forty or fifty species in books and herbaria, but how few comparatively have as yet found their way into our gardens!

In stating these results I must not forget the Disa grandiflora, which thrives admirably in this house, growing like a weed, and flowering with great freedom; last summer six small pans produced thirty-two spikes, making a grand display. I believe most of the inmates of this house have been grown there ever since they were imported, and consequently have never been subjected to a high temperature. We know that

plants of any description rarely thrive if suddenly removed from a high to a low temperature, or the contrary, yet at the same time many can be subjected to either with impunity if the heat is tolerably regular, and other circumstances, such as air and moisture, suitable.

To give some idea of the amount of moisture in this house, I may mention that the sphagnum on the surface of the pots is as moist and growing as freely as in its native swamps; in fact, it keeps us supplied for potting and other purposes, and it gives off a wholesome moisture, in which the plants seem to delight. In some places, also, the common Liverwort may be seen growing on the loose nodules of Cannel coal with which the slate benches are covered.

Most of the "cool Orchids," or those which come from high elevations, will endure any amount of water when making their growths, and should never be allowed to become thoroughly dry; for as they are often discovered close to rivers, waterfalls, and in similar places, and as some often send their roots into the water, to do so would be entirely contrary to nature.

With regard to air, when in their mountain homes they are constantly surrounded by fresh air freely circulating aronnd them, and when brought to our houses this should be admitted as freely as the external temperature will allow. Doubtless, if a little more attention were paid to this point, the result would be more healthy and robust plants, with leaves perfect to the points—a condition very pleasing to the eye of a good cultivator.

I may add, that in order to subject the plants as little as possible to the influence of fire heat, the house is protected by means of blinds at the approach of frost.—C. J. W., *The Gardens, Fernichurst.*

LILIES IN RUSSIA.

May I again ask Lily-growers in different parts of the country to give their experience of the cultivation of any sorts of Lilies which succeed well with them?

Since my last notes, page 33, I have received the following very interesting account of the growth of Lilies in Russia from my friend Mr. Wolkenstein, a distinguished horticulturist and Secretary of the Royal Russian Horticultural Society:—"I received your . . . . notes on the Lilies. I must tell you that we cultivate these bulbous plants successfully by placing them also amongst shrubby perennials, as Dielytra spectabilis, Spiræas, &c., or near the groups of woody shrubs, shadowed from the hot spring sun. We bury the bulbs 6 or 8 inches deep in the soil, laying under the bulb some sandy porous earth, and covering it with the same compound. In this way we have, in spite of severe winter frosts, every spring and summer well-flowering Lilies of the following species that are quite hardy with us: Avenaceum, bulbiferum, canadense, candidum, chalcedonicum, croceum, longiflorum, Martagon, Maximowiczii, pulchellum [qy. our Buschianum?] pyrenaicum, speciosum, spectabile, superbum, Szovitsianum, tenuifolium, testaceum, and tigrinum. As to the dung, the custom with us is to renew the ground every four or five years by adding a sufficient quantity of well-decomposed cow manure, and digging the ground well."—George F. Wilson.

STRAWBERRY PLANTING.

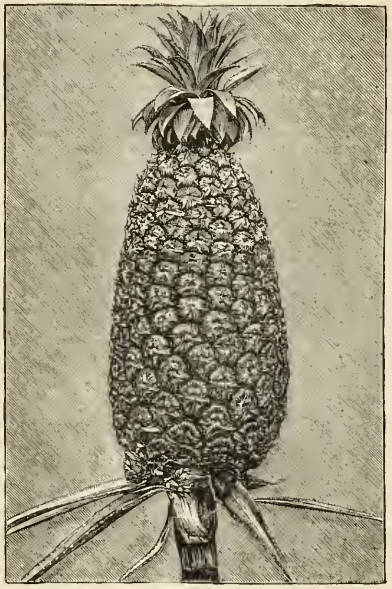
Persons who find it difficult to obtain a good crop of fruit from plants a year old may try the following plan:—To prepare plants for transplanting, a piece of ground should be selected, say 8 feet by 7 (this will plant a bed 45 feet by 9); take off the top soil to the depth of 4 inches, then have the piece covered with turf 9 inches wide, grass side downwards, replace the top soil, and plant at 9 inches apart each way. The following autumn the plants will have large crowns with strong healthy foliage. A month before transplanting cut the turf across, so as to allow each plant to have a piece of turf 9 inches by 9. The plants should not be allowed to bear fruit in the nursery bed. By the above mode a large crop may be expected the following year.

It is rather late in the season to try this plan. I should have drawn attention to it before had I not been detained in Italy several weeks longer than I had intended.—Observer.

The Royal Horticultural Society's Birmingham Show.—Messrs. Sutton & Sons have announced their intention to offer at the Royal Horticultural Meeting at Birmingham, in June next, £5 5s. for the best six dishes of Peas, half a peck of each sort, to include Dr. Maclean's Best of All, and £2 2s. for the second best ditto, also £5 5s. for the best three brace of Cucumbers, including Marquis of Lorne, and £2 2s. for the second best ditto. The competition is to be confined to noblemen's and gentlemen's gardeners.

SEEDLING PINE APPLE RAISED AT LAMBTON.

In our November issue we referred to what we considered a most promising seedling Pine Apple which we saw growing at Lambton Castle. Since then Mr. Hunter has favoured us with a photograph of a fruit of it. The plant from which the fruit



in question was cut was nearly nineteen months old. The fruit measured 12 inches in height by 20 inches in circumference, and weighed over 10 lbs. Its colour is a high orange, the scales on the bottom sides of the pips being nearly red. Including the crown, the height over all did not exceed 30 inches. In growth it is more robust than the Smooth Cayenne, and in habit less spreading; and, from its very free-fruiting qualities, it sometimes ripens its fruit before it attains the height of a Queen. Mr. Hunter informs us that he cut the fruit from which our engraving has been taken after it had been in the fruit room for three weeks, and found it quite fresh and free from speck or discoloration. One of the fruit recently ripened from a plant which twelve months and eleven days before was a moderate-sized rootless sucker, weighed 7 lbs. 10 ozs.; and another now swelling—December 9th—on a plant potted a rootless sucker last March, is 10 inches high by 16 inches in circumference, and will be ripe in ten months from the time it was potted. All have been grown in the Durham 11-inch pots, which are a small size, owing to the extent they taper to the base. The foliage is very distinct, being clad with very strong prickles set wider apart than any Pine we know. From the above qualities, in conjunction with that of its being more juicy and better-flavoured than any other large-growing Pine in cultivation, this variety must prove a very great acquisition in all collections of Pine Apples.—(*The Gardener.*)

[We are indebted to the courtesy of the Messrs. Blackwood for the above representation of this Pine Apple, which, with

the descriptive remarks, appeared in the January number of "The Gardener." Mr. Hunter informs us that from a plant nine months and thirteen days old he cut a fruit weighing 5 lbs. 13 ozs., finely formed, high-coloured, and with the pips evenly swollen.—EDS.]

THE GROS COLMAN GRAPE.

M. VIBERT, then residing at Angers, sent me this Grape some twenty years since. It bore abundantly with me, but did not ripen its fruit, being in a cold house. I have since seen it in fine perfection with Mr. Miller, of Bishop Stortford. Its berries were so fine in size and colour as to command a high price, making 9*s.* a-pound, while Black Hamburgh and Muscat of Alexandria made 7*s.* a-pound. Fully ripe its flavour is very rich, but when not so its flavour is not good; it keeps well, and requires to be "dead ripe." I send three or four berries; they were ripe in July. It seems as if it would be valuable as a market Grape from its large size, fine colour, and keeping quality.—THOS. RIVERS.

[The Gros Colman has now been grown for some years in many gardens with varied success. In some places it colours badly, its substance is hard and fleshy, and its flavour is that of a Grape, and nothing more. The fruit Mr. Rivers has sent is jet black, the substance tender and melting as a Black Hamburgh, and the flavour richer than that of any late black Grape we know.]

PRIMULA JAPONICA.

THINKING that it will interest your readers to learn something of the habit and growth of this magnificent Primula, we forward you a few extracts from letters received from Mr. Kramer, of Yokohama, Japan, who has at various times forwarded to us seeds and plants of this species.

He writes as follows:—"If the drawings in the European periodicals are true, Primula japonica must be very much finer at home than it ever is seen here. A cold climate and good cultivation have no doubt great influence, for its native country is said to be the island of Yeza. It is generally found growing on the banks of streams and watercourses in yellow loam. I have seen it growing from 2½ to 3 feet high with six or seven tiers of flowers—a magnificent sight.

"In sowing the seed it is very important to know, that as this Primula is not a native of a warm country, it requires no artificial heat for germinating, and that frequently the seed does not germinate until next spring, in fact the latter is the rule. I would, therefore, advise that the seed should be sown immediately, and left for at least six months undisturbed." (June, 1870).—"I have now some boxes which have stood for two years, and this year there are more plants coming up than even the first year" (May, 1871).

From this it appears that the seed takes a long time to germinate.

A moist yellow loam is best suited to the plant, and it is likely to improve much under cultivation. It will also prove especially valuable for hybridisation on account of its tendency to vary.—TEUTSCHEL & Co., *Colchester*.

MADRESFIELD COURT GRAPE.

I HAVE with a friend of mine to-day (January 23rd) cut the last bunch of this variety, and from what I now see it has fully borne out the character given to it by the Royal Horticultural Society. S. Simpson, Esq., of Manchester, a very good judge of Grapes, assured me a few days ago that a bunch I gave him, after hanging in a dry place, but still moderate in temperature, was kept five or six weeks amongst other thin-skinned varieties, and at the end could not be surpassed in flavour. I have it very fine in colour, with large berries. I am very sorry that I have not more of it on account of its excellent quality. I am devoting a house, about 40 feet by 18 feet, to its cultivation. The constitution is good, and I have no hesitation in saying it is a very desirable variety to grow.—JOSEPH MEREDITH, *The Vineyard, Garston, Liverpool*.

HORTICULTURAL CONGRESS AT BIRMINGHAM.—We are requested to announce that the Birmingham Local Committee, in connection with the Royal Horticultural Society's visit in June next, intend that there shall be a Congress during the show week, the details of which will be published as soon as they have been decided upon. The arrangements will, we believe, take something like this form: On Tuesday, June 25th, there will be a public dinner; on the following three days, Wednesday, Thursday, and Friday, a luncheon at a convenient hour and at a very moderate figure; and afterwards each day, as per a programme to be issued in due course, papers will be read, to be followed by discussions upon them. With a view to enable the Committee to make suitable arrangements, it is requested that all who are interested in the success of the Congress, and who have suggestions to offer, and all who are willing to read papers and take part in the Congress, will at once communicate with the Hon. Secretary, Mr. E. W. Badger, *Midland Counties Herald* Office, Birmingham. In the case of those who wish to read papers, it is desirable that they should state the subject of them, and the length of time they desire to occupy. These communications will be laid before the Sub-Committee, whose special business it will be to arrange for visitors, the dinner and luncheons, and the Congress. Early communications will be much appreciated.

IRON IN SOIL FOR ROSES.

THE question raised in your Journal by a correspondent on the effect of iron upon Roses and other plants is one of very great interest. I have not yet had a lengthened experience of the results of manures on Roses, but, like most of those who have studied the subject of manurial agents scientifically, I do not yet believe in the plant differing very materially from most others in its food-requirements. One general theory taught is, of course, that only those elements which enter into the composition of the plant are valuable as manures, and there is no proof, or well-sustained attempt to prove as yet, any agent is of use as a tonic or stimulant which does not feed the plant, or, like lime, make soluble or decompose the valuable matter in the soil. I do not allude here to the mechanical effect of soil materials, as this is to a great extent distinct. Some plants, of course, will put up with a poorer soil, and others, which are often called gross feeders, &c., will take more food from the soil, and particularly food of a nitrogenous character.

From general testimony it seems as if the Rose belonged to this class of plants, but I should like to see a trial of the experiment of growing Roses in a rich mineral soil against those treated with ammonial manure. It must be remembered, however, that we do not grow this plant for its seed, like Wheat, but for the leaves and flowers. I must confess being sceptical as to these strong shoots on your correspondent's Roses being sent up by the iron.

Iron does occur to the extent of a trace among the constituents of most plants, but hardly seems a necessity, and it is present in nearly every soil in more or less abundance. Its useful chemical effect on the soil would be difficult to see, the oxide being a very mild base—not to be compared in this respect with lime. As an indicator of the condition of soils by colour it is well known, and, doubtless, may have some effect on that of plants, both leaves and flowers. In some combinations it is considered most injurious, and your readers, unless indifferent to the loss of their plants, must be careful in applying it.

It almost makes one smile to see the various nostrums recommended by a "hundred doctors" to achieve great results. One vaunts soot, another malt sweepings, a third nitrate of soda, a fourth sulphate of ammonia, and another guano, believing them all to have a totally different result, whereas all simply depend, or nearly, on some form of nitrogen for their efficacy.

I was also somewhat amused to think of some of the readers of a contemporary being induced by an article from a distinguished florist carefully to collect all the hoof-parings from the farrier's, as being the very best manure for Roses; failing to obtain which, strange to say, bones were to be substituted, but on what principle it would be difficult to say, except their being equally parts of an animal. The former had one recommendation—it was a lasting manure. No doubt it would be; I hope their patience would be equally so. About as well make a man sit looking at his breakfast until dinner-time, and praise the lasting qualities of the food.

At a future time I should like to say a few more words on this subject if your readers would care to see them, but enough for the present. I would conclude by saying I do not wish to have given the impression that experiments of all kinds should not be persevered in, but a little more knowledge among hor-

ticulturists of accepted and well-grounded facts must be desirable and beneficial.—J. S. K.

BROCKWORTH PARK PEAR.

I WILL give you the particulars. In the year 1855 I advised my most intimate friend to buy an estate in the parish of Brockworth, and also promised to put it and all the buildings in good order. To do this I found it advisable on the largest farm to take down the house and all the farm buildings, and I erected new in the most convenient place. When the place was nearly finished a gentleman took it. About the beginning of March, when I was laying out the garden, my intention was to order the trees from you the following autumn, but he was so very anxious to have them at once that he prevailed on me to give him a list of what I meant to plant, and he fetched them at once from Cheltenham. I warned him of the consequences, and told him the probability was that he would get anything but what he ordered, which proved to be true. The tree in question was planted for Winter Nelis against a wall with a south-east aspect. I saw at once it was wrong; it bore three Pears the following year, and one was sent to me. I found it a very good Pear, and had a scion from it for myself; of course I consulted "Hogg" and came to the conclusion it was White Doyenné with a great many aliases. Since then I have let the farm to another person and he sent the Pears to Wheeler.—(*Extract of a letter from A. Bubb, Esq., to Mr. Rivers.*)

SANDRINGHAM HOUSE.—No. 2.

IN resuming our remarks on the fruit and kitchen garden we will first take the planting of the walls, of which the construction has been already described. Of the main south-aspect wall more than one-third the length is covered with glass; the remainder is planted with Peaches, Nectarines, and Apricots, with a few Pears. The Peaches consist of such standard kinds as Grosse Mignonne, Bellegarde, Barrington, Late Admirable, and Walburton Admirable, and of each there are several trees; and among the Apricots are several trees of the Moorpark, Hemskerk, Royal, Kaisha, and Musch Musch, the last two excellent for preserving. The south side of the wall running parallel to that just noticed, but on the other side of the garden, is planted with Peach, Apricot, and Pear trees; its north aspect with Black Circassian, Bigarreau, May Duke, and Morello Cherries, and with Plums. Pears and Plums cover the east and west aspects of the other two walls, and consist of admirably trained trees of varieties of established reputation for excellence, selected with the view to successive ripening; indeed throughout, whether against the walls or in the rows across the vegetable quarters, the number of trees planted has been in proportion to the keeping qualities of the fruit.

Mr. Carmichael says that his Peach trees on the open walls never fail to produce a crop with no other protection, even in spring, than the fixed coping; and he considers that, in his locality at least, no matter how unfavourable the subsoil, they will do so provided the trees are kept free from insects, and, in the case of their being in a stiff or clayey subsoil, lifted every two years in order to bring the roots more under the influence of the sun's heat. To keep the trees free of insects they are dusted when the flowers have set, or as soon as any green fly is perceived, with a mixture of one part of snuff and two parts sulphur. The absence of insect-curled leaves contributes to the ripening of the wood, and to promote this also, after cutting off the half of every leaf shading the fruit when it is swelling, all the leaves are cut in half after the crop is gathered. Mr. Carmichael, like many others, is no advocate for wiring the walls out of doors, considering that the trees succeed better against the brickwork trained in the old-fashioned way with nails and shreds. Of the medicated shreds introduced some time ago he speaks highly on the score of durability and convenience. It must be added that all the shoots of the Peach trees are loosened from the wall during the winter, only the main branches being kept nailed-in, and harder, better ripened wood it would be difficult to find. In the forcing houses the trees are all painted, as soon as pruned, with fresh-slaked lime and water, and this coating is left till it disappears in course of time, leaving the bark clean, bright, and insectless. The Gooseberry and Currant bushes are dusted with lime if insects or mildew appear; lime, in fact, is considered the best remedy for all insects which appear, and if one might judge by their fewness it must be an effectual one indeed.

Among the kitchen-garden crops Sea-kale holds a prominent position, great quantities being daily required, and the extent of ground cropped with it alone is as large as a moderate-sized kitchen garden. The ground is planted in rows 5 feet apart, and the plants are 18 inches from each other in the row. As soon as the leaves fall in autumn each crown is marked with a stick and covered 8 inches deep with fine soil taken from the spaces between the rows. The ground is thus thrown into beds 2 feet wide, and 3-feet alleys. Some of the latter are filled in November with littery dung, and the beds are likewise covered with the same material. A fresh bed is covered up every eight days so as to keep up a succession, and after taking the crop the crowns are left exposed; only four or five shoots are allowed to grow, and in this way not only do the plants remain many years without renewal, but the quality of the produce is excellent. It must, however, be remembered that the soil is light and friable, and probably if the same practice were adopted on ground of a retentive nature the shoots would not be so large as where covering with pots is resorted to. Asparagus is also grown extensively, there being no less than an acre and a half occupied with it. The whole is grown in single rows 3 feet apart. Mr. Carmichael advocates making the beds 6 feet deep, filling up with turf and rich manure, and staking the grass; in this way shoots of the largest size are obtained. A fresh bed is sown every year, and transplanted in the following year.

Among the other vegetables may be noted large breadths of Broccoli, Cauliflowers, and Lettuces, of which the Stansted Park is a great favourite. In Celery, Sandringham White is grown almost exclusively, being that most esteemed at table on account of its crispness, and in the garden from its not being liable to run to seed.

We will now look into the forcing houses, which extend about 320 feet along the main south-aspect wall. They were erected by Mr. Gray, of Chelsea, and, without presenting much ornamentation, are well designed for their several purposes and exceedingly substantial. All the houses are 50 feet long, but of varying height and width, each increasing 2 feet in height and 2 feet in width as we pass from the ends to the centre. Entering at the west end, first there is the early Peach house 14 feet wide, 14 feet high at back, with 2 feet of brickwork and 2 feet of glass in front. This is heated by three flows and one return, and the sashes at back are opened simultaneously by a cog-wheel and lever, and the front sashes push out by lever power. The same means are adopted in all the other houses. The trellis is about 20 inches from the glass, and is formed of iron uprights let into stone blocks, between which are stretched light iron rods at 8 inches apart. The trees in this house, which were all in blossom, are Elruge and Murrey Nectarines, and Bellegarde and Stirling Castle Peaches. The last, Mr. Carmichael considers the best Peach for forcing to ripen in the first week of May. Next comes the earliest vinery, heated by four flows and two returns. It is planted chiefly with the Black Hamburgh. The late house, similarly heated, is the next in succession, and contains such as Lady Downe's and Alicante. Then follows the second vinery, in which the Black Hamburgh is the principal kind. These two houses are the centre of the range, and 18 feet high at back, and the same in width. Next comes the Muscat house, at present occupied with bedding plants, and finally the second Peach house. In the vineries, of which the borders are partly inside, partly out, the Vines are planted, one under each rafter and one in the intermediate space. It will thus be seen that the rods are rather close together, and instead of allowing them to extend rapidly Mr. Carmichael only retains a limited amount of stout well-ripened wood at the ends of the rods, in order to have the lower eyes strong and fruitful as well as those nearer the top.

The Pineries are the next important structures. There are three half-spans of 100 feet long by 20, 18, and 16 feet wide respectively, and in the same range are Cucumber and Melon, and Strawberry houses. The varieties chiefly grown for winter are Smooth-leaved Cayenne and Black Jamaica, and for summer the Queen. Of these there was a fine stock both of fruiting and succession plants, nearly all of them planted out, and a number of suckers in pots. In point of vigour and cleanliness there was nothing left to desire—no sign of mealy bug, scale, or insect of any kind; partly, no doubt, owing to careful supervision, and partly also to the plants not being confined to pots, but having their natural freedom as regards the roots. Under the beds in which these are growing, chambers have been formed by resting larch battens upon bricks-on-bed, and on the battens a paving of bricks touching each other at the edges is laid, then leaves and soil. In these and other houses

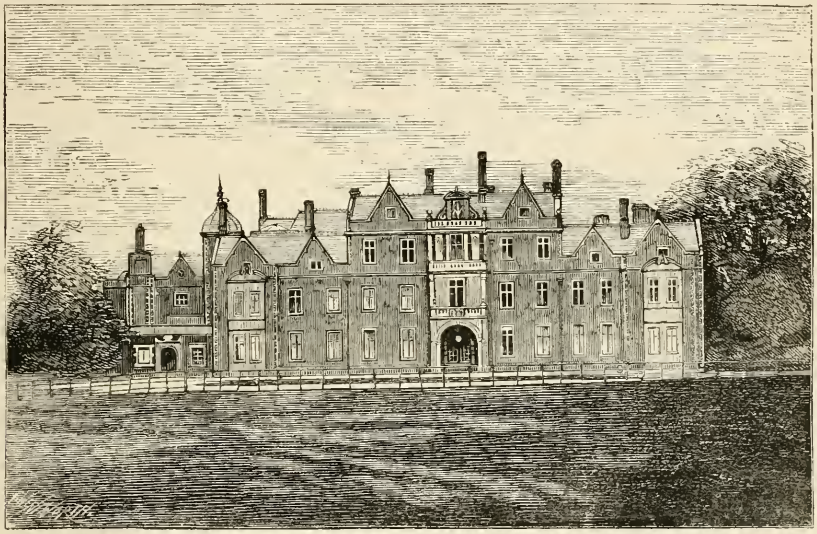
provision is made for securing a supply of water of the same temperature as the house by a tank in front under the iron grating which serves as a path.

In front of one of these houses is a sunk pit for forcing Strawberries, with which, in fact, the shelves of nearly every house are filled. To give an idea of the demand for this fruit we may state that no less than 10,000 pots are required to keep up an adequate supply, and that gathering begins on the 14th of February. For the earliest gatherings 5-inch pots are used; for plants to fruit in April and May sometimes 8-inch pots are employed. The runners to furnish these plants are all layered in small pots, for each of which a hole is made with a crowbar, and the pot pressed down; a stone is put on to keep the runner steady, and as soon as rooted the plants are shifted into 5-inch pots and placed on an open piece of ground fully exposed to the sun, ranging them in 4-feet beds with 2-feet alleys between. In the first week of October the plants intended to be first forced are laid on their sides, and the rest are all plunged in a border to the rims of the pots. There they remain without any protection till required for forcing. Every week a fresh



Sandringham House—East Front.

lot of plants are removed to the pit, which is filled with leaves, and further heated by a hot-water pipe. When the fruit begins to swell Mr. Carmichael puts a little of Standen's manure on the surface of the soil, and as soon as the bloom is set the fruit is thinned out so as to leave from twelve to eighteen to each pot. The extent to which the different varieties are grown for forcing is British Queen, 2000; President, 2000; Eclipse, 1000; Sir J. Paxton, 1000; Premier, 500; La Constante, 500; and the remainder consists of Dr. Hogg, President, Cockscomb, and some other varieties. The last lot generally flowers out of doors, and is only brought in if likely to be needed to keep up the succession till the out-door crops come in.

Peas, likewise, are forced in quantities, and for this purpose Maclean's Little Gem is alone employed. This is sown at the end of August in 8-inch pots filled with soil (which is pressed down) to three-fourths of their depth, eight Peas being placed round the sides. The pots remain out of doors as long as the weather is mild, but before frost they are placed in a temperature of 45° to 50° at night. This sowing begins to produce in the first week of December, the plants bear successively till February, and are succeeded by a sowing made about the end of September. The plants we saw were not only furnished with an abundance of their little pods, but were even ornamental by their blossom. There are so few who are not lovers of Peas, even when these are in abundance, let alone a rarity, that we have thought the method by which Mr. Carmichael produces them, and not in small quantities, is worthy of description and imitation. Green Peas in December and January are a rarity to be sighed after by many, but rarely obtained; but as Mr. Carmichael manages them there seems to be little difficulty about it, and yet we all know that the Pea will not bear forcing. The Kidney Bean, on the contrary, is well known as one of the easiest things to force, and of it, of course, in a place like Sandringham there was no lack. Cucumbers and Melons receive their share of attention, and of the former there were numbers hanging from the trellis ready for being cut. In one of the Pine pits Musa Cavendishii was throwing out a cluster of fruit which is likely to prove of great weight; and near it was the Mangosteen, which Mr. Carmichael hopes some day to fruit, but the plant is young as yet, and so far as we know it has only once borne fruit in this country.

Before quitting the kitchen garden the Mushroom house must be noticed, not only on account of its size but the fine crops it contained. This is 80 feet long by 15 feet wide, there being a 5-feet path up the centre, and on each side 5-feet shelves, three tiers at the back, two tiers in front, for the house is a lean-to against the north wall of the garden. The sides of the beds are of iron, with iron cross-bars, and the flooring is wood laid longitudinally from cross-bar to cross-bar. It is heated by a flow and return pipe, with evaporation troughs under the centre of the iron-grated pathway. On the same side of the wall are the fruit-room, which is large and well-fitted up,

potting, packing, and tool sheds, gardener's rooms, and underneath spacious root-cellars.

The plant houses are not large, and are chiefly filled with subjects suitable for in-door decoration, such as Poinsettias, Adiantums and other Ferns, Chinese Primroses, Cyclamens, Geraniums, Gardenias, which are great favourites for the button-hole, Begonias, fine-foliaged plants, and Azaleas.

In the pleasure grounds much has been done and much is still to be done. One great improvement is a new drive up to the east or main front of the house (of this we give a view taken by Mr. Pridgeon, of Lynn); formerly the drive led past the offices, and in unpleasant proximity to them, but now by a graceful curve they have a wide berth, and the approach is more in accordance with the dignity of the house, and will be still more so when the Deodars at the sides among the Laurels shall have attained a greater height. It is, however, on the west front that the principal alterations have been made, and the most important of these is the new flower garden which is represented on page 101. The beds of this are slightly raised above the rest of the surface, the outer edge of the soil forming a miniature ramp as practised by Mr. Gibson, in Hyde Park, and this is surrounded by various evergreens. The interior at present is filled with autumn-sown annuals and plants for spring flowering, and already, though the ground was only laid out last autumn, the appearance is very ornamental, and it will be much more so in summer. The evergreens round the beds of themselves give an aspect of life even in winter. The length of this panel, of which one-half is represented in the engraving, is within the walks 192 feet, its breadth 60 feet. On the same front, but nearer the house, there is a small garden on gravel with Box-edged beds, and beyond the larger new flower garden a neatly laid-out bulb garden, of which the effect from the terrace walk in front of the mansion is no doubt good when the bulbs and other plants are in flower.

A few more notes on the pleasure ground and we have done. There are many pretty views from the terrace on the west front, over the flower gardens just noticed, especially towards the church, of which more than one view is obtained; and the simple tomb of the young Prince of a day, so well depicted in *The Graphic* two or three weeks ago, can be seen from a point near the south-west end of the terrace walk.

The park and pleasure grounds are not so extensive as those attached to many country mansions, extending only to about 120 acres; in the pleasure grounds Deodars, Picea nobilis, and a considerable variety of Conifers have been introduced with excellent effect, and on each side of one walk is an avenue of various species of these planted by distinguished visitors as mementos of their visits. The old lake, merely a pond, has been abolished, and a new one formed, indeed, re-formed as well, for since it was made the depth throughout has been reduced to 4 feet as a safeguard against accidents on the ice. The rockwork about it is well executed in the carr stone of the neighbourhood, we believe by Mr. Pulham, of Broxbourne, who also constructed a boat-house or boat-cavern, which has been highly approved of.

The park is well wooded, but contains no trees remarkable for great age and size; there is, however, an avenue of fine Limes leading from the Norwich gates to the house. Great improvements have been effected in remaking walks, in planting trees and shrubs in all parts of the grounds; and the energy with which all this has been carried out and the good immediate effects produced are highly creditable to Mr. Carmichael, whose courtesy in explaining all works connected with the garden no one who has had the pleasure of visiting it can fail to appreciate most highly.

Mowing Machines.—We warn our readers from employing tinkers or any but the makers of the mowing machine or one of their agents to repair it. It is unfair to the makers, and mistaken economy in the purchaser. We have known instances when the tinkered machines would not mow, and the owners blamed the makers!

DEATH OF MR. THOMAS OSBORN.

It is with the greatest regret that we have to announce the sudden death of Mr. Thomas Osborn, of the Fulham Nurseries, on the 28th ult., at the age of 53. Mr. Osborn was one of the two sons of the late Mr. Robert Osborn, whose death we noticed a few years ago, at a very advanced age, and like his father was a man whom to know was to respect and to admire. He was a thorough gentleman in the best sense of that word, and he will leave a great blank behind him among those with whom he was so long associated in the world of horticulture. Mr. Osborn was present at the last meeting of the Royal Horticultural Society, apparently in the enjoyment of his usual health, and took part in the proceedings of the day; and we feel assured that the intelligence of his premature death will have a saddening effect on the numerous friends he has left behind.

MRS. PINCE'S MUSCAT GRAPE.

Notwithstanding all that has been said against this Grape, it is evident that it begins to be a great favourite with many. For my own part I consider it the very best late variety in cultivation, and I have no hesitation in saying that I believe it will be, when its culture and merits become better known, the most popular late variety in every garden establishment.

I say culture, as I think there is something in this that has been misunderstood, and so has caused disappointment, consequently bringing much abuse on this good variety. It is well known that most of our best Grapes require some special treatment to bring them up to that standard of perfection so prized by all good Grape-growers; neither is Mrs. Pince's Muscat an exception to this rule, and if growers were to give their experience for and against, doubtless the special requirements of this variety would be elicited, for, as Mr. Pearson justly states at page 17, a man may miss his way in the cultivation of a new kind of fruit without being exactly a fool.

With your permission I will state my experience. In my previous situation I received some of the first Vines of Mrs. Pince that were sent out. There were at that time, and still are, various opinions with respect to the right place to plant this variety; some advocated for it the heat to which Muscat houses are in general kept, others cool treatment, if I may so term it. I planted a Vine of it in the Muscat house; also one in a comparatively cold house. The border in both instances was well prepared, and the Vines received the same treatment as regards pruning, &c. Perhaps I ought to state they were not allowed to carry any fruit the first season. The following season they broke freely and very strongly, showing an abundance of bunches, which were reduced to the required number.

The Vine in the Muscat house showed the largest bunches in the embryo state, in fact throughout; in both instances they were all that could be desired with regard to setting. In the Muscat house the berries swelled off evenly and to a large size, but the somewhat drier atmosphere and the extra amount of light which was admitted by lateral pruning, and which give a good finish to the Muscat of Alexandria, failed to do the same with Mrs. Pince's Black Muscat, and the colour of the latter as grown under the circumstances may be described as dingy red, although in bunch and berry it was everything that could be desired.

In the cold house the berries swelled evenly at first, but many of them after attaining the size of Peas remained stationary, which fault often destroyed the appearance of the bunches; notwithstanding, the Vine finished off a fair proportion of good-sized bunches, the berries of a medium size, with a deep bloom, and as black as Sloes. The flavour of this variety is generally acknowledged to be good. In my opinion it improves like that good variety Lady Downe's by being allowed to hang, and the flavour does not arrive at its best until after Christmas when the Grapes are grown for late use. My experience with Mrs. Pince's leads me to believe that to grow it to perfection it requires a house devoted to its culture, similar treatment to that generally given to Muscats until the ripening process commences, when a cool moist atmosphere should be maintained with an abundance of air; I would even advocate a little shade during bright weather. If these points are attended to, with the culture generally given to the Grape Vine by skilful cultivators, I have no doubt but this variety will produce bunches and berries of such a size, with a deep bloom, as black as Sloes, a rich agreeable flavour, and such good keeping qualities, that it cannot be equalled by any Grape in cultivation. I have drawn this conclusion not only from my own experience with it, but from what I have seen of it when it was growing in the Exeter nursery previous to its being sent out, and from what I have seen of it since in several good gardening establishments.—Thomas Foote, *Gardener to Sir A. F. Elton, Bart., Clevedon Court, Somerset.*

Barometrical Fall.—My barometer to-day (24th ult.) was 28.24° ins. in the morning—lower by 0.16 than I ever registered

before. I have been expecting a gale all day, but it has evidently been on the south-west of Ireland or somewhere thereabouts.—C. P. Peach, *Appleton-le-Street*.

[The barometer at Pimlico, near London, was 28.35 ins. at the same time.—Eds.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the season has been so mild it has been difficult to wheel manure on the ground; as soon, therefore, as the ground is fit, let this work be forwarded as much as possible for all spring crops. Where dung will have to lie on the surface until March, it should be soiled over immediately, or drying winds will steal away its beneficial properties. Spring *Broccoli*, such as Grange's or Knight's, now coming in should be protected. Push a handful of soft hay amongst the leaves. Sow a little *Celery*, *Cauliflower*, and *Lettuce* seed in heat. If the early *Peas* appear above ground throw over them a handful of sawdust in a ridge, but this must be removed when their leaves are expanded.

FRUIT GARDEN.

As soon as the blossom buds of Apricots can be distinguished, the trees should be pruned, and nailing completed. The eggs of the caterpillar which so much infests the leaf should be hunted for and destroyed; they are deposited on the branches in circular groups, of about the size of a Parsnip seed, look somewhat like it, and have the appearance of being pasted on. The trees must have protection forthwith. Take care to secure bundles of the main twigs of Apple prunings, tie them at each end, and put them in some dry place; they are very useful in summer. Prune and nail Peaches and Nectarines; as soon as they have been nailed, soak the trees and wall with soapsuds, and when dry take a bowl of sulphur mixture (sulphur blended with softsoap water until as thick as paint or nearly so), and draw a strip with the brush between every two shoots. This is a good preventive of red spider. Look after Gooseberry buds; country folks in some places tie feathers over the bushes to keep birds away. In wet weather prepare shreds for nailing, make tallies, and look over stored vegetables, Potatoes, and Apples.

FLOWER GARDEN.

Lawns and gravel walks will now be benefited by a thorough rolling. Examine all belts at the outskirts of the kitchen garden, remove deciduous trees where they injure the best evergreens, and introduce Hollies or trees of a permanent character in blanks. If not already done, stake newly planted trees carefully; the harm which has lately resulted from inattention to staking has in some places been very great. Procure Rose stocks, and plant them in lines on highly manured ground in the kitchen or reserve garden. Should heavy snow or severe weather set in, Pinks and Carnations planted in the open border will run some danger of destruction in those localities where hares and rabbits abound. I lately saw in a florist's garden, in the immediate vicinity of a large preserve, a simple and efficacious remedy. It consisted in laying small pieces of Larch spray or branches between the row of plants, and then placing other branches on the top of these; air and light have free access to the plants, and as spring advances the coverings are removed, for as vegetation progresses more palatable food in the shape of young Clover, &c., will entice the rabbits to feed at a distance. Tulip seeds may now be sown in a compost of equal parts of leaf mould and sandy peat. They may be placed at equal distances, almost touching each other, on the surface, and gently pressed down, covering with the same soil to the depth of an eighth of an inch. As the foliage of the bulbs planted in the main bed shows itself above ground it should be covered with sandy peat, but this must be done before it opens, as soil getting into the heart is very detrimental.

As soon as you perceive that the Auriculas have made a start give them occasional waterings with weak liquid manure; that made with sheep dung is best. Should premature blooms show themselves, allow the stem to rise high enough and remove the pips. To cut or pull the stem at this season often has an injurious effect on the plant, by causing it to decay down to the heart; by simply removing the pips this is avoided, whilst the plant is strengthened.

GREENHOUSE AND CONSERVATORY.

Among the plants in the mixed greenhouse may be enumerated Oranges, Lemons, Banksias, Chorozemas, Pimeleas, Epacrises, some Heaths placed in the most airy part of the house, with many other flowering plants interspersed. For the present apply air abundantly in suitable weather, but we shall certainly meet with a sudden atmospheric change. Correas, Polygalas, and Acacias will now begin to blossom freely; see that they are carefully watered—the Acacias require much moisture. Care must be taken that Camellias receive no check, otherwise their buds will be endangered. Brugmansia sanguinea, a noble conservatory plant, demands similar attention. Climbers should be neatly trained, and every plant that requires it, previous to being introduced into the conservatory, should be staked. At present we may expect this structure to be furnished with the following plants in flower: Luculia gratissima, Epacris, Euphorbias, Pimeleas, Boronias, Cinerarias, Gesnera zebrina, Eranthemum pulchellum, Primula sinensis, Pinks, Azaleas, Hyacinths, Narcissus, Tulips, and Neapolitan Violets. Of these the stove plants should be placed in the warmest part free from cold draughts or currents of air, and the New Holland, greenhouse, and others of the more hardy plants nearest to where air is admitted. Many of the plants will require frequent changing, and neither stove nor greenhouse plants should remain in this structure long enough to be injured.

STOVE.

Here there is a constant source of interest, many interesting plants being at all seasons in bloom, while others are making their growth, and some are resting. Place a few of the early-flowering Gesnera zebrina in the resting corner to ripen-off gradually for early flowering again. Select a few Gloxinias and Achimenes in variety, shake them out, and put the former in open turfy porous loam, heath soil, coarse charcoal, and sharp sand well incorporated, and do not pot too firmly. The Achimenes tubers should at first be placed thickly in pans, and potted singly as they push, in leaf mould and light loam in a very coarse open state, with a fourth part of charcoal. These two tribes of plants delight in a moderate bottom heat. See that no plant is suffering from want of water. Take advantage of the lightest days for applying the greatest portion of humidity. If the green fly prevails smoke occasionally with tobacco, and see that there is no other kind of vermin encouraged. Allow no plant to be injured from want of timely staking. Some of the Orchids which are commencing growth, if dry, may have a little water applied at the roots. This must be done cautiously. The best way is to apply it round the sides of the pot, taking care not to saturate the soil round the collar. See that the fresh potting material undergoes a kind of quarantine before it is introduced into the house. The blocks should be immersed in boiling water.

FORCING PIT.

No diminution of temperature must be allowed in the forcing pit. Pinks after they have made a little growth require to be removed to a cooler place, otherwise the buds will fail. Gardenias require a moist warm atmosphere. As the season is at hand when increasing the stock of plants will demand attention, prepare a place which will afford the required convenience. There is scarcely a gardener who is not called upon annually to apply his skill to replace the losses that invariably attend the occurrence of a rigorous or otherwise unfavourable season, and yet we rarely find a proper situation appropriated for the purpose. This is partially owing to the facilities which exist for propagating the plants principally in demand for decorating the flower garden, such as Pelargoniums, Fuchsias, and Verbenas, in the common plant houses; and we consequently see them crowded with pots of cuttings to the destruction of order, besides being the means of introducing various insects. I would recommend a small pit constructed with beds to contain plunging materials, and provided with a heating apparatus capable of supporting a bottom heat of 90°. This, with a complement of bell-glasses, would enable the gardener not only to obtain his stock of summer plants with certainty and expedition, but give him the opportunity at the most suitable seasons for multiplying rare plants and those difficult to strike. —W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Owing to the wet weather the work has been very limited. An opportunity has been given for sweeping the walks, and the rains have washed them clean and solid.

The mild weather, though so wet, has been favourable to all the hardier vegetables, and tall Scotch Kale headed is now showing fine side shoots, which I always consider much better than the main heads. We have been taking the small heads

from a late piece of Brussels Sprouts, as these heads are very sweet and different in flavour from the knobs at the sides. The earliest have produced plentifully. Cauliflowers under glasses have had the soil pricked over with a small fork, and a little dry sandy compost added; for though uninjured as yet, such continued damp is apt to affect them. Lettuces on ridges are not so large as they were, but a change of weather will revive them. All under glass will be the better of a little dry surfacing, which will give them a drier atmosphere.

The weather has afforded a good opportunity for pointing sticks and stakes, making tallies, washing pots, cleaning glass, and washing and limewashing the walls of pits and houses.

Washing Pots.—On the whole nothing is better than a vigorous scrubbing with water heated enough to be comfortable. We have used other means to remove the green and slimy matter that will accumulate, and though the cleaning is more quickly done, the pots often retained something undesirable from the processes used. The same may be said of woodwork and glass. For them weak warm soap water will be an improvement, but if the soap water is strong, or contains much soda, paint and putty will suffer loss or more.

Limewashing walls is often done very inefficiently. It is easy to draw the lime-brush over, and thus hide for a time all the filth beneath, but though this is better than nothing in a cottage, it is but a poor makeshift, as the dirt is not removed, but for a time merely covered up. It is just the same as respects the walls of our plant houses. Such washing, even, does not greatly protect us against insects, as repeated coats are sure to crack and admit the air to the eggs of insects. Though requiring more time, it is time well spent, to wash away most of the old limewash with warm water before adding the fresh lime. This limewash should not be so thick but that it will enter freely into every hoe and cranny of the walls. The fresher the lime the more firmly it will adhere. To secure this object much also depends on the temperature of the water used in making the limewash; hot water is in every way superior to cold water. Limewash will set all the more firmly from having a portion of Portland cement mixed with it immediately before using it.

FRUIT GARDEN.

In fine dry days we proceeded with pruning, and preparations were made for planting, but the ground was too wet to pack roots as they ought to be. Excess of moisture is anything but advantageous to small fibres. It helps to rot them, instead of to encourage growth. Late Grapes hanging, required a brisk fire and air in the early part of the day. The only thing to be done with Peaches in bloom was to give more heat and air during the day, and to keep them rather cool at night. A few hours' sun would do much good.

The gales here have been very severe. Early on the morning of the 24th our barometer was considerably below 28 inches, the lowest we had ever seen it, but as day began to break it rose, and in the forenoon quickly. Such a gale would try some of our new modes of glazing, and reports would be very interesting. By using small wedges to sashes we suffered no breakage of glass, with the exception of one small ventilator, 20 by 24 inches, hinged by two screws as pivots, which was blown out and smashed. The great danger of using large squares, as for orchard houses, and glazing in the usual way, is that if a large square or two go out, the wind gets in and unsettles a number more. So long as the wind is kept out there is little danger. In this respect placing the glass in grooves instead of on rebates with putty, is safer, provided the grooves allow of expansion, and the glass is still firm enough not to slide or rattle and let the air in. We have heard much about having a breeze, if not a gale, in our fruit and plant houses, but it is often the wisest policy to keep such rough visitors outside.

ORNAMENTAL DEPARTMENT.

Wooden Rollers.—The mild weather has encouraged worms to throw up their heaps on the lawns, and thus disfigure the bright green the grass would otherwise present. Sweeping is not to be thought of in such weather, nor in any weather if there are no leaves or bits of wood, as well as the worm heaps. The wooden roller soon puts the latter out of sight. A young man can walk quickly with a roller a foot in diameter and 3½ to 4 feet long behind him, and the comparative lightness of the roller is an advantage for this purpose. Part of the worm heaps is squeezed down out of sight, and part adheres to the roller, and must frequently be scraped off with a piece of hoop iron or wood kept on purpose. Next, or even equal to the Daisy-knife in summer, nothing will so soon improve the appearance of a lawn in winter as a light wooden roller.

Planting and Transplanting.—We proceeded with these operations, though in the latter case we had to bale the water out of the holes that had been made previously. When the soil is too wet the packing of the small roots and fibres cannot be done in a satisfactory manner. Drenching the roots of large specimens on planting in winter we have long considered a mistake, as it keeps the roots long wet and cold as if embedded in a morass. The water would be beneficial if judiciously given just as the buds and roots begin to move.

The weather furnished an opportunity for potting, tying, training, and washing plants that otherwise might have had nothing more than a skiff from the syringe. A good syringing, a wash, and then another syringing, by keeping foliage clean and healthy, are the best safeguards against insects. Two great preservatives against insects are a comparatively low temperature at night, and avoiding a high temperature and a dry atmosphere during the day. Unless these conditions are secured red spider and thrips will soon be your acquaintances. There are some insect enemies that you can hardly eradicate, unless you crush them, bury them, or freeze them out of existence. The mealy bug is one of these. You may manage to clean every plant in a house, but if every crack and joint of your platforms of stone, slate, or wood be not thoroughly examined the enemy will soon reappear in as strong force as ever. If there were no climbers, and the plants could be removed from the house, a free application of hot water alternately with exposure to frost, would be the most effectual remedies.—R. F.

TRADE CATALOGUES RECEIVED.

P. Lawson & Son, 20, Budge Row, Cannon Street, London, E.C., and George IV. Bridge, Edinburgh.—*Catalogue of Kitchen Garden and Flower Seeds, &c.*

W. Rumsey, Joyning's Nursery, Waltham Cross, London, N.—*Select List of Garden, Flower, and Farm Seeds, Border Plants, Evergreens, &c.*

Edwin Cooling, 18, Iron Gate, and Mile Ash Nurseries, Derby.—*Catalogue of Seeds.*

Smith & Simons, 36 and 38, Howard Street, St. Enoch Square, Glasgow.—*Cultural Guide and Descriptive Seed Catalogue.*

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Catalogue of Flower, Vegetable, and Agricultural Seeds.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

CHAMEROPS EXCELSA CULTURE (*J. S. G.*).—This Palm will undoubtedly succeed in a Wardian case with but little attention. But why put it in a case? In our opinion it is only taking up valuable space unnecessarily, because it will live and thrive admirably in any apartment of which the temperature does not fall lower than 38° or 40°, and few rooms are colder than this. We have had many species of Palms, Chamærops excelsa amongst them, in our rooms for three years or more, and they grow well, and are really charming objects for such situations. C. excelsa requires to be grown in about equal parts of loam and peat mould; the drainage should be good, as it enjoys copious waterings during summer. This, and sponging the leaves occasionally with warm water to remove dust and dirt, are all the attention required. It is a native of the Himalayas, attaining a height of about 30 feet.

MANETTI STOCK FOR FORCED ROSES (*T. Mayes*).—The Manetti stock is well adapted for the forcing of Roses, care being taken to bury the collar of the plant at least 2 inches below the junction of the scion and stock. A liberal treatment is required, and proper attention must be paid to remove all the dormant buds in the Manetti stock previous to potting, and to be careful not to let a sucker appear. Use good-sized pots, plunge and mulch in the summer, and well ripen the wood. Avoid worms, which are very liable to do damage when pots are plunged.

TRUFFLES (*W. J. W.*).—Write to Messrs. Webber, Central Avenue, Covent Garden Market, and ask for the information you need.

LIST OF ROSES (*T. Watson*).—Though your Roses, as per list sent, are not entitled to rank on the whole very high, yet with the exception perhaps of General Washington, which is too uncertain to trust to, we should not advise you to cast any away, but recommend you to procure a dozen more if you can find room for them, selecting them from the list of the thirty-six best, as by the return sent by Mr. Peach. Souvenir de Malmaison will take a long time to cover a wall 8 feet high and 4 feet wide, if ever it do so. We should recommend Gloire de Dijon. Your suggestion of planting Clematis Jackmanni alongside will do, if you train the Clematis up at once and make it cover the top part of the wall. Madame de Cambacères, good hardy Rose, rough petals; Lord Raglan, purplish red, too flat, occasionally good; Countess de Morny, fine bright pink, good; General Washington, very uncertain; Beauty of Waltham, good, cherry red; Grant des Batailles, very free-blooming; Anna de Diesbach, fine pink, too loose-petalled; Mrs. Bivers, blush white, shy grower; Empereur de Maroc, dark plum, small flower; Anna Alexieff fine garden Rose; Souvenir de Chas. Montault, uncertain, occasion-

ally good; Souvenir de la Reine d'Angleterre, rather coarse; Coupe d'Hébé, fine shape, pink, a summer Rose; Kate Hausburg, deep red, doubtful; Lord Clyde, in some soils very good; Rev. H. Dombrain, a Bourbon, uncertain, but sometimes good; Lord Macaulay, very fine, dark crimson, good; Madame Louise Carique, light rose, good.

VARIEGATED IVY (*J. S.*).—The Ivy you send is H. palmata, or so near to it that it is not worthy of introduction as a novelty. If you trace the wild forms of this beautiful plant in its native habitats, you will find a wide divergence in the sizes and forms of the leaves.

POMEGRANATE (*R. E. H.*).—It cannot be grafted on a Lemon stock.

CARVING PLANS INTO PRACTICE (*Ignoramus*).—A series of directions have been published in our columns.

DEFECTIVE FLUE-HEATING (*H. S. W.*).—To prevent your fire burning so furiously you will find that a damper fixed in the chimney will regulate your fire just as you wish, but if your flue is at all faulty the smoke will find its way into the house. Another remedy is to fix a door to your ashpit, the same as to your firehole, and by closing both you will prevent the rapid combustion by excluding the air. A far better plan will be to fix a sliding door to each opening, as fitted to boilers when hot-water is used for heating. Any horticultural ironmonger can supply one.—(*From a Correspondent, T. S. S.*)

DEODORISING SEWAGE.—*A Constant Subscriber* has a manure pump to the sewage pit which throws the sewage water into a smaller tank from which it is used for the garden, and he asks how to deodorise this supply in the small tank before using it, with the best and cheapest deodoriser, and the quantity that will be required. The earth of the garden will be an efficient and the cheapest deodoriser. If the sewage be pumped into the small tank daily, and enough earth added to make it into a very stiff mud, there will be little or no offensive smell.

CYCLAMEN PERSICUM NOT THRIVING (*S. P. S. X.*).—We are unable to account for the decay of the corms, unless by their having been too quickly dried-off. The forcing temperature to which they were subjected to flower them in a greenwemonth, and the planting out-doors in the following summer, may have acted injuriously on them. If you had given them a gentle bottom heat on potting, and kept them near the glass in a temperature of from 50° to 55°, we think they would have done better. From the leaves we should say your plants are suffering from cold and damp. Give more air, a position close to the glass, and a temperature of 45° to 50°. We consider the best summer treatment of Cyclamen persicum is to plant it out in a cold frame shaded from the mid-day sun, to keep it lights on constantly, but tilted back and front, and to repot in August. When the corms begin to grow remove them to a house with a temperature of 45° to 50°.

STOPPING YOUNG PELARGONIUMS (*A. R.*).—Do not stop the young plants a foot high, but let them go to flower. When that is past and the wood firm, cut them down to three or four eyes. You may, if you like, cut them back now to three or four eyes, in which case they will be more dwarf, and will not flower until late.

HEATING CUCUMBER AND MELON HOUSE (*D. J. E.*).—A flue for a small house is more economical than heating with hot-water pipes, though the latter is on the whole much better. We advise you to use a small saddle boiler and hot-water pipes. The bed should be 5 feet wide and heated with two rows of 3-inch pipes for bottom heat, and four rows of 4-inch pipes for top heat. A foot of rubble should be placed over the pipes, and on that a foot of good rich soil. We advise you to adopt the plan practised by Mr. Douglas, and described by him in the Journal for January 18th.

TRANSPLANTING RHODODENDRONS (*Subscriber*).—The best time to transplant Rhododendrons is during September and October, and if mild from the middle of February up to the second week of April. Last year we planted several hundreds in May, indeed the Rhododendron can be lifted with such good balls that they may be safely removed at any time of year, though the times named are preferable. *Twelve select Rhododendrons* are Blandyanum superbum, light crimson; Brilliant, crimson scarlet; Coriaceum, white; Marian, shaded pink; Paxtoni, rose; Ochroleucum, pale yellow, centre shading off to straw brown spots; and Vivicans, bright scarlet. These are of dwarf habit. The following are of excellent habit, but larger-growing:—Nero, rosy purple, finely spotted; Old Port, plum; Mrs. John Clutton, white; Alarm, white centre, deeply scariet-edged; and Lady Dorothy Nevill, purple, spotted black.

SELECT HALF-HARDY ANNUALS (*B. B.*).—Of novelties Amaranthus salicifolius must take precedence. Ageratum Imperial Dwarf, Phlox Heynholdi and cardinalis, are three good novelties; Tagetes signata flore-pleno, Brachycome iberidifolia, dwarf striped French Marigold, Lobelia speciosa, Aster Victoria, vars., large-flowering Ten-week Stocks, Phlox Drummondi, vars., Schizanthus retusus, and Venidium calendulaceum.

FICUS ELASTICA NOT THRIVING (*Château Vallon*).—The leaf sent has every appearance of having been destroyed by some solution, and we think the plant is also suffering from cold and damp. Keep it drier at the root; indeed, give no more water in winter than will be sufficient to keep the leaves fresh. When a growing copious supplies are required. If you could place the plants in a house with a moist growing temperature of from 50° to 55° at night until they make fresh growth and roots we think the foliage would become healthy.

PROPAGATING CAMELLIAS (*Ignoramus*).—You must procure stocks of the single varieties, either by sowing the seeds or raising plants from cuttings of the ripened shoots inserted firmly in sand, in a close cold frame, shading for about a month, and then placing in a gentle hotbed. The plants from cuttings must be grown until they are strong enough to graft. This must be done in April, before the scions begin to grow, placing the worked plants in a mild sweet hotbed. Camellias are easily increased by inarching, elevating the stocks on pots or other contrivance to the height needed, but you must first secure the stocks. Keane's "In-door" and "Out-door Gardening" would suit you. They may be had by post from our office for 1s. 7½*d.* each.

PRIMULA SEED—AZALEAS AFTER FLOWERING—CROTON LEAVES GREEN (*St. Honoré*).—Primula sinensis fimbriata alba, P. sinensis fimbriata rubra, P. sinensis fimbriata lilacina marginata, will give you white, red, and lilac. They may be had in separate colours from the principal seedsmen advertising in our columns, of whom we draw our supplies, and they are extra fine this year. Order Cineraria seed saved from a fine collection. The Azaleas from which you have removed the flowers should be placed in a house with a night temperature of 55° to 60°, and be syringed, and a moist atmosphere maintained until the growth is complete, and then they should have a more airy and cooler house. The Croton may have lost its leaves from an attack of thrips, or from being kept wet at the roots in a low temperature. Examine the drainage, repot if needed, afford the lightest position you have, do not overwater, and with sunny weather your plant will have the fresh growths well coloured. Crotons require light to colour well.

VINE CULTURE (*Ignoramus*).—In planting a vinery it is desirable to arrange for two permanent rods to each Vine. To obtain these we would train up at least three shoots, and when pruning the Vines in autumn we would select the best two, entirely removing the third. It is not usual to allow shoots to grow on the upright part of the stem before it reaches the rafters. You can rub off the buds with your fingers as they appear.

SELECTION OF VINES (*H. Coe*).—You can grow all the Vines you name in a heated house with Black Hamburghs. Plant the Muscats at the warmest end of the house, but it is not desirable to grow them with Hamburghs.

SCALE ON ORCHARD HOUSE TREES (*An Old Subscriber*).—The small scale on your trees is very difficult to dislodge; we have had it on our own pot trees, and rather than risk the contamination of the others we have destroyed the trees. As soon as the leaves fall in autumn we would scrub the trees with a mat brush, using warm rain water in which soft soap has been dissolved.

FLOWER GARDEN PLAN (*An Amateur*).—We like the arrangement. If 3 and 6 had white centres the whole would be improved. We think that 9, the centre, would be improved by Lobelia half-circle edgings instead of Cerastium.

CHARCOAL ASHES (*Curious*).—They are neither more nor less than the ashes of the wood from which the charcoal was made. They will not do as a substitute for lime rubbish in making a Vine border.

KILLING LICHENS ON FRUIT TREES (*Cheriton*).—Paint them over with a strong mixture of quicklime and water; or scrub them with a brine of salt and water.

GIANT TRIPOLI ONION (*St. Edmund*).—Transplant as early in spring as the weather and state of the soil will permit. The ground should be dug 18 inches deep and well manured. We would not use the iron roller, as it is probably too heavy if of the kind used for gravel walks. A wooden roller is the best; if you have not one the ground may be beaten lightly with the back of the spade, if not naturally of a heavy nature. Plant 8 or 9 inches apart in rows a foot from each other, placing only the fibres below the surface. A dressing of pigeons' or fowls' dung sufficient to cover the surface will be an excellent manure. If used in a liquid form, an ounce to a gallon of water is sufficient.

DRY EARTH CLOSETS (*Inquirer*).—There can be no question that these answer well, if the dry earth is kept in stock ready for use. No perceptible taint is discovered. There is no other mode known to us by which such a quantity of the richest manure can be obtained without distressing our quantity of the richest manure can be obtained without distressing our organs of smell. Carbolic acid will be a great help in neutralising the smell from water-closets, house sewage, &c., but more definite experience is still required, for the whole question of sewage is still to be thoroughly considered. Traps used in drains are in most cases too shallow to prevent the pent-up gases forcing their way through them. No trap should contain in such cases less than from 3½ to 4 inches in depth of water.

SALARY (*Idem*).—We are quite unable to state what the salary should be of an overseer of an estate of from seven to eight thousand acres, though combining the offices of gardener, forester, &c. We have known places of eight hundred, nay, of eighty acres, requiring more management than such a large estate. It entirely depends on what is wanted, and what is done. We have known cases in which such work has been done by one man for £150 a-year, horse kept, &c., but it would have been true economy to have had three men with wages of from £90 to £100 each. We have known large estates superintended for very insufficient wages, and yet the superintendent got rich. We hope that for the credit, respectability, and true manliness of all concerned, work or service given will be directly paid for in wages without makings-up dependent on any left-handed or under-handed sources.

BOILER (*Camjee*).—We hardly understand the question. We prefer saddle boilers chiefly because they are simple, but we do not think there is anything to find fault with in any of the forms of boilers advertised in our pages. Another correspondent wishes to know whether cast-iron or wrought-iron boilers are best. Our experience is, that for all boilers of moderate size, cast iron is to be preferred, but for large boilers, say saddle-backs, from 5 feet in length, wrought iron is better. The larger the casting the greater is the difficulty of having it regular throughout.

WINTERING GERANIUMS IN A SPARE ROOM—FORCING ASPARAGUS OUT OF DOORS—TRENCHING (*Amateur*).—The cause of the old plants of Geraniums shrivelling is want of moisture at the roots, or it may be the dry air of the room. We advise you not to give much water before March, but it is of course necessary to keep the stems fresh. On each side of the Asparagus bed you may now take out a good trench 18 inches or 2 feet deep, and 2 feet wide, fill that with hot dung to 18 inches above the level, and cover the bed with wooden shutters resting on the fermenting material. The shoots will be fit to cut in three weeks or a month. You must renew the fermenting material as the heat declines. It is not too late, nor is it ever too late, to trench or double-dig ground. Do not bring up too much of the bad soil, but loosen it, and dig ground. Do not bring up too much of the bad soil, but loosen it, and dig manure. We advise you to put to give a dressing of well-rotted manure at the surface, and to point-in with a fork.

DRAINING A GARDEN (*C. S.*).—As there is no outlet for water at the proper level, your only plan will be to have a well as you propose, and that will be useless unless you have a pump to keep the water below the mouth of the drain conveying the water off the land; but as water is so much required during the summer in a garden, we should have the well, which will give the outlet for the drainage water, and if the water in the well rises level with the drain-pipes, or above them, make a reservoir, which may be a small pond puddled at the sides, and with a pump draw the water from the well, always keeping it below the drain outlet; in the reservoir it will be available for watering purposes. The well need not exceed 8 or 9 feet in depth, and about a yard in diameter; brick it round, and by having an indicator alongside of the pump you may tell exactly when the water should be pumped off. Three drains the whole length of the ground will be sufficient, and we should have them 5 feet from each side, and 15 feet apart, running lengthwise of the parallelogram, and brought to one main 6-inch pipe before reaching the well, though each drain may have its own outlet into the well. Three-inch pipes would be best, let them have a fall of 2 feet in the 100 yards. The depth of the drains should be 4 feet.

FORCING VINES AFTER REMOVING THE SURFACE SOIL (*B. G., Subscriber*).—After removing the soil down to the roots and putting-in fresh, we do not see any objection to your starting the Vines in the course of two or three weeks. Cover the border with 18 inches or 2 feet thick of fermenting materials, so as to set the roots to work before the growth of the top commences. If you did not place heating material on the border, but left the soil to be

heated by the sun, the forcing would probably tend to weaken the Vines, in consequence of the growth of the top being in advance of the roots, which would in part be destroyed by the removal of the soil.

Covering for Frames (*R. H. F.*).—Shutters made of rye or wheat straw are the best, but not nearly so durable as those of wood, which are the best of all. They should be slightly raised above the frame so as to admit air, but if this be done the frame lights should first be covered with mats, and then with the wooden shutters. The space need not exceed an inch, and an ordinary frame may be put on close, as, from the glass being lower than the wood bars, a small space will be left between the shutters and the glass, which will be closed in severe weather by the mats.

Hollyhocks (*Inquirer*).—Your mode of treatment seems to us to be quite correct, and we do not know how we can assist you. Probably something is radically wrong with your soil or the site. Hollyhocks like an open situation exposed to the full sun, and require to have plenty of air, but to be sheltered from cutting winds by objects at such a distance that they will not shade nor affect the Hollyhocks. The ground should be a good rich loam, light rather than heavy, enriched with plenty of manure; it must be trenched, manured, and thrown up roughly in November, and turned over in frosty weather. Of course, it must be well drained. If the ground is heavy add sand or ashes to the soil. If it is in good order you may plant out with every confidence early in April. The plants should have protection from frost for a short time. Beyond staking, and supplying them liberally with liquid manure, we do not find they need any further care, only to reduce the shoots thrown-up to two, or at most three, of the strongest. *Twenty-four good sorts* are:—Brilliant, rosy scarlet; Conquest, scarlet crimson; George Johnston, rosy crimson; Lord Napier, scarlet crimson; Midnight, deep glossy maroon; Marvellous, deep orange buff; Sir John Sinclair, rosy salmon; Mrs. P. Bruce, light rosy peach; Joy, delicate flesh; Jewel, bright yellow; Mrs. F. H. Douglas, light rose; Alba superba; John McDonald, dark ruby crimson, Marion, purplish rose; James McIndoe, rosy crimson; Andrew Jamieson, deep rose; Sovereign, claret crimson; The Prince, deep buff; Walden Queen, delicate flesh, flushed with rosy carmine; R. T. Mackintosh, rosy crimson; John Gair, rosy peach; Her Majesty, white, slightly shaded; Fred. Chater, pale yellow; and Mrs. Downie, soft salmon rose.

Apple Tree Diseased (*W. H. Bennett*).—The disease on your Apple tree is caused by American blight (Aphis lanigera). We have found boiled oil an effectual remedy; we simply applied it to the affected parts with a small brush. We found the insect appear to a limited extent six months afterwards, and another application effectually destroyed it.

Verge-cutter (*J. Lumley*).—In our last volume, page 380, you will see a drawing of one invented by Mr. McLachlan. What yours may be we do not know, but we think your only course to gain anything by it will be to offer it to some of the large implement-makers.

Destroying Worms in Lawns (*J. H.*).—It is true that corrosive sublimate, about half an ounce to fifteen gallons of water, will compel worms to come to the surface, but any fowls that ate them would be poisoned. Lime water made by thoroughly mixing a peck of freshly-made quicklime with forty gallons of water, and when quite clear applying it through a rosed watering-pot, will be as effectual.

Names of Plants (*J. Bell*).—Odontoglossum Cervantesii, *Lindl.*, a very pretty species, very similar to O. membranaceum, *Lindl.* (*Robert*).—The Christmas Rose, Helleborus niger. (*J. T. L.*).—Eupatorium glabratum, native of Mexico; a plant we have seen cultivated in gardens under the erroneous name of Ageratum glaucum. (*A Market Gardener*).—1, Pteris longifolia; 2, Asplenium flaccidum; 3, Litobrochia respertilionis. (*A Constant Reader*).—1, Asplenium Trichomanes; 2, Pteris longifolia; 3, Blechnum polypodioides; 4, Cereus flagelliformis; 5, Pellia epiphylla, in all probability, or perhaps P. calycina, one of the Liverworts. We recommend you to adopt your idea of damping your Ferns overhead, modifying it, however, according as the weather is bright or cloudy. The Brunea might become so affected by being in a current of dry heated air, or by defective watering, or by the soil becoming foul, either from the presence of earth worms or defective drainage. (*Paquanil*).—1, Probably Aspidistra lurida variegata; 2, One of the smaller-crested varieties of the Lady Fern (Athyrium Filix-fœmina); 3, Not in good condition, probably Cystopteris fragilis; 4, Nephrodium glabellum; 5, Young state of Polystichum angulare; 6, Asplenium marinum. (*J. G.*).—1, Asplenium flabelliformis; 2, Polypodium vaccinioides; 3, Probably Leucostegia immersa; 4, Asplenium Veitchianum (otherwise known as Bellangeri); 5, Pteris pellucida; 6, In very bad condition when received, probably Hypolepis repens. (*Quercus, Cork*).—Elæagnus arborea variegatus.

POULTRY, BEE AND PIGEON CHRONICLE.

FOWLS FOR PROFIT, AND AS A MEANS OF SUBSISTENCE.—No. 1.

The rearing and management of poultry as a source of income is, generally speaking, very little understood. In putting these papers before the public I shall endeavour, as briefly and plainly as possible, to show every poultry-keeper how his or her poultry-yard can be converted into a valuable source of income, instead of being, as is usually the case, an ill-arranged non-paying business. The invariable answer I receive to any question I propound to the small farmer or cottager with regard to the economy of keeping poultry, is, "Oh, sir, they don't pay." Now I have enjoyed a life-long experience in fowl-keeping, and know that they not only do pay, but that to those who economically and properly manage them they will afford a valuable means of subsistence. This may appear to some a startling assertion, nor do we wonder that it is so when we see daily such ill-bred pigmy specimens, utterly unworthy of the name of poultry, but which are annually bred often to the positive loss of the owner. I will state plainly what anyone may easily make by poultry, without in any way teaching extravagant views. I have calculated the profits in moderation, and the expenses are quite as large as they will ever amount to if strict attention be given to the birds and to their requirements; and what line of business can be expected to return a profit unless attended to?

Selection of Breed when Unconfined.—No cross-bred fowl will produce as many eggs as one which is pure bred. Now as the largest number of eggs that a hen is capable of producing is required, and that the largest and finest-fleshed fowls and chickens must be obtained to make a poultry-yard pay in perfection—my advice, founded upon reason and experience, is that two breeds must be kept. As I am regarding the domestic fowl solely as a source of profit, the greatest importance must be attached to obtaining the proper breed, as there are many breeds which will not pay as egg-producers, and others, on the contrary, which if reared for the table or for market purposes would be a positive loss.

Proceeding upon the assumption that the fowls have the advantage of a good run, say a field or farmyard to roam in, I should recommend the Black Hamburgh fowl to be kept as an egg-producer; it is truly called an everlasting layer, and will, without doubt, produce fully twice as many eggs of ordinary size that any other known breed will do. It is a noble-looking bird, and brilliant black with a metallic lustre. This breed is non-sitting, therefore we must keep another breed for the production of chickens; and I would strongly recommend the Brahma Pootra; the chickens rapidly put on flesh, and grow to a very large size, being fit for the table at the age of three months. The hens are good sitters and careful mothers. They will become broody in the winter, if attention is paid to their feeding and they are warmly housed; but should this not always happen at the time wished, a hen may be persuaded to sit at any time of the year. The Brahma chicks being naturally strongly constituted, will thrive well at any season. I would not advise a sitting of the Hamburgh eggs to be made before March.

It has often being urged as an obstacle against keeping two distinct breeds of fowls that there is a difficulty in keeping them separate. It is of course imperative that this should be done, for if the cock of either breed were to obtain five minutes' freedom in the poultry-yard or range this mischance would spoil the breed for twelve months. This difficulty may be easily obviated by keeping the cock always confined, which is a very simple matter, as will be seen in a subsequent paper. The age of the cock should not be less than twelve months, nor should he be kept after he has attained his third year. Six or seven hens are sufficient for one cock, but where a number are kept, say twenty-five hens, three cocks will be sufficient.

As profit is our object, the pullets hatched in the spring must not be kept after the July or August twelvemonth, as they will then moult and become for some time unprofitable. The cockerels of each sitting, no matter when hatched, must be sent to market or used for the table when from three to four months old. If kept longer than this they must remain until full grown, as they always fall off in condition after the period of chickenhood is terminated. At this age they ought to weigh not less than 5 lbs. each, and I have known them to be heavier. The hens may be kept for sitting until three years old; they are better sitters, generally speaking, than pullets, but after that age they often become cross-tempered, and should be replaced by younger birds. I have heard of capons having been trained to rear young chickens, so that the hen may recover her vigour and begin to lay again. Of this I have not had any experience; and as the Brahma fowl will generally lay again in a few weeks, and at the same time take charge of her brood, when this breed is kept it is unnecessary to deprive the mother of her own progeny.—Vincent Fraser.

A PLEA FOR JUDGES AT POULTRY SHOWS.

I believe every exhibitor of poultry will endorse the remarks made by "D.," of Deal, on poultry-judging. I have been an exhibitor and breeder of poultry for the last twelve years, and never have I heard such complaints—loud and long—from men who do not generally grumble, as during the season just past. It is essential, I fully believe, to remedy this state of things, and that judges must have one entire day to make their awards. More judges must be employed; and at the largest shows, and where the funds will permit, as at Birmingham, the Crystal Palace, Bristol, &c., amateur breeders of the different varieties should be solicited, and would be glad, I doubt not, to give

their services to the judges to revise and overlook their awards; and I believe then we should not have the egregious mistakes we now have, nor the caprices in judgment. Uniformity in the awards would be the rule and not the exception. Birds that are one year considered the perfection of colour, style, size, and everything else, are the next year totally discarded, and the award given to directly opposite. What is more puzzling and disheartening to an exhibitor and—A BREEDER?

AMATEURS AND DEALERS EXHIBITING IN THE SAME CLASSES.

I HAD hoped that some abler pen than mine would have backed up Mr. Ashworth's remarks a week or two since on the above subject (page 455). I know of no other matter in connection with poultry exhibitions more worthy of consideration than this. The present arrangement of classing the amateur and dealer together is to my mind most unfair and unsatisfactory. The amateur keeps his few poultry or Pigeons as a pastime or hobby, often to pass away a pleasant hour after returning from his business; in fact, he merely keeps them for the love of them and not for profit. Still, he likes to exhibit them occasionally to see whether his are as good as his neighbour's over the wall. The dealer, on the other hand, bestows most of his time and all his ingenuity on his birds; in fact, it is his trade and his sole occupation, and it is but rarely that his birds return from an exhibition without bringing the lion's share of the highest honours with them—not that they do not deserve them; but what chance has the amateur against a man who makes exhibition his trade, often taking dozens of prizes with the same birds, and putting them in the catalogue at a price prohibiting their purchase except rarely? My impression is that the committees of the various societies ought to place the dealers in a class by themselves.

I cannot endorse Mr. Ashworth's opinion that the Selling class would be the place for them, as in most instances the price of the birds in this class is restricted to a mere nominal figure, far below the value of a first-class bird. This would not encourage the dealer to show his best birds. What I would advise would be to place the dealers in a class by themselves on the same footing as the amateur, and let it be dealer against dealer, amateur against amateur. I have no doubt but that the class would pay any and every committee that adopted the plan, and would be far more satisfactory to all parties concerned than the present system.—AMATEUR.

HOW SHOULD FOWLS BE FED AT SHOWS?

I AM very glad indeed to find this matter taken up by "WINNER OF FOUR CUPS." I have long been of opinion that the great havoc made amongst birds every year after returning from shows, has been caused by the absence of digesting materials afforded them at those shows. I have had many complaints from breeders in England this year that their birds returned from exhibitions diseased.

Now, I believe there was no disease in the matter, for none would think of sending diseased birds to such shows as the Crystal Palace and Birmingham. One gentleman told me it was black roup that was the matter with my Crystal Palace cup cock. I will give you a description of how it affected my bird and how I treated him, and let your readers judge whether it was black roup or not—and breeders in England say their birds were exactly in the same case. When my bird returned from the Crystal Palace Exhibition I gave him bread soaked in ale, but as he did not seem to relish it, I offered him his usual food (oatmeal dough); of this he took a moderate meal. When I took him out of the basket there was nothing whatever in his crop, or first stomach. The above food, though not half a meal, remained in his crop next day, and I gave him a dose of castor oil but with no effect, followed by other three, and one of salts, but all to the same purpose; indigestion had fairly set in, and the food refused to enter the second stomach. The bird was in this state for about eight days, and now his comb was as black as if painted with black paint. As a last resource I gave an emetic, and took back the last particle of the food. I by this time came to the conclusion that the second stomach was glutted-up with leaven or some other soft food, and, nothing to grind it, there it would lie. I then took fresh butter and kneaded it with sand and small stones, and put it down his throat, and as soon as this got into the second stomach, which was about twelve hours, the bird began to look about him and gradually recovered; in two days afterwards he could eat anything and everything. He recovered and became perfectly well again, but minus his beautiful comb, and, of course, for ever useless for exhibition.

I do not know what food is given at the Crystal Palace Exhibition, but if the fowls are not well attended to with sand, small stones, and lime (so used), especially the last two, it is quite sufficient to account for all the disease that has been amongst the birds returned from the Crystal Palace and Birmingham Shows. If birds are confined for twenty-four hours, even allowing them sand, then give them full liberty, and the first thing they will do is to rush to the heap of lime-rubbish and pick up good large balls of it. If they do this after twenty-four hours of confinement, how much more after eight days' confinement—four days going and returning per rail, and four in exhibition.

I believe the journey has very little to do with the disease. Strong-constitutioned birds ought to be able to endure the fatigue of travelling without the slightest fear of fatal consequences, for I have sent birds on approval to Brentwood (more than six hundred miles), and other places in England, and had them returned the same distance with not the slightest bad effect, because not long confined from their natural food. Yet when returned they refused to look at food though offered, but went about picking up stones and lime. I think green food, cabbages or Swedish turnip leaves (the latter they prefer), should be cut small and given freely at shows. The cockerel returned me from the Birmingham Show was very nearly as bad as that from the Crystal Palace, and was so ill that I could not send him to Edinburgh, and he could not make up condition in time for Aberdeen, and had to be content with an inferior position.—JAMES CLARK.

LOCAL JUDGES.

IN "our Journal" I have occasionally seen complaints against the mismanagement of poultry shows, and I consider the most glaring defect, and the one most likely to bring our shows into disrepute, is the Judges engaged.

There would, perhaps, be less cause for complaint if these Judges were men of enlarged experience; but often I find they have neither kept nor studied the fowls they pretend to judge; and whether the prizes happen to be correctly awarded or not, still there is among exhibitors much dissatisfaction, and even suspicion of unfair play. In a recent number of the Journal the Committee of a show give the names of four Judges from the town in which the show was held, besides several from the neighbourhood. "Would you not be astonished to learn" that there were at least other three local Judges for poultry whose names the Committee preferred to exclude from their catalogue? As an instance of the judging, I ought to mention that in a class for Red Game, the second-prize pen contained a cock with a twisted breast, and the legs of the pair were a very bad match. The third-prize pen contained a cock almost in the last stage of disease; and this was not the only diseased bird that took a prize and was allowed to remain in the pen to the end of the show. The Committee plead economy as their excuse; they may find next year that it was false economy.—PAISLEY.

WARNING TO EXHIBITORS AND RAILWAY COMPANIES.

To the late Barrhead Show I sent a pen of Duckwing Game and a pen of Black Red Game; both pens were awarded first prizes. The Duckwings had taken a first prize, and the Black Reds twice a first prize, and timepieces in both cases as extra prizes, only a few weeks previously at shows in the same district. The Barrhead Show happened to take place on a Saturday, and I asked the Secretary to favour me by returning my birds on the same evening, not wishing them to remain over Sunday; this was accordingly done. I waited their arrival at Edinburgh, and while at the station opened the basket to see that all was right before driving them home, and to my horror found all the four birds nearly dead. One died in a few minutes, the others soon afterwards—only three hours after leaving Barrhead Show. I at once concluded they had been poisoned, or had received foul play, and at once communicated with the Secretary and others connected with the Show to try to find out the cowardly rascal guilty of such an act: but all say the birds were in good health and spirits while at the

Show, and that the party who put them in the hampers is willing to give his oath that they were all right then. I have had one of the birds subjected to analysis, and enclose herewith a copy of the report. I merely write this as a warning to exhibitors sending birds to shows, as it seems that poultry committees are not responsible for cases of this kind, and the loss falls all upon the exhibitor, such being my experience. I shall only say in conclusion that if such cowardly acts as this were to occur often poultry shows would soon be a thing of the past. —D. Harley, *Rose Bank, Bonnington Road, Edinburgh.*

"Chemical Laboratory, Leith, 12th Dec., 1871.

"Report of analysis of contents of gizzard of game cock.

"On Tuesday the 28th of November last Thomas Bell left with me at my laboratory the body of a Game cock belonging to Mr. D. Harley. I have carefully, in accordance with instructions received from Mr. Harley, examined and analysed the contents of gizzard, &c., and have now to report that the results of my experiments are conclusive in showing arsenic to have been present in considerable quantity.—(Signed) J. Falconer King."

[We recommend that this case be brought specially to the notice of the directors of railway companies. If it could be proved that the birds had been poisoned whilst in the possession of their officials the companies would be liable for the loss.—Eds.]

DUBLIN POULTRY AND PIGEON SHOW.

Without dispute the Dublin Show has far surpassed any similar meeting yet held in Ireland—in fact, it must rank among the greatest poultry exhibitions in the kingdom. Carried out by a Committee, several of whom are among the most noted of our poultry amateurs, this Show was exceedingly good in its general arrangements, and the care bestowed on the specimens could not be excelled. The Exhibition Palace, in which the meeting took place, cannot be surpassed by any building for the purposes of a poultry show in regard to the equal diffusion of light, the ventilation, and the comfort of the visitors. Its being close to Dublin is also a feature of no little importance in securing a large attendance of all classes. Luckily the weather was propitious, and on the first day his Excellency the Lord Lieutenant, the Countess Spencer, Lady Clifton, and suite attended the meeting, and expressed themselves highly gratified. The public support on every day the Show remained open was most satisfactory, for although the avenues were wide and spacious, a glance from any of the galleries showed how abundantly filled with visitors was every department of the Show.

On entering, the Grey *Dorking* class first met the eye, and certainly a better display could not be wished for. Mr. John Martin, of Claines, Worcester, took precedence with his well-known Rose-combed pen, on this occasion much improved in condition as compared with that in which they were seen when exhibited at Bristol. He also took the third prize with a very good pen of single-combed birds, the hen in the latter pen being, however, somewhat small. The Hon. John Massy, who was second, had a very evenly-matched pair. In the class for Silver-Grey Dorkings we were quite disappointed, most of these birds being both very irregular in colour and markings. It is singular that though liberal prizes were offered for White Dorkings, only one pen was shown; that, however, was really good. In connection with the classes for *Cochins*, the names of Messrs. Lacy, Brierley, and Sichel are sufficient guarantee for first-rate quality in the respective varieties. Dark *Brahmas* were good, but for the most part quite overshown, Mr. Ansdell's second-prize pen especially so, whilst the Hon. Miss Douglas Pennant's third-prize pen was in admirable condition. Light Brahmas, though good, seem not to make any very rapid advance towards perfection, and therefore, with the exception of the prize pens, but little can be said in their favour. All three varieties of *Freneh* fowls were unusually good, and the La Flèche class was better than even at the largest of our English exhibitions. Of the *Spanish* class it is scarcely possible to speak more highly than it deserved. The Judges were so much impressed on this point as to suggest to the Committee the expediency of giving an additional prize, a request at once acceded to. After a long inspection the principal prize was awarded to Mr. Edward Jackson, of Wolverhampton, the remaining two prizes to the Hon. Miss Pennant, and certainly greater painstaking on the part of the Judges could not be desired, for a most unenviable task it must have been to decide among three pens closely on a par as regards perfection. It seemed to be a very general impression among visitors that had a different selection been made as to the four birds comprised in Miss Pennant's two pens, an easy triumph as regards the first position would have been secured in the Spanish class, whilst the additional third prize would have been even then not less desirable. A large entry of first-class *Hamburghs* by Mr. Beldon was a sufficient guarantee of the excellence of the prize pens, and we were glad to see some very superior specimens on view by other exhibitors. *Polands* were never shown more numerously nor so good, the Black White-crested class being extraordinarily perfect throughout. We believe this portion of the Show was the most attractive in the whole Exhibition. Of *Game* fowls there was a good show. Mr. Brierley, with the best four pens of English fowls of the day, managed to secure the principal prizes. Third came a pen that would be of no mean importance at most meetings. Malays, Black Hamburghs, and Scotch Greys secured prizes in the order named in the *Variety* class. This class was remarkable for the great variety of breeds on view, also for the perfection of most of them. Game *Bantams* were, almost without exception, good, but the majority were evidently suffering from long-continued exhibition. The Variety Bantam class was excellent, and an object of general attraction; Pekin and Black Bantams were the winners. Many Sebrights were also entered, but fell far short of what they were as exhibited in former years. *Geese* and *Turkeys* were examples of perfection in breeding, and included some of the finest hens for stock purposes we have seen for years. A numerous entry of fancy Waterfowl added much to the interest of the Show, Mandarins, the Carolinas, Kasarka Ducks, Whistling Ducks, Bahamas, and several other varieties being included in this most popular class.

The extraordinarily fine weather during the Dublin Show doubtless exercised a great influence on the attendance of visitors, which far surpassed the most sanguine expectations of the Acting Committee. Now that the Dublin Show is fairly launched upon popular favour, its continued and increased success may be depended upon.

PIGEONS.

(From a Correspondent.)

In Blue-pied Ponter cocks there were thirteen entries. Mr. Gresham's bird should have been in the front, and the highly commended bird of Mr. Horner second. Of Black-pied the cup bird well deserved his place. The second prize went to a grand bird though wanting in colour. Of Red-pied cocks there were nine entries, and in each award the prizes were well earned. Of Yellow cocks there were only two entries. For White the first prize went to a grand bird, Mr. Gresham's bird being neater and narrow in girth, though wanting in crop. Had this bird been trained to show himself he would have been difficult to beat. In this class were thirteen entries. In the class for any other colour, a wonderful Mealy bird carried off the first prize. The second and third were well held. Blue-pied hens were a grand class of eight entries. The cup bird was closely pressed by admirable birds. Black-pied hens were a good class. The colour and markings of each specimen were above the average, and the awards well made. The first prize went to a faultless bird. In Red-pied hens the first-prize bird was bad in colour, good in size and limb. The second and third were fine in colour but too small. Mr. Horner's bird should have been in the prize list. There were five entries. Of Yellow-pied hens there were only three entries, and the honours were well held. White hens were a very good class of ten entries. The principal prizes went to birds of more than usual merit. Hens of any other colour were a poor class.

Of Carrier cocks there was a grand display, consisting of eleven pens. A bird of Mr. Horner's should have been in the list. Mr. Ord's bird should have been placed forward. Of Black Carrier hens there were three entries, the cup going to a grand bird good in all points. In Dun Carrier cocks the cup went to a bird of great merit, closely run by Mr. Horner and Mr. Whealand. Of hens there were seven entries. In Blue Carrier cocks the second-prize bird should have been first. This was a poor class. The Blue hens were better. This colour requires to be cultivated. The class for the best pair of Black Carriers of 1871 formed a grand display, and the positions were well maintained. In the class for the best pair of any other colour there were five entries, and the cup birds were worthy of their position. Mr. Hodgkinson's birds were good.

Almond Tumblers were a fair lot. The cup and third-prize birds were well placed. In the class for Tumblers of any other colour Yellow Agates were first, Black Beards second, and Red Tumblers third. A good pair of Mottles were left out for reasons best known to the Judges.

Black Barbs formed a wonderful class of nine entries. Here the Manchester birds had to take the third place. Mr. W. B Van Haansbergen's birds ought to have been forward; they are a grand pair of warriors. In Barbs of 1871 there were nine entries, Mr. Montgomery again winning. Mr. Whealand's and Mr. Wallace's birds were deserving of their positions.

In the class for Red or Yellow Jacobins there was a most evident miscarriage of judgment, the cup going to a pair of Yellows unevenly matched in colour, with white throats. Though they are the Scotch fancy English fanciers would discountenance them. Mr. Thompson's birds, as Yellows, were far preferable. The second-prize were Yellows of little merit; the third-prize pair were Reds of doubtful sex. Mr. Waitt's best birds, left out altogether, ought to have been in the prize list. This was the largest class in the Pigeon varieties, and some wonderful spe-

cimens were sent for competition. There were sixteen entries. Of Jacobins any other colour there were ten entries ; nine pairs were Blacks, one pair Whites. Mr. Waitt's Blacks were first-class in all points, and their line of marking distinct. These were unnoticed, one of the birds having had a few feathers abstracted from over the eye. The first-prize cock bird was not decided in chain, but good in other respects. Third came a neat pair, small, and well up to the average. The second-prize birds were good in colour and small, but badly matched. An exquisite class.

Fantails were good. There were nine pens. The first prize went to small birds, bad in tails, but possessed of that fine tremulous motion so much regarded by northern fanciers. They were in bad feather. The second-prize birds were far better in all respects. The third prize went to Blues, good in all points. Mr. Martin's two grand pairs were passed over.

Of Nuns the first-prize birds were good, but Mr. Watts's birds were preferable, being more even in the flights, and well saddled and cut. The third-prize were bad Yellows, wanting in hoods.

Of Black Trumpeters there were some extraordinary specimens. The cup, first, and second were an easy victory. In the class for Trumpeters, any other colour, Mr. Horner's champion birds were to the front, with a wonderfully fine pair second. Two better classes of Trumpeters were never before seen.

In Turbits Blues were first and second, and Yellows third. Mr. P. H. Jones's Reds should have been first, with Mr. Fielding's Reds and Mr. Horner's Blacks to follow.

Foreign Owls were a good class, the Rochdale birds enjoying their usual reputation, closely pursued by a grand pair of Blues, which were third. In English Owls bad Blues with white rumps were first. Blues were second. Third came semi-powdered Blues. Mr. P. H. Jones and Mr. Kemp ought to have been in the prize list.

For Magpies the first prize went to a pair of Blacks, the second to Reds of grand colour, and deserving of first honours, the third to fair Yellows.

In Dragoons, Blues and Yellows were first and extra third. The second-prize Yellows were good. Those which took the third prize appeared too heavy in eye and wattle for the Birmingham standard. There were eleven entries.

Of Antwerps there were seven pairs. A poor class.

In the "Any other variety" class good Red Swallows were first, Black Priests second, and White Tumblers third.

In the Selling class, Fantails, Barbs, and Black Turbits took the prizes. A good hen Barb in a highly commended pen was at once claimed, and a pair of Reds found a ready purchaser.

The cup for the best collection of four pairs of Pigeons, exclusive of Pouters, Carriers, and Tumblers, was taken with Black Turbits, White Jacobins, White Fantails, and Mottled Trumpeters ; the second prize with Black Trumpeters, Black Barbs, Red Jacobins, and White Fantails ; the third with Black Jacobins, Black Barbs, Yellow Turbits, and White Fantails.

KENDAL POULTRY SHOW.

This Show has long been noted for the liberal support it receives from the surrounding district, and embraces specimens from almost every breeder of note in the kingdom. A very commodious mill affords ample room for the Exhibition, and as a rule there is a very satisfactory attendance of sightseers.

The *Game* fowls as classes have rarely been excelled, though a somewhat large entry of Mr. Charles Brierley's best birds monopolised the principal prizes in this division of the Show. It is rare that there is so perfect and even an entry of *Hamburghs* at any show as that made at Kendal. *Dorkings* formed heavy and very good classes, and the prizes were widely distributed. *Cochins* were mostly from our principal yards, and embraced almost all the successful pens of the season. Want of condition in many instances was deplorably manifest, from the specimens having passed of late more of their time on the railway than the hen-roost. The display of Black *Spanish* fowls was good ; and the same remark is equally deserved by the Dark *Brahmas*, but the Light Brahma entry was very limited indeed. A very heavy Selling class brought forward an excellent entry, and consequently proved a profitable feature of the Show, a considerable number of pens changing owners. The show of *Geese*, *Turkeys*, and *Ducks* was large, and in most varieties very good.

There was a grand display of *Pigeons*—in fact, one of the best local shows seen for some years past. Antwerps and Carriers were especially worthy of favourable mention; nor were the Owls, Barbs, and Tumblers less deserving. The Pigeons were arranged sadly too high by many feet to be properly seen by those desirous of close inspection.

There was a good attendance of visitors, and the management of the poultry was excellent. The prize list was given at page 68.

The Canary a Mocking Bird.—Noticing in your Journal of January 18th the account of a Canary which learnt an air from a hand-organ, it may interest some of your readers if I mention another instance of the Canary's aptitude for acquiring notes dissimilar to its own. I had a Belgian bird with a song of rare excellence, which he preserved for two seasons. At the same time I had several Avadevats, which, tiny as they are, have a lovely song, tiny like themselves, but most perfect in sweetness. To my sorrow the third season my Canary quite lost his song, although in perfect health. One day, to my surprise, as I sat in a room adjoining that where the birds were, I heard the Avadevats' song most perfect, but louder than possible for the minute singer, and this explained the Canary's loss of song. He had been studying the notes of his small companions, and delighted with his success with the song of one Avadevat, it was most amusing to hear him practising the variations in the notes of the others, which he also accomplished. I was at last obliged to separate them, as after giving all his attention to acquire the foreign song, he proceeded to blend it with his own, thus spoiling both.—R. M., *Lymington*.

BARROW POULTRY SHOW.

This was held on January 26th and 27th. The following awards were made :—

Game.—*Cock.*—1 and 2, C. W. Brierley, Middleton. 3, W. Boyes, Beverley. *hc*, R. B. Hudson, Ulverston; J. Forsyth, Wolverhampton; G. Fletcher, Didsbury. *Cockerel.*—Cup and 2, C. W. Brierley. *hc*, J. Bowness, Newchurch. *c*, J. Mashiter, Ulverston. *Pullet.*—1, W. Boulton, Dalton-in-Furness. 2, C. W. Brierley. *hc*, T. Mason, Green Ayre; C. W. Brierley; W. R. Ormandy, Barrow; W. Bearpark; J. Bowness. *c*, G. C. Wilson.

Game (Black-breasted and other Reds).—Cup and 2, C. W. Brierley. *hc*, W. Boyes; T. Mason; W. Boulton; J. W. Brockbank, Kirksanton; J. Bowness; J. Brough. *Duckwings and other Greys and Blues.*—1, C. W. Brierley. 2, W. Boyes. *c*, L. Casson, Ulverston.

Cochin-China (Cinnamon and Buff).—1, G. Fletcher. 2, Mrs. Wilkin, Bootle. *hc*, E. Fearon, Whitehaven; C. Sidgwick. *White.*—1, J. Sichel. 2, J. & T. Weeks, Bootle. *hc*, E. Fearon. *Cock.*—Cup, J. Sichel

Brahma Pootra.—1, T. F. Anadell. 2, Dr. Holmes, Whitecotes, Chesterfield. *hc*, J. W. Brockbank.

Hamburghs (Golden-spangled).—Cup and 2, J. Buckley, Taunton, Ashton-under-Lyne. *Silver-spangled.*—1, G. Mitchell, Keighley. 2, Ashton & Booth, Mottram.

Game Bantams.—*Cock.*—1, R. Tyson, Barrow. 2, T. Sharples, Rawtenstall. *hc*, T. Barker, Burnley; J. W. Morris. *c*, G. Maples, jun., Wavertree. *Any other Variety.*—1, J. W. Brockbank. 2 and *hc*, Bellingham & Gill, Burnley. *c*, A. Ainslie, Ulverston.

Bantams (Black or Brown Reds).—1, J. W. Morris. 2, T. Sharples. *hc*, T. Barker; G. Maples, jun.; J. Mashiter.

Bantams (Any other Variety except Game).—1, M. Leno. 2, W. H. Robinson, Long Lee, Keighley. *hc*, R. & H. Ashton, Mottram. *c*, R. Gladstone, jun. Broad Green, Liverpool; T. Lumb, Rochdale.

Ducks (Rouen).—1, J. White, Whitley, Netherton. 2, J. Banks, Kendal. *hc*, H. B. Smith, Broughton, Preston; G. Porter. *East Indian.*—1 and 2, G. S. Sainsbury, Devizes. *hc* and *c*, S. Burn, Whitby. *Any other Variety.*—1, C. W. Brierley. 2, H. B. Smith. *hc*, M. Leno (3); H. B. Smith

Any other Variety.—1, Mrs. J. Cross, Appleby Vicarage, Brigg. 2, W. Hill, Heaton Moor, Stockport. *hc*, Mrs. Wilkin.

Selling Class (Poultry or Pigeons).—1, T. Thompson, Lancaster (Black Hamburghs). 2, J. Nicholson, jun., Carlisle (Hamburghs). 3, R. B. Hudson. 4, J. Mashiter (White Cochin-). *hc*, J. Gelderd, Kendal (Wild Ducks); J. H. Wilson, St. Bees ; J. Mashiter (Game); W. Grice, Bootle.

PIGEONS.

Carriers.—1, E. Horner, Harewood, Leeds. 2, E. C. Stretch, Ormskirk. *hc*, R. Lomas, Rampside; J. & W. Towerson, Egremont; H. Yardley, Birmingham.

Pouters.—1 and 2, E. Horner. *hc*, H. Yardley.

Tumblers.—1, J. & W. Towerson. 2, E. Horner. *hc*, H. Yardley.

Jacobins.—1, E. Horner. 2, F. Waitt, King's Heath, Birmingham. *hc*, J. and W. Towerson; H. Yardley

Antwerps.—1 and 2, C. F. Copeman, Birmingham. *hc*, H. Yardley.

Barbs.—1, H. Yardley. 2, W. Jackson, Bolton-le-Sands. *hc*, E. Horner.

Turbits.—1, E. Horner. 2, H. Yardley. *hc*, J. & W. Towerson.

Owls.—1, E. Horner. 2, J. & W. Towerson. *hc*, W. Lumb.

Fantails.—1, J. F. Loversidge, Newark. 2, E. Horner. *hc*, T. Imrie, Ayr; H. Yardley; J. W. Edge, Erdington.

Dragoons.—1 and 2, F. Graham, Birkenhead. *hc*, W. Hill.

Trumpeters.—1, J. & W. Towerson. 2 and *hc*, E. Horner.

Nuns.—1 and *hc*, J. Fisher, Barrow. 2, H. Yardley.

Any other Variety.—1, J. & W. Towerson. 2, H. Yardley. *hc*, T. Imrie; E. Horner.

CANARIES.

Belgian (Yellow).—1, J. Wood, Barrow. 2, J. N. Harrison, Belpar. *Buff.*—1, J. Wood. 2, W. Jones, Ulverston.

Mule.—1, R. Hawman, Middlesbrough. 2, J. Goode, Leicester. *hc*, J. N. Harrison; Stephens & Leek, Middlesbrough.

Piebald (Yellow or Buff).—1, R. Hawman. 2, J. N. Harrison. *hc*, Stephens and Leek; J. Clemiuson, Darlington.

Lizard (Gold or Silver-spangled).—1, J. N. Harrison. 2 and *hc*, J. Taylor, Middlesbrough.

Common Yellow.—1, W. Watson, jun. 2, J Hill. *hc*, Stephens & Leek.

Goldfinch.—1 and *hc*, J. N. Harrison. 2, J. Goode.

Rabbits (Tame).—1 and 2, T. E. Terry, Tong. *hc*, T. E. Terry; A. L. Peace, Thorne ; J. H. Wilson.

Judges.—*Poultry :* Mr. R. Teebay, Fulwood, Preston. *Pigeons and Canaries :* Mr. J. Douglas, Clumber, Worksop.

LOWESTOFT POULTRY SHOW.

The fifth annual Show was held in the Town Hall, Lowestoft, on the 24th and 25th of January. The building, which is small but handsome, was filled to repletion, and many entries which were made late had to be returned, owing to want of room. The pens were of a most substantial kind, formed on three sides of wood and the front of rod iron. The sliding doors admitted of easy access for the handling of the specimens—a point not always

sufficiently attended to. Each pen was scraped out and re-sanded every morning, and perches provided for the night. The regulations were very complete, and carried out with the greatest precision. The Honorary Secretary and the principal members of the Committee were in constant attendance, and the financial results of the Show were very satisfactory.

The first class for poultry was *Game;* the cup-winners were Brown Reds, and the second prize went to Duckwings. The former were a very even pen, and the second contained a most perfect pullet, but the cockerel had lost a sickle feather. *Dorkings* were a fair class. The cup cock was a large and perfect bird, but the hen was not so good as the second-prize one, which was, however, shown with a cock which in colour partook greatly of the points of a Silver-Grey. In *Spanish* the cup went to a pen of chickens, the cockerel being a well-developed bird and the pullet extremely fine, although the hen in the second-prize pen was far heavier in face and drop. The winning *Cochins* were Buff. Those in the cup pen of Lady Gwyder were very true to colour and very large, the hen being a perfect picture. The same lady won the cup for *Brahmas* with a grand pen composed of a cockerel and hen, the latter exquisite in marking, the lacing working well up to the throat. The competition in this class was keen, there was not a pen that did not contain one or more good birds. There were four classes for *Hamburghs,* and the cup was won by an excellent pen of Golden-spangled, in which class the Hon. Secretary showed several excellent pens, but not for competition. In Golden-pencilled there was but one really good pen, the pullet in which was most perfectly pencilled. Silver-pencils were a failure both in numbers and quality, but the two winning pens of Silver-spangled were of high quality. The first-prize cock was too white in face for a young bird. In the *Variety* class, Silver Polands were first and White-crested Blacks second. Sultans, Silkies, and Polands were highly commended. The Selling classes for both sexes were well filled, and very good Silver-spangled won in each case. There were eighteen pens of Game *Bantams.* The first prize and cup for that section were awarded to Piles, this pen being of extraordinary quality for that colour and in the best condition. Second came Black Reds, the cockerel not in the highest order, and the hen very neat but a little squirrel-tailed; the third an old pen, splendid in colour but rather heavily feathered. In the next class of Bantams a pen of Silver Sebrights of great purity of ground colour and without a single speck on the tails, except the proper lacing, were first, very good Blacks second, and Whites third. *Ducks* in neither class were of particular note, with the exception of a pair of Ruddy Shells, which were too late for competition.

The competition in *Pigeons* was severe, a cup for the greatest number of points being given. Mr. Hawley, out of twenty-three entries, took four first prizes, five second prizes, and eleven high commendations. Mr. Waddington followed with twelve entries and one first prize, two second prizes, and five high commendations; and Mr. Jones with fourteen entries and one first prize, two second prizes, and five high commendations. Carriers were first on the list, both classes of adult birds being good and the competition close. The first-prize Black cock was good in size, style, and carriage, had a good beak-wattle, but was not so good in eye as the second-prize bird, but the first-prize hen was the best in the class. The young class contained some most promising birds of both sexes and colours. Mr. Wren here also sent thirteen specimens of excellent birds, but not for competition. In Pouters the first-prize cock was Blue and the second White; the former 19½ and 7 inches, and the latter 18¼ and 7 inches. Of the hens the first was Red, 19 inches by 7¼, and the second Blue, 17¾ inches by 7, although the latter bird had the best carriage in the Show. Shortfaced Tumblers were good. Almonds were both first and second. It is seldom that so good a collection of Longfaces is seen. Several of the pens were perfect in marking and free from trimming. Black Balds were first and Black Mottles second. Barbs, both old and young, were moderate in quality. The best pair in the first-named class was left out on account of their eyes being quite made up. Fantails were a good class. In style and carriage the first-prize pair was perfect; and although the birds were small, they were not nearly so small as the second-prize pair. Antwerps were a most interesting class—every variety of head, from the Dragoon to the common Snipe and Barb, every colour of eye, and some even with a portion of feather on the leg. The first prize went to a sound-coloured pair of Duns with long heads but very short thick beaks, the second to very short-headed Red Chequers, and the third to a very handsome pair of Longfaced Blue Chequers. In the Variety class, though it was large, Mr. Jones won very easily with Foreign Owls, the second prize going to Yellow Dragoons, the third to Ice, and the fourth to Nuns.

GAME (Any variety)—Cup and 2, S. Matthew, Stowmarket (Black-breasted Reds and Duckwings). Local Prize, C. Sayer, Lowestoft (Black Reds) *hc*, H. E. Martin, Sculthorpe (Brown Reds); R. Postle, Gazeley, Newmarket (Black Reds). *c*, R. Hall, Cambridge (2)

DORKINGS (Any variety).—Cup, F. Parlett, Great Baddow (Coloured). 2, L. (Patton, Hillmore, Taunton (Coloured). Local Prize, L. J. Feto, Lowestoft Coloured). *hc*, H. Lingwood, Barking, Needham Market (Coloured); Mrs. G. Clarke, Long Sutton.

SPANISH.—Cup, — Nicholls, Bros, Camberwell. 2, W. Jackson, Blakedown, Kidderminster. Local Prize, W. Saunders, Lowestoft. *hc*, P. H. Jones, Fulham; T. C & E. Newbit, Epworth.

COCHIN-CHINA (Any variety).—Cup, Lady Gwyder, Stoke Park, Ipswich. 2, H. Lingwood (Partridge). Local Prize, J. T. Woods, Oulton, Lowestoft (White). *hc*, H. Lingwood (Buff); J. Long, Plymouth (Buff). *c*, R. S. S. Woodgate, Pembury, Tonbridge Wells (White).

BRAHMA POOTRA (Any variety).—Cup, Lady Gwyder. 2, Horace Lingwood, Creeting (Dark). Local Prize, A. Page, Oulton, Lowestoft (Dark). *hc*, A. Page (Dark); Rev. J. Richardson (Dark); T. F. Ansdell, Cowley Mount, St. Helen's. *c*, W. Hughes, Oakham; Mrs. Bishop, Bungay (Light); J. Watts (Dark.)

HAMBURGHS (Golden-pencilled).—1, R. B. Parker, Ipswich. 2 and *hc*, W. K. Tickner, Ipswich. Local Prize, W. H Ashford, Oulton, Lowestoft.

HAMBURGHS (Silver-pencilled).—1, D. C. Packard, Macton. Local Prize, W. Saunders, Lowestoft.

HAMBURGHS (Golden-spangled).—1 and Cup, J. B. Lakeman, Ipswich. 2, R. H. Ashton, Mottram. Local Prize, Mrs. Deaton, Lowestoft. *hc*, T. May, Wolverhampton; W. K. Tickner.

HAMBURGHS (Silver-spangled).—1, Ashton & Booth, Mottram. 2 and Local Prize, J. B. Bly, Lowestoft.

ANY OTHER VARIETY (Except Bantams).—1, W. K. Patrick (Polands). 2, W. Jackson, Blakedown, Kidderminster (Polish). Local Prize, J. Lung, Lowestoft (Houdan). *hc*, Mrs. J. Cross, Appleby Vicarage, Brigg (Creve-Cœurs); E. P. Youell, Yarmouth (Black Hamburghs); W. H. Tomlinson, Newark (Sultans); R. S. S. Woodgate (Silkies); T. Waddington (Golden Polands).

SELLING CLASS.—*Cock, Cockerel, or Brood.*—1, J. B. Bly (Silver-spangled Hamburghs). 2, A. Page (Dark Brahma). 3, T. C. & E. Newbitt. Local Prize, C. Denton (Brahma). *hc*, J. Taylor, Lowestoft (Golden-pencilled Hamburgh); W. K. Patrick (Poland); C. Denton; H. E. Martin, Gedney (Brown Red Game); F. T. Gordon, Newcastle, Staffordshire (Game); Hon. Mrs. Paget, Hoxne (Brown Red Game). *c*, W. Burrows, Diss (Aylesbury Drake); T. M. Derry (Light Brahma and Partridge Cochin); M. Leco (Light Brahma); F. Bowman, Lowestoft (Duckwing Game); R. B. Parker (Golden-pencilled Hamburghs). *Hens, Pullets, or Ducks.*—1, J. B. Bly (Silver-spangled Hamburghs). 2, H. Griss (Spanish). Local Prize, C. Denton (Golden-spangled Hamburghs). *hc*, Rev. W. F. Dixon, Oby Rectory (Black Red Game); C. Denton (Golden-spangled Hamburghs); W. Saunders (Spanish); — Nicholls, Bros. (Spanish). *c*, J. B. Bly (Silver-spangled Hamburghs.)

GAME BANTAMS (Any variety)—Cup, T. C. & E. Newbitt. 2, W. Adams, Ipswich (Black Reds). 3, W. Robins (Black Reds). Local Prize, J. F. S. L. Barber, Lowestoft (Black Reds). *hc*, J. Long (Brown Red); W. Adams (Duckwing); Hon. Mrs. Paget (Duckwings); T. C. & E. Newbitt. *c*, T. Page (Black Reds); H. W. Wallace (Black Reds).

BANTAMS (Any other variety).—1, Mrs. J. M. Proctor (Laced). 2 and 3, Rev. F. Tearle, Gazeley (Laced). Local Prize, Mrs. G. Clarke (Black); C. Reed, Cambridge (White); R. H. Ashton (Black); Rev. G. F. Hodson, North Petherton; M. Leco (Laced); T. Waddington (Gold-laced and Pekin). *c*, Mrs. Balch (Japanese.)

DUCKS (Aylesbury).—1 and 3, F. B. Pe'is, Kessingland.

DUCKS (Any other variety).—1, Rev. J. Richardson (East Indian). 2, A. Page (Rouen). Local Prize, T. Tack (Montevideo). *hc*, M. Leco, Markyate Street (Carolina); R. H. Ashton (Mandarin); Rev. J. Richardson (Carolina); R. S. S. Woodgate.

EXTRA CLASS.—*hc*, W. V. Barnard (Peafowls.)

PIGEONS.

CARRIERS.—*Cock.*—1, E. Walker, Leicester. 2, T. Waddington, Feniscowles, Blackburn. *hc*, F. W. Metcalfe, Cambridge; T. Waddington; S. Holroyd, Hunmanby, Oldham. Jun.: P. H. Jones. *Hen.*—1, T. Waddington. 2, E. Walker. *hc*, F. W. Metcalfe; T. Waddington.

CARRIERS (Any variety).—*Young.*—1, E. Walker. 2, J. Hawley. 3, H. Thorlow. *hc*, S. Holroyd; C. H. Clarke, Old Scotnton, Nottingham; F. W. Metcalfe; E. Walker; E. Edmonds, Yarmouth.

POUTERS.—*Cock.*—1 and *hc*, J. Hawley. Bradford. 2, H. Thurlow, Burnham Market. *vhc*, W. Nottage, Northampton. *c*, J. Hawley. P. H. Jones (2); T. Waddington. *c*, W. Nottage. *Hens.*—1, J. Hawley. 2, P. H. Jones. *hc*, J. Hawley; T. Waddington. *c*, W. Nottage.

TUMBLERS (Short-faced).—1 and *hc*, J. Hawley. 2, P. H. Jones. *c*, T. Waddington, Feniscowles.

TUMBLERS (Any other variety).—1 and 2, J. Hawley. Local Prize, C. Cowles, Lowestoft. *hc*, J. Hawley; J. Lincoln (Yellow Balds); W. Simmons (Yellow Beards)

BARBS.—1, E. Walker. 2, J. Hawley. Local Prize, D. Bedford Lowestoft. *hc*, W. Minard, Dover; P. H. Jones. *Young.*—1, E. Walker. 2, T. Waddington. *hc*, J. Hawley. *c*, P. H. Jones.

FANTAILS.—1, J. S. Loversidge. 2, J. Hawley. *hc*, T. Waddington; P. H. Jones; A. A. Vander Meersch.

ANTWERPS (Any variety).—1, J. W. Collinson, Halifax. 2, J. Hawley. Local Prize, D. Bedford. *hc*, J. Hawley; W. Mioson; W. H. Mitchell; — Holroyd.

ANY OTHER VARIETY.—1, P. H. Jones (Owls). 2, G. S. Clements (Yellow Dragoons). 3, T. Waddington (Ice). 4, J. Watkins (Black Nuns). Local Prize, A. W. Wren (Red Dragoons). *hc*, J. Hawley (Turbits and Owls); H. Thurlow (Blue Dragoons); A. W. Wren (Yellow and Red Dragoons); W. Nottage; R. Craoe, jun. (Blue Dragoons); W. Minson; P. H. Jones (Trumpeters); A. A. Vander Meersch (Black Magpies). *c*, Mrs. Bishop (Blue Runts.)

SELLING CLASS.—1, W. Minson (Barbs). 2, H. Thorlow (Dun Carriers). Local Prize, A. W. Wren (Yellow Dragoons). *hc*, J. Hawley; A. W. Wren (Yellow Dragoons); P. H. Jones; E. Edmonds (Carriers.)

JUDGES.—Rev. T. L. Fellowes, Norwich; Mr. E. Hutton, Pudsey, near Leeds.

DRAGOONS AND ANTWERPS.

I TAKE a great interest in the breeding of both Dragoons and Antwerps, and I venture to endorse the remark you make about those two important classes of Pigeons.

Dragoons, as you say, are increasingly popular; it is, therefore, all the more necessary that breeders should have before them a fixed standard of excellence at which to aim; that decided, all breeders would keep a keen eye upon the goal, and our judges would not only be spared much indecision, but much criticism.

When Mr. F. Graham opened the question I hoped to have seen a greater interest manifested, but suppose that, as the Dragoons are a breed that has hitherto received but here and there a notice by the various show committees, there are not many large breeders. The difference of opinion seems not to be in regard to the build of the bird's body, which, by-the-by, I think is mostly rather too heavy, but as respects the beak, wattle, and eye. Is not the "stout" beak, advocated by Mr.

Graham, the opposite error of the "spindle" beak he condemns? Does not a medium add gracefulness to the birds? Is not the "heavily-wattled," so often used in connection with them, out of character? Do they not look more graceful without it—more like a distinct breed, which I think is what we ought to aim at?

With respect to Antwerps—a class that should afford considerably more amusement to society than they do, by exercising their special powers of flight—they, too, seem to have drifted from their old moorings, and, as too often seen at our shows, uncertainty prevails. It appears to me that the most simple way to form a standard would be for the Committees of our two largest shows—namely, those at the Crystal Palace and Birmingham—to exchange opinions, and publish their decisions in this Journal. Other committees would be certain to follow in the wake.—WILLIAM MINSON, *St. Ives*.

PIGEONS GOING LIGHT.

I HAVE had several of my Pigeons in this condition, and I have effectually cured them by feeding them on toasted bread and ale, keeping them warm, and giving them a little canary seed to peck at. A friend of mine has also had several cases amongst his Antwerps; he has fed the birds on bread crumbs, and given them milk to drink. I know of another case of a Carrier fancier who had his birds light all the summer, and was unable to breed from them. He was administering cod liver oil to them night and morning, and hoped in a short time to have his birds all right again. A friend at once tried the oil. He says it is the finest thing he ever tried; the worst result is that the oil greases the birds so that they are not fit to go into a show pen until they have moulted.—H. ALLSOP.

QUEENS LEAVING THEIR HIVES.

HAD the question been asked me before last spring, Do adult queens leave their hives except with swarms? I should have readily answered, Decidedly not. Such a proceeding is quite contrary to their instincts. I will, however, narrate the only exception to the rule I have yet met with during the course of my experience.

Very early in the past year a friend at a distance forwarded me his strongest black colony, which I had promised to Italianise. On arrival it proved to be both populous and well stored. To accomplish the object in view I took advantage of the first mild day to drive the black stock and dethrone its queen. I then made an examination of my weakest hive, which towards the close of the season had been but a queenless nucleus, to which I had safely introduced an imported queen, unexpectedly received at the end of October from the late Mr. Woodbury, to whom I cannot allude without joining in the general expression of sorrow at the great blank which has been caused by his removal. I had never the good fortune to meet Mr. Woodbury, but from a constant correspondence carried on for some eleven years, and intensified from the circumstance of our apiaries having been simultaneously swept with foul brood, I cannot look back on the kind sympathy, happy suggestions, and sound advice his ready pen at all times so fraternally afforded, without expressing my great regard for his memory.

The four frames of the nucleus were transferred to a Stewarton breeding-box, and the readiest mode of feeding was setting upon it a good super honeycomb, and on now making an examination I found the bees had vacated entirely the lower box, had thinned-down the central combs, and that beautifully-banded young bees and brood in all stages abounded in the octagon super. The queen herself had attained most matronly proportions since the preceding fall, and was markedly the highest-coloured and most beautiful I ever beheld. At dusk the same evening I transferred this super to the black colony, and on drawing the intervening slides had the satisfaction to hear a pleasant hum set up, and the queen, missing, commotion subside in the black colony. On the following morning I found the yellow-jackets freely fraternising with the blacks, and as the weather was too cold to re-drive the stock to satisfy myself as to the safety of the queen, I had the further satisfaction, two or three days afterwards, of seeing her majesty freely perambulating the combs in front of one of the windows.

A good many weeks passed over; on genial days fine flights of nicely-banded Italians emerged, till late on a very sultry afternoon towards the end of April, when visiting the apiary, my attention was attracted to this particular colony by a most unwonted sound. Could it be possible?—drones in April! when with us they rarely appear before the first days of June, and in *full* hives too! but sure enough there they were in abundance, the air reverberating with their pleasant hum, among quite a little cloud of gay youngsters of the other sex. While stooping over the landing-board to admire the very distinct and bright banding of the males, quite in keeping with the unusual fineness of the high-coloured workers, to complete the family group, to my utter amaze, who should appear at the entrance but the royal mother herself, no shy slim princess on matrimonial tour intent, but my beautiful and matronly queen. She evaded my grasp on my endeavouring to clutch her, as I hastily supposed, in her mad career to abandon her hive, and majestically soared away. Transfixed, I pulled out my watch; ten seconds did not elapse till she alighted on the board and re-entered the hive as composedly as if an afternoon's airing with royalty might be an everyday matter.

I cannot account for the phenomenon on any other ground than that possibly the queen may have for the first time descended from the upper to the lower breeding-box, and when there was impelled in the crowd still onwards to the entrance, by the hubbub and excitement of the moment, mistaking the exodus of young bees and drones for a swarm, and, not discovering her mistake till fairly on the wing, she then quietly returned.—A RENFREWSHIRE BEE-KEEPER.

THE NORTHAMPTON SOCIETY'S POULTRY SHOW.—The third annual Show is to be held on the 6th and 7th of March. The schedule indicates a progressive spirit, the chief feature being to give all sorts of breeders a chance. The prizes are liberal considering the number of classes in the schedule, and for a young society; but it is started on a good basis, and managed by men who evidently understand what they are about. Seven pieces of plate and £100 for prizes are not bad for a third show, when it is known that the whole, with the exception of one piece of plate, is offered by the Committee themselves. Placed in the centre of England, with good railway accommodation, Northampton should be well patronised by all breeders.—H. THORNYCROFT.

TO MAKE A VARNISH THAT WILL IMITATE GROUND GLASS.—Mr. J. Garratt has favoured us with the following:—To make a varnish to imitate ground glass dissolve 90 grains of sandarac and 20 grains of mastic in 2 ozs. of washed methylated ether, and add, in small quantities, a sufficiency of benzine to make it dry, with a suitable grain—too little making the varnish too transparent, and excess making it crapey. The quantity of benzine required depends upon its quality—from half an ounce to 1½ oz. or even more; but the best results are got with a medium quality. It is important to use washed ether, free from spirit.—(*British Journal of Photography.*)

OUR LETTER BOX.

BIRMINGHAM CUP DORKING COCKEREL.—I think it right to state that the Dorkings Mr. J. B. Saunders advertised in your Journal as being bred from Arkwright's cup cockerel of 1870, at Birmingham, are incorrect; the cup cockerel of that year was bred by me, and was sold there at the show for £9 9s. to a gentleman who still has him.—J. J. WALLER, *Mint House, Kendal*.

SUBSCRIBERS TO THE WOLVERHAMPTON LIGHT BRAHMA CUPS.—The following ladies and gentlemen have subscribed to the Wolverhampton Light Brahma cups:—Mrs. A. Williamson, 10s. 6d.; Miss Hales, 10s. 6d.; Mrs. Turner Turner, 10s. 6d.; Messrs. Fares, 10s. 6d.; F. Crook, 10s. 6d.; A. O. Worthington, 10s. 6d.; J. Bloodworth, 10s. 6d.; H. M. Maynard, £1 1s.; J. R. Rodbard, £1 1s.; J. Beach, £1; Capt. Downman, £1 1s.; W. T. Storer the remainder, unless some other lady or gentleman will kindly assist.—W. T. STORER, *Shott Green, Brewood, Stafford*.

MRS. CLARKE (*W. Corbet.*).—Proceed against her husband in the County Court.

DUBLIN SHOW.—Col. Hassard, R.E. took the Peristeronic Society's cup, as well as the first prize, for the best pair of Carriers of "Any other Colour." For single cocks of La Flèche Mr. J. C. Cooper was 1st, Mr. G. A. Stephens 2nd.

PLYMOUTH POULTRY SHOW (*Journal*).—We decline inserting any more letters on this Exhibition, hoping that this year there may be fewer causes of complaint.

MINORCAS (*R. W.*).—The original Minorcas were black, and almost all the birds shown as birds of this breed of late years have been only degenerate Spanish. Their home was Devonshire, and many years ago when we tried that county to get some, we had answers that everywhere the breed was lost. The last person who had them was a clergyman, and he had to cross with Spanish in order to keep a semblance of the breed. We have not seen a Minorca for thirty years. We are, however, glad to hear it has been only a misfortune and that they still exist.

HOUDANS FEATHER-EATING (*Houdan*).—We have never met with a case of feather-eating in Houdans except at the end of the summer, and when they have been kept in confinement. We cannot account for it in this case; but as you say one hen is spoiling your walk of fowls, you should immediately remove her before the others learn the habit. You should have done so at once. Fowls are like children at school, there is nothing one will not do that others will not copy. Feeding has something to do with it, and we do not approve of your dietary. Potatoes and Indian meal are bad feeding, oats are bad. Change it. Let the birds have morning and night some ground oats slaked with water, and barley for a mid-day meal. Give them all the table scraps you have, but if they have a good grass run they can do without cabbage leaves. They do not need the bullock's liver. It is sometimes given to birds in confinement, but it is hardly necessary. Continue the supply of gravel and bricklayers' rubbish. We do not think you can keep the Game Bantams satisfactorily in the way you propose.

SHELL-LESS EGGS (*G. P. C.*).—Your fowls are out of order. Alter their food for ground oats. If they are not to be had give oatmeal, and supply them with bricklayers' rubbish made up of old mortar, ceilings, &c.; they will pick among it and find material for the shell. They will benefit greatly by having thrown to them every day some large sods of growing grass cut with plenty of fresh earth.

FATTENING DUCKS (*J. C. L. R.*).—You cannot do better than continue feeding with barleymeal, putting it in water. We gather from your letter they are at Iberty; they will not, when ducklings, fatten unless they are confined. All you give goes to growth, as it would do in a healthy boy. The Ducks that are fattened in Buckinghamshire and Oxfordshire are kept up, and besides oatmeal and bran have meat given to them. As soon as they are old enough, when about half grown, they are very fond of oats put in a shallow vessel, the bottom of which is covered with a sod of grass, and then filled with water to the brim. They will eat this when they refuse other food. It is unusually early for a Game Bantam to lay at five months.

COCHIN-CHINA HENS LAYING IN WINTER (*J. S.*).—Yours is a very pleasing exception, and we congratulate you on it. We have ourselves some hundreds of hens and pullets. We have as yet only eggs from the latter. They are as well cared for and as well fed as any birds in the world, but they have no stimulating food, and no meat. Will you kindly inform us how yours are fed? Although we have half a century of experience, we are more than ready and happy to learn.

MALT DUST AS POULTRY FOOD (*W. L.*).—The eggs will be fertile within a week, if not earlier. Fowls are very fond of malt dust, and given moderately it is good food, but it communicates its flavour to the eggs.

BLACK SPANISH WITH RED FEATHERS (*Red Feather*).—It is no proof of impurity or inferiority of breed if a Spanish cock shows a red feather. Such come mostly in the hackle or saddle. All black-feathered cocks are prone to the same fault, and it often increases as they get older. Some throw red, some white feathers. We should not breed from such a one.

BREEDING FOWLS PURE FROM A MIXED RUN (*R. H. F.*).—Separate your fowls, and as the majority are probably not yet laying, you will lose little time. The Cochins and Brahmas will both do well in confinement; let the Dorkings have the run. At the end of three weeks or a month of separation you may safely set the eggs.

SIGNS OF POISONING IN FOWLS (*H. T. R. L.*).—The liver will be very much inflamed, the blood-vessels of the brain and intestines full of blood, while the inner coatings of the bowels will show red patches, and be honeycombed in places, unless some of the bile poison with which we acquainted should be used. We are led to this last remark because your fowls seem to be killed instantaneously.

CAPONISING (*Beeborough*).—The art of making capons is but very little practised in England. It is cruel, because it entails much suffering; it is expensive, because nearly half of the fowls operated on die; it has been given up, because the art of feeding poultry in England is now so well understood, that when a fowl has attained the age at which the operation can be performed it is as large as it would be some months afterwards. The thigh of such a fowl is as tender as that of a chicken, while the leg of a real capon is tough and stringy. The operation can, no doubt, be performed on Ducks and Geese, but we have never seen it.

SWEDES AND MANGOLD AS POULTRY FOOD (*R. E. H.*).—The Swede greens are very good for fowls, and we suppose Mangolds would be the same. We have never tried the latter. We grow late turnips on purpose to give the greens to poultry. They always have the root. If we gave roots we should give them raw, and chopped fine. We tried steaming Swedes once, but it was a failure. They seemed to run to water.

BREEDING WHEATEN BANTAMS (*Bantam Breeder*).—You must breed from two sets of birds to get cocks and pullets, the chief point you have to bear in mind being to cross judiciously. If you, at an exhibition, are taken by a pen which by the great merits of the cock, coupled with good hens, proves too much for your better hens that are weighed down by the inferiority of the cock, you may safely infer you have the hens, but you have not the cock. You must get a good cock of the successful breed, and put him to some of your best hens; from these you will breed cocks, while you already possess the hens. If you have runs enough, get two hens of the successful strains, and put to one of your cocks. You will then probably have what is almost an impossibility to breed winning cocks and hens from the same parents. The breast and hackle of a wheaten hen should be of the colour of a grain of red wheat.

POINTS IN NUNS.—"In reply to 'JACK,' five, six, or seven black feathers in each flight would equally apply. Birds having more on one wing than on the other would not be excluded from winning a prize, if they were not overshot. The white feathers must form a perfect saddle. Jacobins must not have white thighs, but be black, red, or yellow from the under mandible down to the vent, according to their colour.—F. W., *Birmingham Columbarian Society*."

STAMPING PIGEONS (*A. H. W.*).—It is usual to stamp the wing. You must not put any stamp on birds which you exhibit, as you would lose a prize.

FLIGHT FEATHERS IN NUNS (*W. E. E.*).—We gave the number of six in each wing on old and high authority, but certainly though the number of six dark feathers is a good medium to hit upon, yet more would be better, taking in, in fact, all the larger flight feathers. Under six would be too few, but the great thing is to have an equal number on each side.

TEMPERATURE OF AVIARY (*D. K.*).—If for Canaries only it is immaterial. They will stand the frosts and snows of winter if kept in an open aviary all the year round, provided it be roofed-in and they have a chance of finding shelter behind snug corners of the rafters, like sparrows in an outho use.—W. A. BLAKSTON.

REMARKS.

24th.—Dreadful wind in the past night, and the barometer fell to 28.332 at 4.47 A.M. on this day, being the lowest since 1849. A fine morning, showery after 1 P.M., fine night.

25th.—Wet and stormy morning, showery all day, but fine about 10 P.M., rain in the night.

26th.—Fair but dark and damp, showery and often dark during the day, fine at night.

27th.—Fair though dark in morning, but soon improved, was fair all day, and at times very bright.

28th.—Still fair but misty and close in early morning, intense darkness from 11.55 A.M. to 0.10 P.M. finer in the afternoon.

29th.—Fair but dull, a little sunshine about 2 P.M., then dull and showery the remainder of the day.

30th.—Dull though dry, gleams of sunshine between 1 and 2 P.M., and fair after, fine at night.

The unusual depression of the barometer has brought no material change in the weather, which continues unusually warm, damp, and dull.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 31.

THE abundant supply of out-door produce of home growth, and the additions made to it from the Channel Islands, have a marked influence on our markets, and although the attendance is good in general, no advance can be obtained. English Apples of first quality are scarce and dear; American Newtown Pippins good, but not plentiful this season. Pears comprise Ne Plus Meuris, Beurré de Rance, Josephine de Malines, and Knight's Monarch. A fair amount of business is done in the Potato trade, though stocks are heavy.

From observations taken near London during forty-three years, the average day temperature of the week is 45.0°; and its night temperature 30.4°. The greatest heat was 65°, on the 10th, 1831; and the lowest cold zero, on the 13th, 1855. The greatest fall of rain was 0.52 inch.

CABBAGES.

HOW many distinct and typical forms of garden Cabbages have we in cultivation, or what are we to consider as such? Attention is being directed to this subject through the following announcement in the new schedule of prizes offered by the Royal Horticultural Society:—

Special Prizes offered by Messrs. Barr and Sugden, of Covent Garden, for the year 1872.—Assortment of the most distinct and typical forms of Cabbages, named (not including Savoys). Two examples of each, not less than 10 distinct kinds. £5.

The Prize to be competed for successively at any of the Meetings in the Autumn of 1872, as the various sorts may appear in condition.

Note.—The object of the prize is to ascertain what really distinct forms of Cabbages are in cultivation. The plants must be exhibited in their integrity as far as possible—*i.e.*, with the roots, leaves, &c., so as to show their true character.

N.B.—A similar prize will be offered by the Society for competition at any of the Meetings during May, June, and July, 1873.

This is prize-offering of a praiseworthy character, for which Messrs. Barr & Sugden deserve our special thanks; the object being, as stated, "to ascertain," and as we understand it, to fix and record in some tangible manner for general benefit and reference, the various permanent and distinctive typical characteristics of this important class of vegetables.

It would be of the very greatest importance indeed to the whole vegetable-growing community, could every distinct and typical form of vegetable be so figured or described that at any future time it could be easily recognised. We want a sort of descriptive vegetable album as an authority or standard to which we could at all times refer. Vegetables are all greatly inclined to variation—to deterioration, in fact. It is only by immense care and trouble on the part of our seed-growers, which the ordinary cultivator knows nothing of, that our vegetable stocks are kept so pure and true as they are. This tendency towards variation leads inevitably to the multiplication of names, and so in time to the actual loss of the identity of the original.

But to return. Messrs. Barr & Sugden wish to ascertain what really distinct forms of Cabbages are in cultivation. We venture to say, Very few—far fewer than the long lists of names in our seedsmen's catalogues would lead us to suppose. What, however, is or will be considered a form or type? and where is the authority? Intending exhibitors will be anxious to know all about this. On looking over some half-dozen of the trade seed-lists of this season we find no fewer than eighty-four sorts of Cabbages bearing distinct names, and which are all (presumably) sold as distinct. We can scarcely suppose that, although these are sold as distinct sorts, they will be accepted by the Fruit and Vegetable Committee as sufficiently distinct forms. No, a particular name, although a generally recognised one, does not confer distinctness. These points, however, must be left to the decision of the Judges, who, consequently, will have no light or easy task to perform.

Anyone at all conversant with Cabbages is well aware of how they sport and vary. Go into the market gardens, see in a ten-acre field if you cannot pick out nearly as many distinct Cabbages as you will find in a collection of thirty or more named sorts, not including the rubbish, from one of the London seed houses. The market gardener has only one stock of seed saved with the utmost care from his very best examples, and yet the plants exhibit all this wonderful variety—some early, some late, some small, some large. This liability to variation is greatly influenced by seasons; sow from the same bag of seed the following year, and not half the variation will be seen. This is how new Cabbages, at least new names for Cabbages, are manufactured. Seed is saved from these accidental variations, and named Jones's Early, Smith's Champion, or Robinson's Superfine, as the case may be, and for a season or so some of their peculiarities may be retained.

The reputed varieties of Cabbages are far too numerous, and the distinctions far too trifling; so that we hope this prize offered by Messrs. Barr & Sugden will be the means of putting us a little right in the matter. How very annoying it is, in endeavouring to keep up our supply of Cabbages throughout the season, to find, after having ordered ten or twelve sorts of "lates" and "earlies," that from one packet of the true London Market the same results could have been obtained.

In 1862 a trial of sixty-one named sorts of Cabbages was made in the Royal Horticultural Society's garden, Chiswick, and as the Report states, the Committee only found five distinct, no less than twenty-eight of them being synonymes or more or less impure stocks of the London Market, Fulham, or Battersea. In this, the year 1872, the Report has pretty much the same application; many of the same names, indeed, are still advertised. Embodying the synonymes given in this Report, therefore, so far as applicable to the present time, added to our own observation and experience, we subjoin a list of what we consider the most distinct and typical forms of garden Cabbages.

1. Early York.—Very distinct. Head small, oval; leaves dark green, showing very little rib. A very early sort, the best to sow early in spring for early summer use. If sown in autumn to stand the winter it is apt to run to seed.

2. Little Pixie.—Dwarf. Heads small, more pointed than those of Early York, and of a paler green, with more ribs.

3. Atkins's Matchless.—Dwarf. Heads pointed, larger than Little Pixie.

4. Sugarloaf.—Very distinct, dwarf. Heads small, the leaves heading over like a Lettuce, and of a peculiar pale green colour. This seldom hearts firmly, although appearing to do so.

5. Nonpareil.—Allied to, but perfectly distinct from, the London Market; the heads smaller, more rounded. McEwen's resembles this.

6. London Market.—The great London market Cabbage. Distinct. Leaves large, round, broad, with thick midribs, and forming large, solid, roundish, somewhat pointed hearts. Dwarf. The best variety to sow in July for early summer use. The following are a few of the synonymes:—Fulham, Battersea, Vanack, Enfield Market, Emperor, Mitchell's Prince Albert, Wellington, Sheppard's Marrow, Shilling's Queen, East Ham, King of the Cabbages, Cattell's Reliance, and Champion.

7. St. John's Day Early Dwarf Drumhead (*Chou Jeannet*).—Very dwarf. Heads large, flat, like the Drumhead or Cattle Cabbage. Very crisp and tender. A most excellent Cabbage for autumn use. Sow in April, and plant in rich ground 15 or 18 inches apart for September and late autumn use.

8. Winnigstadt.—Dwarf stem. Heads large, broad at the base, tapering or conical, very hard. Boils very tender. Leaves glaucous. Unprepossessing at first. Exceedingly good in dry summers. Sow in July or August for use the following July and August. It requires much the same treatment as Red Cabbage.

9. Pomeranian.—Stem tall. Heads exceedingly long, pointed, becoming very hard. Excellent. Somewhat in appearance like the Winnigstadt, but taller, more pointed, and having the leaves pale green, not glaucous.

10. Drumhead.—Tall. Heads very large, flat. Plant exceedingly robust. Coarse, scarcely admissible as a garden Cabbage.

11. Portugal Cabbage (*Coure Tronchuda*).—Very distinct. Leaves large, pale green, with very thick fleshy white midribs, which cook like Sea-kale. Hearts sometimes close and firm. Flowers white. Sow in spring for autumn use.

12. Vaugirard.—An interesting variety, coming into use in winter. Rather coarse. Heads of medium size, flattened. Leaves slightly tinged with brown.

In addition to these we have the Coleworts, the Savoy Cabbages, and the Red Cabbages. The above, therefore, represent the most distinct types of garden Cabbages. Of No. 1, Early York, there are several forms, but all easily recognised; also No. 4, Sugarloaf, is quite distinct. Nos. 2, 3, 5, and 6 all more or less resemble one another, and form the main body of what we term White Cabbages.

We could extend the list of names and our remarks further, were it necessary, and give selections of varieties from the seed catalogues before us, stating the type to which each belongs, but we think we have said enough to show that there are not many distinct forms of Cabbages, that two-thirds of the names found in commerce are applied to mere variations, more or less pure, of the great London Market Cabbage of Covent Garden.—B.

AURICULA GOSSIP.

Now that the time for promoting the spring growth of this lovely flower has arrived, and all growers of it will soon be busy top-dressing—an operation I never leave to other hands than my own—it may not be unseasonable to say a few words about the Auricula and its prospects. And I do this the rather as I have received during the past week letters from my old correspondent Mr. George Lightbody and from a brother clergyman, unknown to me personally, but the son of one who in former days stood high in the rank of florists, and whose collection of Tulips and Auriculas was known throughout England.

There is, I think, from what I see and hear from others, a prospect of a good bloom this spring. The very mild winter that we have had has been a favourable one for the flower, where care has been taken to keep out wet and to give air on all possible occasions. I have never had my own collection in better health or showing more promise of a good bloom, and I hear the same report from others. May we not hope, then, that at the April Show at Kensington we shall find a beautiful array to delight all lovers of the flower, and, it may be, astonish outsiders? One thing we may rest assured of—that from the collection of Mr. Turner, of Slough, there will be a magnificent display staged. The Slough Auriculas have been long famous, and now they have attained an extent in amount and quality which we may fairly say is unequalled. During the autumn he became the possessor of a large collection belonging to a grower near Glasgow, containing between five and six hundred plants of all the best known varieties; while he had previously purchased the collection of that veteran grower, Mr. Headley, of Stapleford, the raiser of George Lightbody, Conductor, &c., and in this are, I have reason to believe, some remarkably fine seedlings, especially amongst green edges, so that here will be a treat in itself for the lovers of the Auricula.

The mention of seedlings reminds me that some of our oldest raisers are retiring from the field. Campbell, of Falkirk, the raiser of Pizarro, Lord Palmerston, Robert Burns, &c., who is now seventy-three, will sow no more seed. He has been working indefatigably for the last twenty years to obtain crimson selfs with a good paste from old Lord Lee, and now believes that he has succeeded. Then Mr. Lightbody also gives up; he is well known as the raiser of Richard Headley, Fair Flora, Lord Clyde, &c. Mr. Robert Traill, another veteran grower, the raiser of Mayflower, General Neill, &c., also retires from the field; and last, but not least, Mr. Headley. It shows the difficulty of raising seedlings of any moment, that these growers, who have been for thirty or forty years engaged in thus raising seedlings, have only left some half-dozen varieties of any note in the catalogues, and even of these some will be perhaps displaced by-and-by. It is an honour, then, to be the raiser of a good Auricula, and testifies to patient endurance and perseverance; and let us hope that both north and south of the Tweed the mantle of these patient workers may fall on some who will be ready to take up the work.

There is one disadvantage connected with it—years must elapse before a seedling that passes muster can be distributed to the public, and then only in small quantities. You cannot propagate an Auricula as you can a Pansy or a Verbena; it will "gang its ain gait," and some sorts are very shy indeed in producing offsets. Hence it is that a flower like Colonel Taylor, which is forty or fifty years out, will still fetch half a guinea. On the other hand, there is the advantage that one is not for ever recasting one's stock, while the necessity for adding new varieties is much less than in any other florist's flower with which I am acquainted. How few of the Dahlias, Hollyhocks, or Pansies, of twenty years ago even, are cultivated now!

At my last repotting in August (for after all I believe that to be the best time for the operation; I have tried May, but it did not seem to succeed so well)—I used much less rich compost than I have hitherto done, and, as far as I can see as yet, with manifestly good results. Amongst my small stock I see a good deal of health, and my winter losses have been comparatively nothing, while I find the pots well filled with roots; and now, with a good top-dressing of sheep's manure well rotted, I hope to have a vigorous bloom. There is one thing I am especially anxious to avoid, and that is coarseness; for one of the greatest charms of the Auricula is its refinement; and when by overfeeding and stimulants this is lost, I think the result is fatal to this special beauty of the flower. I think at some of our metropolitan shows a mistake has been made in allowing plants to be shown with two trusses. In old days the symmetry of the plant as well as the beauty of the flower used to be considered, and when plants were shown in pairs an equality in the style of growth was insisted upon also. It may sound very well to have Auriculas like Cabbages with large overlapping leaves, but I think that the neat, stiff, symmetrical foliage is far more to be sought after. It is the same as with the Hyacinth. Surely the stiff erect foliage is more to be desired than the limp leaves which require to be tied up to prevent them falling over the sides of the pot. I think, too, the plan of showing an overcrowded truss is bad. I have seen them with as many as fifteen pips. Now, I believe one with a truss of seven, or at most nine pips, is a prettier object. All these, which I believe to be defects in showing, come from the idea, too prevalent now-a-days, that size is the test of excellence of growth.

It would only be reiterating an oft-told tale were I to mention which I consider to be the best varieties, and novelties are so few that they give one but little trouble. We shall probably see some this season from the Stapleford stock; while of Alpines, however pretty they may be and are, I must, as a bigoted old florist, say they will bear no comparison with the florists' varieties. They are indeed to be had in abundance. Mr. Turner has made a wonderful advance in them, but after all they must hold a subordinate place in the love of the Auricula-grower.—D., *Deal*.

MRS. PINCE'S MUSCAT GRAPE.

After the excellent article of Mr. Foote, page 106, I shall be very glad if Mr. Meredith would give us his experience of this Grape, he having had it in cultivation for some years; in fact, I know he has a house devoted entirely to this variety.

I myself have not succeeded in colouring this Grape as I should like, though I have grown it fine in bunch, and the flavour was all that could be desired; but I believe it must have a house to itself to ripen well, and another thing I believe is, that it will bear finer bunches on the rod or extension system than the spur system. I shall hope to see others contributing their experience of this fine variety of late-keeping Grape.—Stephen Castle.

ODONTOGLOSSUM ALEXANDRÆ AND LYCASTE SKINNERI.

The first meeting for the season of the Royal Horticultural Society (January 17th) was a most interesting one. The beautiful banks of Chinese Primulas and that increasingly useful flower the Cyclamen, Lord Londesborough's Orchids, and those sent by Messrs. Veitch and others, were worthy of all praise. But it is of the two species whose names are at the head of this paper that I want to write. The superb plant sent from Lord Londesborough's collection, and named by the Committee Odontoglossum Demisoniæ, is worthy of special notice. It is presumably a form of O. luteo-purpureum; the flowers are 3 inches in diameter; the sepals and petals are much elongated and pointed, as in O. luteo-purpureum. The colour is white tinged with rose and very slightly spotted, as in O. Alexandræ. In O. Alexandræ var. Bowmani, sent by Messrs. Veitch, we have the flowers large, well-shaped, and more densely spotted than in the type. Each recurring importation of these beautiful Odontoglots brings out new forms and serves to keep alive our interest in them.

Both of the species referred to are natives of New Grenada, and are found growing at an altitude of from 7000 to 8000 feet. Their culture is comparatively easy, and no garden where there is sufficient means should be without them. Their culture is as yet imperfectly understood by gardeners. I visited many gardens in the north last autumn, and found plants of O. Alexandræ had been added to small collections, and were being treated to the heat of a warm stove as well as free exposure to the sun. Such treatment can only end in failure: the pseudo-bulbs will shrivel, and the young growths be checked.

If a house has to be erected for this class of plants let it be a lean-to with a north exposure. At The Poplars, Leyton, the residence of F. G. Wilkins, Esq., there is a very excellent collection in a house of this description under the care of Mr. J. Ward. The pseudo-bulbs are plump, and the vigorous young growths throw up strong flower-spikes. The temperature in this house during winter falls as low as 35°. In the north of England and in Scotland, where the sun's rays are less powerful, the form and situation of the house may be different. At Meadowbank, near Glasgow, I found they were grown in a span-roofed structure running east and west, the plants close to the glass; indeed, this is important whatever the form of house. I grow them in a small span-roofed house with a night temperature of 45° in winter, but it is necessary to remove them to a cold frame in summer, as the excessive heat shrivels the pseudo-bulbs. The frame is placed under a north wall. The plants should not be overpotted; tough fibrous peat and fresh sphagnum chopped fine suit them, a few potsherds being added to keep the compost more open. The pots should be half filled with drainage.

Lycaste Skinneri.—The splendid assortment of ten distinct varieties exhibited by the Messrs. Veitch, of Chelsea, was a very attractive feature in the meeting. They had L. alba, the pure white variety; L. albida, white, with just the faintest tinge of rosy blush fringing the margin of the sepals and petals. Equally beautiful were the varieties more after the normal type, some with the lips white, others with beautifully blotched and spotted lips; one had a deep crimson lip. This is another class of Orchids, easy of culture, and to be obtained at a low price. One of the staff officers of this Journal said to me, "I do not grow Orchids. I will go in for Lycaste Skinneri by the dozen." The flowers are numerously produced, and last two months in beauty. All the varieties are from Guatemala, and were first introduced by the late Mr. Skinner.

Lycaste Skinneri is one of the very best winter flowers we have, and it succeeds in the cool Orchid house, although I have grown it very well in an ordinary plant stove, the plants being removed to a vinery at rest when the growths are matured. It does not succeed in a very low temperature. As an experiment I placed a plant in a cool greenhouse for the winter, and nearly lost it. The plants delight in a comparatively moist atmosphere and a temperature of 50° during the winter. When they are in flower they may be placed in a warm greenhouse or sitting-room without any fear of injury. The cultural remarks are easily summed-up. The compost is the same as that recommended for Odontoglots, and, like them, they require plenty of water when growing; and even when at rest they must not be allowed to become quite dry.

All the species of Lycaste are easily propagated by division when the plants are at rest.—J. Douglas.

KEEPING LATE GRAPES.

My experience in keeping Grapes this season is totally different from that of your correspondent Mr. W. Moore in page 86, although he has a structure for the purpose. I have now some fifty bunches of Lady Downe's and Black Alicante. They were cut from a span-roofed vinery with an inside border at the end of October. The house was then filled with Chrysanthemums, and it is so at the present time; it has also been regularly watered. The temperature at noon to-day (January 31st), was 48° without fire heat. In the same house are three young Vines, first year of fruiting—namely, one Black Muscat, one Muscat Hamburgh, and Mrs. Pince grafted on the Black Hamburgh. The fruit on these is rather shrivelled, but not decayed. The bunches cut in October are in a dark closet in my house, no ventilator except at the door, in bottles as Mr. Moore has them, with a little charcoal in each bottle. The temperature is 45° at noon and not a berry is cracked, and there are very few signs of cracking. They appear as if they would keep some months.—D. H.

My Grapes were cut on October 6th, and were chiefly Black Barbarossa (Gros Guillaume), and the stems were placed in quart bottles filled with spring water, and hung up in an airy garret close to the wall. I cannot claim great success for my experiment, but few of the berries burst. They kept plump for some weeks and afterwards began to shrivel, but in that state they became very tolerable raisins, and were found acceptable by my family. I have one bunch still left.

I intend to try the experiment again, and hope to be more successful, as I attribute the shrivelling of the berries very much to the fact of the Barbarossa not being so well finished as I have had it in former years, last autumn being unfavourable to bringing this Grape to perfection, as you are aware it requires a high temperature to ripen it. My object in writing is to recommend the Barbarossa to Mr. Moore and others as a better keeping Grape than the Alicante.—John Ferme.

My impression has always been that Grapes have the power of taking up water through the stem in the absence of leaves, hence my weighing the bunches as stated in the paper sent to you in order to test this. These bunches proved that such is the fact, although many gardeners of standing with whom I had communicated on the subject prior to my adopting the water system repudiated the idea, and argued the impossibility of the berries of Grapes having such power.

I am strongly impressed that at this time the true principle of keeping Grapes in water is not understood, and until it is so no correct practice can be founded. I am far from saying that none of my friends have succeeded in keeping them; but what I say is, the principle of their success is not thoroughly known, and therefore cannot be relied on practically. The information I should like to see conveyed through the pages of the Journal is, What is the lowest temperature at which Grapes can take up water in a perfectly dry room? Can Grapes evaporate the water so taken up through their skins, and, if so, at what temperature? Is not light a desirable agent? Is it of consequence to have the leaf ripe at the time of cutting, and if so why? always supposing the fruit to be thoroughly ripe. This and other important information I should like to see detailed.—W. Moore, *Belton Gardens*.

TOMATOES IN POTS.

I cannot agree with Mr. Douglas's remark at page 50, that Hepper's Goliath Tomato, in pots, carries a crop of very small fruit with one of immense size. I grew it last year in pots, and on every plant, ten in number, I left five or six fruit. These swelled to a great size, some weighing upwards of 1 lb., others less. They were the finest Tomatoes I ever had, and were considered by all who saw them to be by far the largest

that had ever come under their notice. I also planted out eight plants against the south wall, side by side with the old Red, a good variety, and I found Goliath bore quite as numerous a crop, and some of the fruit swelled to a much greater size.

I quite agree with Mr. Douglas in stating that gardeners exhibiting collections of vegetables in June will find a good dish of Tomatoes a strong point in their favour. If size is any object, I have no hesitation in recommending Hepper's Goliath.—James Smyth, *Fynone, South Wales.*

USEFUL FOREST TREES OF INDIA.

The Teak is of peculiar value for shipbuilding and other purposes from the power of the oil to conserve iron. Teak is by far the most valuable of Indian woods. The first-class Teak for shipbuilding takes seventy or eighty years in coming to maturity; for house-building and furniture there is a ready sale for the thinnings in twenty years.

Sál wood is used for engineering purposes, for shipbuilding, and for house-building. The trees grow very close together. Planting is not required; the seeds fall viviparous into the ground. This wood takes a long time to season, and it is liable to the attacks of some insects. The best of the Deodar timber comes from territory which is not British.

Deodar is, in fact, used for sleepers, but it is far too valuable a wood for that purpose. Then there is black wood, of great value for ordnance purposes, for house-building, and for carved furniture; it is planted in the same situation as Teak, and can be obtained of as large size as Teak.

Ebony is a wood of great value, and sold by weight. The Chinchona cultivation has been a remarkable success on the Neilgherry hills. It is of extremely rapid growth, and the bark of commerce is obtained at an early age. There are at least 2000 acres of Chinchona on the Neilgherries. It is expected that the leaves may yield a febrifuge for the masses.

Of Bamboo there are several species; next to the Cocoa-nut, the Bamboo is, perhaps, the most valuable wood in India for domestic purposes.

Rattans grow in great abundance in the forests of Malabar. The Rattan is a species of Palm, the stem of which runs along the ground for great lengths (80 feet to 100 feet or more); it is a product of considerable value, and likely to become a larger article of trade.

Caoutchouc and gums of similar properties are found largely in Assam. Recently rules have been laid down for the periodical tapping of the trees, in order not to overtax them.

The Breadfruit tree is grown in gardens. The Betel-nut is a valuable tree. The Casuarina, or Beef-wood, is a very useful tree, of rapid growth, and the timber of great hardness. It is quite large enough for building purposes. The wood is very hard, and turns the edge of the axe. It has the peculiar property of durability under water.

The Satinwood is much used for picture frames and fancy purposes; it resembles the American Maple. The Indian Dog-wood, a small tree of about 15 feet, is considered remarkably suitable for charcoal for gunpowder purposes.

Many other species of wood might be mentioned which it will be useful to conserve and propagate—the Red Cedar and other species of the Mahogany family; Ironwood, which is practically imperishable, and so forth. The cultivation of wood for fuel is of importance; in the drier parts of India it is so deficient that manure is burnt, and consequently the land is starved and production diminished.—(*Times*)

GRAFTING.—No. 2.

In our last we gave examples of inarching from Mr. Baltet's book, and we now continue the subject. There are some plants which cannot be grafted with certainty in the ordinary way by a free scion, and, therefore, recourse must be had to inarching. Mr. Baltet in his work gives various examples of this process, but as they all illustrate the same thing we shall content ourselves with giving the following extract:—

In commercial establishments there are sometimes new kinds of trees cultivated in pots. If it is desired to propagate them as standards, large stocks are planted, and the stock plant is raised to their height on a slight stage (*fig.* 1). To sustain the stock plant during a period of prolonged drought it will be convenient to place the pot in one of greater size, and to furnish the interspace with moss or fine sand to preserve the freshness.

An opposite example to the preceding is frequently met with in gardens. The stock plant is very strong and branched.

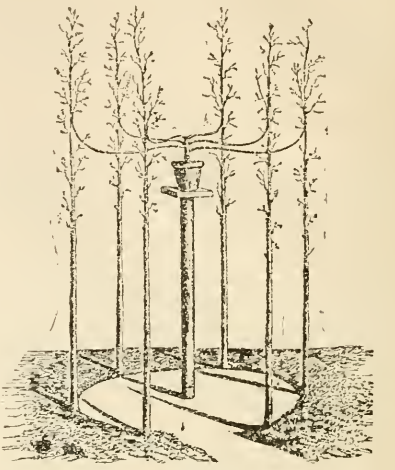

Fig. 1.

The extent of its roots and the shade of its foliage do not permit of young stocks being planted around it. To propagate it, young stocks must be cultivated in pots. In the second year after potting they are brought in contact with the branches of the tree to be grafted by means of a graduated stage. The pots being placed on this stage they are plunged in a bed of moss, tan, sand, or other light matter to preserve their freshness, for watering there will be difficult, and the rain and natural dews will be intercepted by the foliage.

Inarching for the Restoration of Plants.—Inarching is not the only mode that can be employed for the restoration of defective plants; but it is valuable where it serves to change the variety of a tree, to renovate the stem, and to repair the branches. Let us give a few examples.

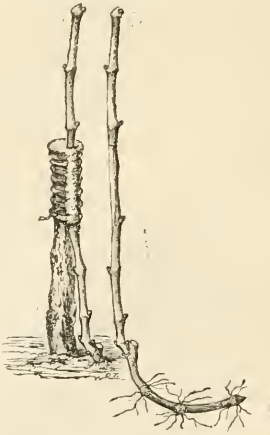

Fig. 2.

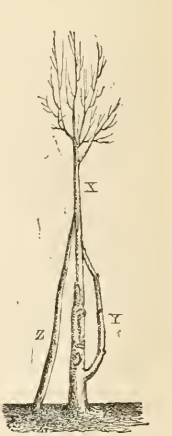

Fig. 3.

1st, *To Change the Variety.*—The Vine is subjected to this process by planting alongside the stock in winter a young-rooted

plant of the variety to be inarched (*fig.* 2). The time of inarching, which will be in April, having arrived, cut the stock to the height of the new plant, and as low as possible. Cut a longitudinal notch in the upper part of the stock, and a corresponding cut in the scion of the stock plant, leaving two or three eyes above it. When the graft is bound and waxed, the shoots of the stock plant are removed and kept in subjection.

2nd, *To Restore the Stem.*—The stock (*fig.* 3), the stem of which is cankered and furnished with gross shoots at the base, may be repaired by means of these shoots (x), which are buttress-grafted on the same stem above the wound. The course of the sap interrupted by the decay will then be re-established. In default of branches being found on the diseased tree, a strong stock (z), is planted in close proximity to it. After a year of good growth, head-down the stock z, and introduce it above the canker of the stem by means of buttress-inarching [as described in our last week's number.] When one stock is not sufficient for the regeneration of the tree, several may be planted round the old one and inarched in the same way. Consequent on this operation the diseased stem can be removed.—Baltet, *L'Art de Greffer.*

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 26.

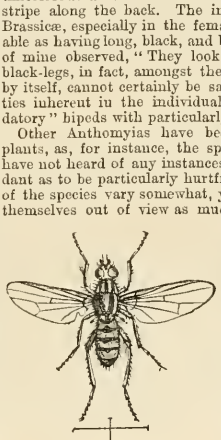
Being rather at a loss for a commencement, I think I cannot do better than offer a remark, by way of opening, upon some observations made by a contributor to this Journal, who has, what I do not profess to have, that practical knowledge of the habits of bees derived from bee-keeping. He complains that I have calumniated his favourites by very unkindly classing them amongst predatory garden insects, though I guarded my statements by admitting that they were only occasionally injurious. Their obvious partiality to sweets would certainly lead one to suppose that they would not hesitate at all to help themselves to any fruit which afforded saccharine matter, provided the supply from flowers ran short. I have not at hand the volumes of "Science Gossip," but in its pages a few years since there appeared communications, evidently written *bonâ fide*, wherein it was asserted that in various parts of England and Scotland, during a scarcity of wasps, the bees attacked the fruit; and my friendly critic must remember that, even if his statement is correct that bees will not meddle with fruit which is not beginning to decompose, they would still merit the name of predatory insects, for a good deal of fruit which has been injured by the weather and other causes is still available for some purposes. As to the perforations produced by bees in the corollas of some flowers, these are certainly disfigurements rather than actual injuries. Not very many cases have been recorded, but I have no doubt at all it is a thing which bees often do. It is only noticeable by the observant amongst our gardeners, the number of whom, though gradually increasing, is not so large as one could wish. So much for the tenants of the hive, which we will now dismiss. I have only to add that I am astonished to hear that the sting of a bee may be, if not agreeable, at least beneficial; so that, reversing the proverb, what is "poison" to some is "meat" or "health" to others. Possibly; still I doubt.

Many species belonging to the Dipterous order of insects are exceedingly fond of sporting in the sunshine, sometimes singly, sometimes in groups. So is it with those flies especially belonging to the genus Anthomyia, the tints of which are considerably varied, though made up o few colours, chiefly black, grey, and a reddish brown. The cause of this is that the wings and even the bodies of these insects show shifting hues, according to the direction in which the rays of light fall upon them. Frequently parties will cluster about the heads of composite and umbelliferous plants, at other times they rise high in the air, and the horticulturist, who knows how injurious some of the insects are in their preparatory stage of larva life, is tempted to wish they were not quite so lively. There are several species of these Anthomyias which frequent Cabbages and Cauliflowers. Anthomyia Brassicæ also attacks Turnips, but is not so frequently hurtful to them as to the plants from which it takes its name.

The unpleasant-looking larvæ or maggots of A. Brassicæ have been detected at almost all seasons, but in the colder weather of winter they become sluggish for a time. During May and June the species may be detected in all its stages. The pupæ are not to be found in the roots, when they are mature the maggots withdraw from their food and enter the earth. The maggots, it may be observed, though less in size, have some resemblance to those of the ordinary meat fly (M. vomitoria). The colour is yellowish white, there are no legs, but the head is furnished with two black hooks. The tail is blunt, and has two brown spiracles and some minute spines. The effects of the jaws of these little creatures is soon manifest, even by the external appearance of the roots; they become enlarged, and of an unhealthy colour. On pressure, or cutting them open, the interior is discovered to be full of cavities, within which the larvæ feed; and, in fact, the mischief is rarely discovered until the evil has gone too far for there to be any chance of saving the particular plants. Active as the flies are also at the time they take their excursions in the air, the females act very differently when engaged in their maternal employment, and go very stealthily to the work of oviposition. However, if we cannot find the eggs we can boil them or the newly-hatched maggots, and no doubt hot water poured close to the stem would be as efficacious here as it is in checking the ravages of the occasionally troublesome grub of Tipula oleracea, alias gaffer or daddy-longlegs.

To Cauliflowers the above species of Anthomyia is very hurtful in some seasons. The eggs have been detected attached to the stalk just below the ground; and burrowing in the fashion already described, the maggots soon bring the plant into a miserable condition. The very closely-allied species, A. radicum, makes Turnips and Radishes its speciality, its habits being similar, but its times of appearance different. The flies in this case appear in April, and the evil effects of the jaws of the larvæ are most noticeable in the autumn, whereas A. Brassicæ shows itself to be more hurtful in the spring or early summer. The larvæ of radicum are not so unicolorous as those of the other species, having a greenish stripe along the back. The imago, or perfect fly, resembles Brassicæ, especially in the female. Both species are remarkable as having long, black, and bristly legs; in fact, as a friend of mine observed, "They look like pests, and so they are," black-legs, in fact, amongst the flies; but length of leg, taken by itself, cannot certainly be said to be a proof of evil qualities inherent in the individual, for I have seen some "predatory" bipeds with particularly short legs!

Other Anthomyias have been noticed to affect Cabbage plants, as, for instance, the species called trimaculata, but I have not heard of any instances where this has been so abundant as to be particularly hurtful. The habits of the maggots of the species vary somewhat, yet they are all careful to keep themselves out of view as much as possible. Curtis, as far back as 1841, had called attention to the proceedings of A. Lactucæ, which had for some years previous destroyed much of the Lettuce seed in the eastern counties. The maggots of this species live in the flower-heads, and devour the receptacle and immature seeds.



Anthomyia Lactucæ.

The name of Coccus is almost, though not quite, as unpleasing in the ears of the gardener as that of Aphis and though mankind is greatly indebted to another species of the first genus for one of the most brilliant of colours, still this is scarcely an equivalent for the injuries done by Cocci to the Olive, the Vine, and various fruit trees. The Cabbage tribe have a tormentor of this sort, an account of which first appeared in the old series of the Transactions of the Entomological Society. Kirby, in speaking of it, remarks that "In 1836 much injury was done in the market gardens to the west of London to the Cauliflowers and other plants of the Cabbage tribe by a species of Aphis covered with a purple powder, which had not been before observed by the gardeners." This might suggest to some the idea that it had been introduced from a foreign country, like the so-called American blight. It is more probable, however, that it had previously been overlooked. By writers who subsequently studied its habits it received the name of Aleyrodes proletella, or, still more unsuitable, the Cabbage powder-winged moth, it having no claim at all to the latter name, as it plainly belongs to the Hemipterous order, and is, properly speaking, a Coccus. The females of this species settle down in a very insidious way upon the Cabbage leaves during June and July. "When about to lay their eggs,"

says one, "they remain quite quiet on a leaf for several days, and after they have left the spot on which they have rested, a small space covered with whitish powder is observable, round which are irregularly deposited from ten to fifteen eggs." It is, however, the custom of the female in many other species of Coccus to die upon her eggs, and form with her dried carcase a sort of protective shield for the young progeny. In this case the shelter is less needed by the larvæ, which almost immediately after they are hatched spread themselves about the leaf. Sometimes the parent Coccus is to be detected near her brood, but her presence does not seem necessary for their welfare. The young larvæ are almost colourless, and very sluggish in their movements, performing their work of destruction by means of a rostrum or beak, through which they suck up the juices of the plants. They have six legs, and as they increase in size are not easily to be distinguished from the same insect in its pupal state. The females also have a scaly appearance. The males, which have the thorax and abdomen variegated with yellow and black, have four wings, which are distinctly seen, the upper pair being the larger; all are covered with a mealy substance, and in repose bent over in a sort of roof. It has been calculated that one female can produce 200,000 descendants, this being on the supposition that a month suffices for these Cocci to pass through all their changes; but though they can withstand the cold of winter, and may be found then in a condition of tolerable activity, their multiplication is retarded at that time. I have not as yet had an opportunity of counting the number of eggs deposited by the females, but I am inclined to suppose that it is much larger than the estimate quoted. The radical remedy for this enemy of the kitchen garden is the immediate burning of all infected leaves. Syringing and smoking the plants have their advocates, and no doubt some of the modern compounds sold for the destruction of Aphides are not at all agreeable to the Cocci. Amongst other insect enemies which keep them in check, they are persecuted by a Cynips, and also they are preyed upon by a small Acarus.—J. R. S. C.

HYACINTH CULTURE.

I THINK the following may be of service to amateurs like myself. I purchased a good many bulbs at Messrs. Stevens's, and I had some of them planted in pots and plunged in a frame in the usual way. When they had made plenty of roots they were taken into the hothouse, but as I had more than I wanted I put the others, without pots, in the hothouse in the cocoa-nut fibre in which I always keep my Ferns plunged in pots during the winter, taking care to cover each bulb with the fibre. After about three weeks they all shot through and showed strong flower-buds. I have now taken them up and planted them in fibre in china bowls for the drawing-room, six or seven in each, and they expand their blossoms beautifully, not suffering in the least from the removal. To show how they will stand pulling-about, I two days since took out of the bowl one plant in full flower, placed it in a separate pot, and it has not even flagged. I attribute this to the lightness of the fibre, which prevents the rootlets being broken in moving. I should add that the bulbs grown in this way are at least three weeks earlier in flowering than those planted and plunged in the usual way.—M. F. W.

ESTIMATE OF STRAWBERRY MERITS.

YOUR correspondent "T. G." (see page 9), desires the experiences of intelligent Strawberry cultivators; it would be presumption of me to class myself as such, but as I have paid considerable attention to, and taken the advice so often given in the Journal, I will communicate what I know on the subject.

It would save much dispute and disappointment if nurserymen were more careful in sending out varieties true to name. Some years ago I had occasion to add six new varieties, and of these only one was correct; and only two years since, wishing to try Garibaldi, I obtained a few plants from a nurseryman near me, but they all proved to be Vicomtesse Héricart de Thury. After a while he assured me that both varieties were synonymous, and yet this nurseryman sells both varieties! Such conduct I consider reprehensible, I regret to say that from being thus misled I stated in the Journal that Vicomtesse Héricart de Thury and Garibaldi were the same. To satisfy myself I obtained plants from a source from which the varieties ought to be supplied true, and I can affirm that Garibaldi is a distinct variety, but I must wait until July before I can report on its good qualities. Nor is it with one person alone that these mistakes are common, because I have what ought to be one kind from eight different sources, and no two of these Strawberries are alike or true to name; in fact, I can only depend on getting them true by applying to the raiser, to market gardeners, or to amateurs.

I find that success in the cultivation of the Strawberry greatly depends on the manner in which the plants are treated when young. Strawberries ought to be planted immediately when lifted, and at such a time and in such a manner that in twenty-four hours afterwards none could discover they had been transplanted. No after-treatment will make up for the careless way in which Strawberries are too often managed at lifting time and subsequently, as exemplified in leaving the plants exposed so that the rootlets are dried-up, packing many together and covering lightly with soil, and often covering the crowns as much as if they were intended for a salad. Such practices are sure to result in disappointment. Owing to some of these causes I have never been able to prove a Strawberry obtained from a distance before the third year, but plants under my own management I can to a certainty prove in a year from planting. Some varieties, no doubt, are hardier than others, but that there can be such a difference in some kinds owing to soil, I hardly believe. I have frequently noticed a great defect in a plantation, while the same kind on the same soil but differently treated at planting was luxuriant. I recommend liberal manuring, keeping the soil firm, removing runners often, and taking particular care not to allow any young plant to establish itself near the old plant. The presence of such plants, and of the centipedes so destructive to some varieties of Strawberries, particularly in dry seasons, are perhaps more general causes of failure than the soil. Also encourage the production of fresh rootlets by adding well decayed manure in a very narrow trench between the rows, as recently advised in these columns. Those who pursue a course like this will find that many varieties will succeed well where they previously failed.

I cultivate upwards of sixty varieties, and except where one variety surpasses another in productiveness they seem to grow much alike. The soil is light.—A LANARKSHIRE BEE-KEEPER.

GOOD VARIETIES OF PEAS.

I SEND you a list of varieties which I have found succeed well here. They are exposed to all winds from the west and north-west, the situation is high, and the subsoil is clay. Ringleader comes in first, Laxton's Prolific following about ten days later if sown at the same time. This is a first-rate Pea, and it is extraordinarily productive; neither wind nor wet injured it last year, and we had plenty of both. I think this variety ought to be more generally grown, it is far better than Supreme. Yorkshire Hero is very good. Prince of Wales was the best liked at table both in summer and autumn; for flavour I question if it can be surpassed. Veitch's Perfection holds its own. I cannot do without sticks as I find I can obtain a great many more pods with sticks than without them. Here tall-growing sorts are unmanageable owing to the exposed situation.—H. K., *Shadwell*.

ICE-STORING.—No. 1.

ICE being now as much a necessity as a luxury, it is not remarkable that extravagant means are frequently adopted to secure a supply of it for the many domestic purposes both of summer and autumn. By digging a pit in the ground, not coolness is sought but freedom from the variable influence of the atmosphere, and uniformity of temperature around the ice. This plan, however, is not, I think, the best that can be devised, and I shall accordingly proceed to describe the one which might advantageously be substituted for it.

The essentials of keeping ice seem to me to be—1st, A perfectly dry site; 2nd, Dryness and non-conducting power in the surrounding substance; 3rd, Exclusion of air. The first will be secured by the perfect drainage of the ground forming the site, which should command a good fall and outlet for drains, as the top of a hill rather than a hollow.

Now, I propose to make the ice house a decent building; there is no need, therefore, to bury it in an out-of-the-way place, but a naturally dry site may be chosen in a commanding position, where it will either be visible at a distance, or afford a prospect, or combine both. It may be fully exposed to the sun instead of being in a shaded spot, sunk to the depth of 6 feet

or less, but, if the drainage cannot be made very efficient, not sunk at all, made in the form a parallelogram with the ends running north and south, and the entrance at the north end. If an excavation be made it should be 36 feet long, 22 feet wide, 7 feet deep at the south end, and 5 feet at the north, the sides being 1 foot lower than the centre, so that the excavation falls 2 feet from north to south, and 1 foot from centre to sides. If no excavation be made, then merely take out the soil to make a firm bottom, giving the inclines above named—*i.e.*, from the north to the south end 2 feet, and from the centre to the sides 1 foot.

Fig. 1 is the ground plan of such a structure; *a* is the ice house within which the ground has been excavated to a firm bottom. The drain *b* is brought to a small cesspool within the ice house, which must be covered with a stone into which is let a 9-inch ordinary stench-trap. The stone should have a dish from the sides to the trap of 4 inches, and channels cut for drains to deliver water on the trap, so that the water from the melting ice may always pass it before going to the drain *b*. *c*, The trap, will require a stone 2 feet square and 8 or 9 inches thick, and should have a dish of 4 inches, and channels made for drains that are to convey the water of the melting ice. The stone to cover the cesspool need not be more than 1 foot square and deep in side measurement, and should be surrounded by bricks laid in cement. It should be laid on the cesspool in a bed of cement, and when set should rise 3 inches above the level of the excavation. The trap being in the centre of the house or midway at one end, it follows that it would, were we not to lower the excavation, be 1 foot higher than the side drains *d*, *d*; let the excavation, therefore, be made 15 inches deeper at that point, and slope to that depth, beginning 6 feet from the trap in the interior and falling to the trap evenly. In this case the side drains will have 3 inches fall from the sides to the trap.

Let the floor be formed of bricks, beginning with a brick-on-edge all round, and next to this 3-inch drain tiles, which should be laid about 1 inch in the ground, or so that they are level with the bricks on the other side laid on the flat. The whole of the space within the drains should be laid with bricks on the flat, and when this is done a floor should be made sloping from the centre to the sides, and from the interior to the trap, having the bricks level with the drain tiles and trap. Into this will fall all water originating within the house, and thence into the main drain *b*. The side drain will come to the trap by the channels made in the stone. The floor should now be run with cement, removing the drain tiles and putting a board to keep the bricks in the proper position until the process is complete and the cement set, then the tiles should be relaid, and those on the trap should be run in cement and cut so as to suit the stone. When this is done no water can escape but to the sides, and thence away by the drains, but as bricks are porous it is well to brush the floor thrice over with cement brought to the consistency of paint. After this is thoroughly set place bricks on the flat, each brick isolated, with 3 inches between each course, and the same between the ends, which will leave spaces of 3 inches between each course, both lengthwise and crosswise. The light spaces are the isolated bricks on the flat, and the shaded parts the spaces. These bricks should be laid in cement, and be bevel-pointed round to keep them firm. These bricks will keep the ice off the floor, and will allow the water to run off.

e, *e*, *e* Are 9-inch walls, which should have foundations below the floor of the ice house, and a course below asphalted, and one above the asphalted course laid in cement. Along the spaces *f*, *f*, a drain should be laid, and join the drain *b* where that crosses the spaces. Outside the spaces is *h*, another drain, that is intended to keep away all water from the enclosed space, and is the only drain, except *b*, that is to be below the excavations. It should have a syphon just clear of the house to keep back any air that may find its way up *b*, and keep it from the drains in the spaces *f*, *f*, which should have syphons at their junction with *b*. *i*, *i* Is an area which will require a wall, *j*, *j*, all round to keep up the soil—4½ inches thick if an excavation be made not more than 2 feet, and 9 inches thick if one deeper than 2 feet. *k*, *k*, *k*, *k* Are 6-inch iron pipes that have one end opening in the space *f* at the bottom, and the other brought to the external air, and should there be provided with a screw valve that is driven on an indiarubber washer, and so as to exclude air or admit it at will. *l*, *l*, *l* Are tongued and grooved doors made of sound well-seasoned oak or elm. They should have oaken frames, with an indiarubber band all round, so that there will be little possibility of air passing. The fastenings of the doors ought to be brass, as iron corrodes and gets out of order. *m* Is a porch having a stone floor or other hard material that will do for breaking ice on when filling, and as a storage of any straw or straw shutters that may be required for stopping up the spaces between the doors *l*, *l*, *l*; *m* is also provided with a door in halves. With the exception of the outer door of the porch the door should neither be painted nor varnished.

Fig. 2 is section through A B, and shows *n*, the ice house, *o*, 9-inch space between the two 9-inch walls. It is provided with a 12-inch iron pipe, *p*, with two branches, each 6 inches in diameter, the ends of which are brought to the external air 6 inches clear of all substances, and closed or opened at will with air-proof valves. The pipes at the bottom of the space are drain tiles, and those immediately above them are those named in *fig.* 1, *k* (they not occurring in the section A B, are introduced to show their utility). The space *o* is, of course, filled with air, and therefore at the period when ice forms the external air will be considerably below freezing-point, whilst that of the space *o* will be above it. From the structure being 6 feet below the surface, it derives considerable heat from it, and will not be influenced readily by atmospheric changes. In the memorable winter of 1860–61 the temperature of the earth at 1 foot was never lower than 36°, that of the atmosphere falling to 3°. In a space of this kind we shall have a temperature at midwinter of not less than 43° to 45°; and as the ice in *n* will melt according to the temperature of the air it is surrounded by, and as it must derive its heat from *o*, we can by displacing the air in it, by opening the valves of *p*, let out air at 43°, and by those of *k* replace it with that at, it may be, 20°. In any case, at the time of filling the ice house, *n*, we should have in *o* a temperature below freezing, the parts surrounding being thoroughly frozen by the coldness of the air of *o*. Were *o* earth it would have a temperature of 40° to 43°, and the ice in *n* would be melted by the air heated by the higher-temperatured surrounding material, of which the heat will keep increasing, until in July it will be from 55° to 60°, afterwards gradually declining to the winter minimum of 43° to 45°. In our case, *o*, or the air in it, can also be warmed by the temperature of the surrounding substance: hence arises the necessity of enclosing it with a non-conductor. I propose, therefore, that we fill *q*, *q*, with very dry sawdust—kiln-dried, if possible, but not browned very much, and put in hard, it not being possible to make it too tight. The sawdust should be isolated from the ground at the bottom of *q*, making over the drain a half circle of "culvert" tiles to keep damp from rising and wetting the sawdust.

Above the ground line it will be seen that our arrangements as regards the exterior are of wood; in fact, we construct over the ice a summer-house, only we fill the interior with ice, and have seats, *r*, *r*, all round outside under cover of the roof; *s*, *s* is lined with deal battens, 4 inches by 3 inches, and covered with half-inch boards doubled; first one thickness close, and then the other upon them, so that the last boards will cover the joints of the first. The sides and roof are done alike, and to give a neat appearance the sides may have fixed on the outside larch poles, sawn up the middle, from which the bark is removed, and when dry varnished. The seats may be formed of like material, also the floor *t* over open area *u*. The supports for the projecting roof are larch poles barked and varnished, the bases of which are slightly elevated on stones, and dowelled in. The roof should be thatched with heather, a foot to 18 inches thick, and if this be done neatly we have a structure anything but unornamental, and invaluable for shelter from storm or heat, and as a resting-place.

But let us return to the interior. The roof of the ice well is of bricks disposed as a semicircle, the ends being also arched to meet the quarter circle of the sides. We do not place earth against the outer wall of the space, *o*, but sawdust, to bear the weight of the bricks composing the semicircle, the weight of which tends to cause the upright 9-inch walls to bulge out. One course below the striking of the arches is some strong angle iron, 3 inches on each side of the angle, and half an inch thick, one side of the angle to be placed on the wall, and covered with a row of headers, and the other side close on the face of the course of bricks on which it is laid. At every 3 feet along the angle iron, and on its exposed face, should be made a hole for an inch bolt, whose outer end must have a 2-inch solid socket, for which a 1¼-inch wrought pipe is prepared to screw on 2 inches. We have in building to put in clamps or straps of 3 inches by half an inch bar iron, with an inch hole 3 inches from the upper end, and the lower to pass through the wall at a foot above the foundation, and to turn up 3 inches

in the space *o*. We put straps in, of course, as the wall is built, and when the angle iron is put on we introduce the bolts through the holes in the straps, and also through the angle iron, securing them with nuts. The head of the bolt being screwed 2 inches, a 1½-inch socket pipe is screwed on, and its other end let into a stone, *r*, that must be on hard ground, which, if not naturally so, must be rammed until it is like iron. These provisions must be made on both sides, and at both ends, so far as doorways will admit. To keep the internal arch firm we place every alternate brick in the course of the outer arch wall on which the angle iron is placed, through far enough to reach the bricks of the other arch. The

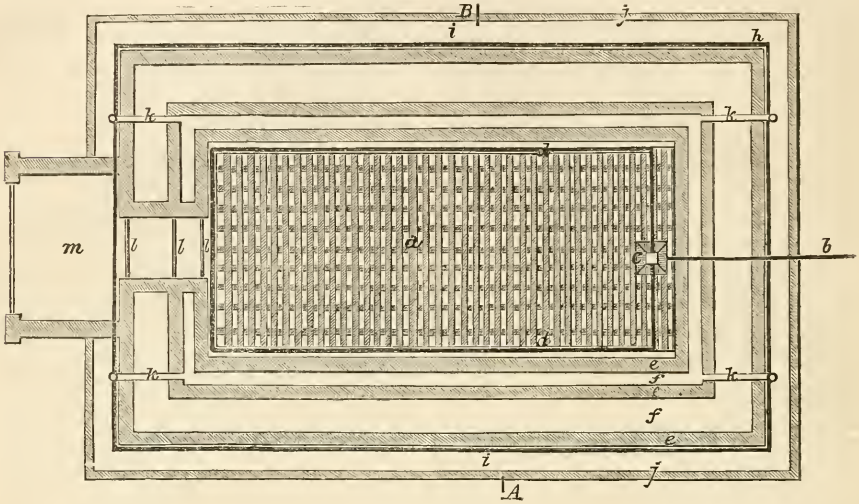


Fig. 1.—Scale 8 feet to 1 inch.

outside of the last arch, or that face next the sawdust, should be plastered with cement, and the internal one also, but inside.

The house as described will hold 172 cubic yards of ice when thoroughly filled, and will preserve it for a long time, though in order to effect this the doors must be closed, and the spaces between each stopped tightly up with dry straw or straw

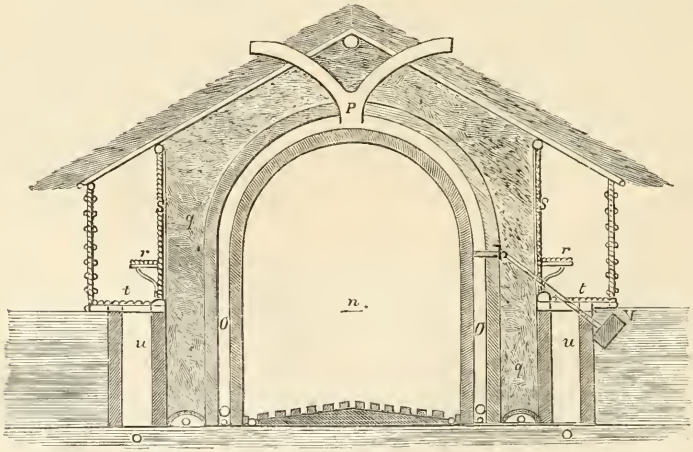

Fig. 2.

shutters, placing one against the other, when it is as safe for keeping as if it were hermetically sealed. It is surrounded with air at a temperature as low as that of the ice, and can derive no heat except through the 2-feet thickness of sawdust The valves are to remain closed, for it is necessary that the air in o be kept still, and to open them would only admit air of a higher temperature. If, however, after filling the house with ice, the weather should be mild for a time, and then be followed by a severe time of frost, it will be judicious to open the valves, and, displacing the air in o, replace it with that at a lower temperature. The valves should be closed when a minimum has been secured, and should not be opened again until

the return of frost the following autumn, when air at a temperature below freezing should be admitted.

Nothing is so detrimental to ice-keeping as constantly opening the doors. It should only be occasioned by necessity, and the doors should be closed after the person visiting the ice chamber, so that as little as possible of the outer air may be allowed to enter, and in coming out the like care should be bestowed on closing the door.—G. Abbey.

CARYOTA EXCELSA.

The subject of our present illustration is a member of perhaps the most distinct genus belonging to the natural order Palmaceæ, inasmuch as it is the only genus which has bipinnate, or, in other words, branching leaves. There are other genera, such as Wallichia and Martinezia, which may be mistaken for Caryota when the plants are in a young state, but as they increase in size it is utterly impossible to confound them with any other family; for while the leaflets of Palms as a rule are long and narrow, tapering upwards and becoming narrowest at the apex, those of Caryota, on the contrary, are very broad at the ends, present the appearance of having been bitten off, and taper downwards towards the base. All the species of Caryota are natives of India or the islands of the Indian seas, and some of them are of immense value to the natives, supplying them with sugar, sago, toddy, and many necessaries of life; and the "kettul" fibre of commerce is also derived from one or more species of this genus.

In a decorative point of view, Caryotas are exceedingly beautiful, especially if sufficient space can be afforded them to develope their beauties, and this is not so very difficult; for although some of the kinds become trees with stately stems 50 or 60 feet in height, there are others that never exceed 18 or 20 feet. In a young state Caryotas are admirably adapted for the decoration of the dinner-table, and also form beautiful objects distributed throughout the various apartments during the summer months, but during the winter I should scarcely advise them to be kept in rooms unless these are slightly heated. When larger they may be plunged in the open air in summer, to assist in giving the pleasure ground a tropical appearance, but, of course, the practical common sense of the gardener or amateur must be brought into play, in selecting a sheltered nook or dell to enable it to withstand any sudden change of temperature, which often, in fact too often, as we frequently find to our cost, occurs with us even in the most favourable seasons.

Caryota excelsa.

This plant, of which we have now the opportunity of giving a portrait through the kindness of M. Rothschild, is one of the best of the genus for decorative purposes, and will amply repay any amount of labour which may be bestowed upon it. It will not fail to give equal satisfaction to the possessor, whether grown in the drawing-room, or in the stove, or used in the open air; in all of these situations it will produce a grand tropical effect, which is always so highly appreciated by lovers of the beautiful in Nature who live in temperate climes.

As a compost for Caryotas, I use good rich loam and leaf mould in about equal parts, with the addition of a little sharp river sand. The pots should be well drained, and during the summer a liberal supply of water should be given. If the plants are kept in the stove during the winter, still continue to supply them freely with water, but this must be given more carefully if the plants are kept in a low temperature. As a rule Caryotas are not easily propagated except by seeds, but they occasionally send up suckers from the base, which should be removed as soon as large enough, potted in some sandy loam, in as small-sized pots as possible, and plunged in a gentle bottom heat until well established.—Experto Crede.

GROS COLMAN GRAPE.

Having seen at page 102 a few notes by Mr. Rivers on this Grape, I wish to state that for the last twelve years I have had ample opportunities of testing its qualities, and I have come to the conclusion that there are few varieties to equal it, not to say surpass it, as a fine late-keeping Grape of excellent flavour. The Vine is of a vigorous strong habit, and a free bearer, both on its own roots and grafted on the Black Hamburgh.

The chief point in the treatment of this variety is to have the fruit ripened early, and in planting I would place it next to the Muscat of Alexandria, then after the Gros Colman I would have Alicante. Gros Colman will compare favourably even with

Lady Downe's for keeping, and in flavour is superior. It will also colour well even without fire heat, which is another point in its favour. I have had it planted in a cool house, but there it is not so much at home, still even in such a house it will do better than many other kinds. The fruit, like that of the Alicante and Lady Downe's, requires to hang, as Mr. Rivers describes, till fully ripe.

Those about planting a vinery for a supply of late Grapes will find the Gros Colman, Madresfield Court, Alicante, Lady Downe's, and Muscat of Alexandria the best varieties for the purpose. A few other Grapes hang well, but I question if there are five to equal these, which are sure croppers, large in bunch, fine in berry, good keepers, and, above all, of strong constitution.—Stephen Castle.

BLUE-FLOWERED HYDRANGEAS.

As we were on a visit to Jersey in company with our colleague and fellow-worker, Dr. Eug. Fournier, we saw some fine blue Hydrangeas in the terraced gardens of the Hotel Royal, the colour of which was a beautiful ultramarine, and distributed in a wonderfully even manner. We noticed that there were some rose-coloured heads among the blue ones, but these were upon much less vigorous subjects. As the blue colouring was always in direct proportion to the strength of the plant, one reasonably comes to the conclusion that the substance which imparts the colour acts at the same time as manure upon the soil, that rose is the colour peculiar to the Hydrangea in a low state, whilst blue would be that of it in a natural or overfed one. The blue colour of Hydrangeas arises from the mixture of certain matters with the soil, and it is upon this practice that the following remarks bear.

In 1857 Mr. Luscombe showed some splendid blue Hydrangeas, which had been grown beneath a group of Firs in the soil formed by their decayed leaves, and by so doing threw open a new field for inquiry, as it had hitherto been thought that blue Hydrangeas could only be produced by means of the following substances, and even then in different degrees:—Lime water, chalybeate water, common red sand, Norwood loam, water in which red-hot iron had been plunged, solution of alum, and iron filings.

To the presence of iron in solution, of lime, and of alum, the action of the above-named materials was thought to be due. Professor Solly, however, proved on trial that lime, alum, or iron, made more soluble by means of hydrochloric acid, or less so by carbonate of soda, were of but little use for colouring plants of the Hydrangea genus; whilst Mr. Fortune, who was unable to obtain blue Hydrangeas by the employment of pure iron, did so by means of alum diluted in water. Now, neither in peat earth nor leaf mould is there any alum to be found. The only explanation of the effect of these soils is that the tannin which they contain is acted upon by the peroxide of iron in the tissues of the plant. The experiment which Dr. Lindley formerly advised can be made by supplying the plants first with water impregnated with peroxide of iron, and then with a weak infusion of tannin.

This, however, is only one side of the case. In 1861 another Englishman brought out the idea that Hydrangeas, so long as they were grown in virgin soil, could be had blue in all sorts of earth. He tried various ways of growing them, and whether it was in an ordinary garden soil or a new and turfy one, the upshot was always the same during five years. Moreover, a plant with rose-coloured flowers and placed in common garden soil, no sooner had reached with its roots the virgin soil which lay underneath, than it began to produce blue corymbs. On the other hand, it is well known that Hydrangeas take on a deep blue colour in granitic, schistose, mica-schistose, and other soils of an igneous origin.

Thus the matter lay, and some new trials of M. A. Gris had thrown but little light upon it, when M. Eug. Fournier set himself to work out some essays in consequence of a dispute which had arisen on this subject at a meeting of the Botanical Society of France. He watered some rose-coloured varieties of Hydrangeas daily, and with equal quantities of the following solutions, beginning on the 1st of May.

1. 20 grammes of ammoniacal alum to a litre of distilled water (175.3 grains to an imperial pint).
2. 20 grammes of sulphate of iron to a litre. Suggested by Dr. Boisduval.
3. 20 grammes of carbonate of copper. Suggested by M. Crockard.
4. Ammonia, quantity not determined.

On the 15th of June, those plants to which ammonia and carbonate of copper had been conveyed by means of water, perished; those treated with sulphate of iron showed decent strength and rosy sepals; whilst those to which the ammoniacal solution of alum had been applied bore a luxuriant growth and large flowers of a violet blue. Of the other experiments made by M. E. Fournier we can speak no further here, but they all tend to show that if iron colour Hydrangeas blue under certain conditions, it also possesses the power of promoting growth like ammoniacal alum. The true cause, therefore, of the blue colour of Hydrangeas is an excessive growth artificially obtained.—(*L'Illustration Horticole.*)

THE GLASTONBURY PEAR.

A few more words may strengthen your opinion, and then I shall have no more to say, I hope, on the Glastonbury Pear until the autumn, when the question ought to be finally settled.

There can be no mistake about the three shoots I sent you—they are one sort—my letter, which was posted the same day, fully explained how they were grown. The balance of opinion points to its being Brown Beurré. On referring to Mr. Scott's descriptive catalogue to the "Beurré, Brown" Pear, every remark there equally applies to the Glastonbury Pear; and had I known Beurré du Roi and Beurré Rouge were the same variety under different names, I should never have troubled you with this discussion.

Many years ago Mr. Chapman told me he had seen his Pear figured in an old work with only one name, Beurré du Roi, and to this day he calls it by that name. You may well ask, Why did I not mention this before, or in 1865? I had forgotten all about it, and it was the reference to Scott's catalogue that recalled it. I have seen the work; it is Batty Langley's "Pomona." Batty Langley was an advanced gardener. He recommends the Quince stock for Pears, Paradise for Apples, root-pruning, and many other practices which I thought modern. On looking over many of my trees, I find on the wall all the shoots are mahogany-coloured and slightly freckled, the smaller shoots on pyramids slightly coloured red and more freckled. If we had had a warm summer to ripen the wood on standards, the wood would have been mahogany-coloured. —John Albert Porch.

SERICOGRAPHIS GHIESBREGHTIANA.

This is a plant more easily managed than its name, and may be grown in a greenhouse. I raised a cutting two years ago in a sunny window, and kept it in a very poor greenhouse after near the window, but the early frost of October, 1870, made it drop its flowers. This year, as soon as I saw flower-buds, I removed it to the middle of the greenhouse, and about a month ago I brought it into a sitting-room. It is now in full flower, being 4 feet high, and each branch with four sets of flowers springing from the base of each remarkably handsome leaf, with which its bright scarlet flowers form a fine contrast. No doubt it could be better grown with a little more heat, but to lovers of flowers, especially in winter, it would form a pretty addition to a greenhouse.—Mary, *Devon.*

DEATH OF MR. WILLIAM RAYNER.

It is our painful duty to have to record the death of Mr. William Rayner, surgeon, on the 26th of January, in the 71st year of his age. Mr. Rayner was a native of Uxbridge, and resided the whole of his lifetime in the town, where he gained a high reputation in his profession, and the respect of a large circle of friends, by his rare intellectual talents and active zeal in every work he considered calculated to promote the interests of the town and its inhabitants. The study of his profession, to which he was devotedly attached, was the chief business of his life. He was a frequent contributor to the *Lancet* and other medical works; his leisure hours were given to the study of natural history, ornithology, entomology, and botany. On these subjects he furnished a series of papers, which were published in the "Cottage Gardener," and which possessed great merit from the popular style in which they were written. Some years ago he prepared a series of lectures on his favourite subjects, which he delivered in Uxbridge, Windsor, Staines, and other towns; these lectures were highly attractive, interesting, and full of useful information; they were profusely illustrated with diagrams and drawings, in the preparation of which a great amount of labour, skill, and time must have been bestowed, in which he was greatly assisted by his talented daughters. He

took great interest in the literary societies of the town, and none ever flourished so well as when he was secretary, some years ago.—(*Uxbridge Marvel.*)

A SOJOURN IN THE HIGHLANDS OF SCOTLAND.

(*Continued from page 59.*)

The fifth day we intended to make a day of comparative rest, being somewhat tired by our Malgurdie excursion the day before. We sauntered about and made ourselves better acquainted with Killin and its surroundings. "Killin" says Dr. McCulloch "is the most extraordinary collection of extraordinary scenery in Scotland, unlike everything else in the country, and perhaps on earth, and is a perfect picture gallery in itself, since you cannot move 3 yards without meeting a new landscape." This is a somewhat overdrawn statement, but true to a certain extent.

There is certainly a great variety of scenery; even the two rivers are different in character. The Lochart comes into the town dashing over rocks, a noisy and boisterous stream; the Lochay silently flows on, and both are wedded together in the placid Loch. The Lochart, as it enters the town, divides into two streams with an island between them; this island is covered with large Scotch Firs, and, we understood, was the burial-place of the MacNabs, but it is a long time (seventy years) since a funeral took place there. The island wore a gloomy and weird aspect.

We were recommended by a friend to call upon Duncan McKye, who sometimes goes out with plant-collectors, and who acted as guide to Professor Balfour and his Edinburgh botanic pupils on the last visit, a few months before we were there. We had a long chat with McKye, who finally accompanied us to the margin of the Loch. We passed the burial ground of the Breadalbane family; it contains the ruins of an old castle, and a handsome mausoleum, in which the late Marquis was laid about two years ago. We saw some magnificent trees, and measured one Silver Fir, 14 feet in circumference, at 4 feet from the ground. We met with thousands of Asplenium Trichomanes, but looked in vain for varieties. We, however, bagged a good form of Asplenium Adiantum-nigrum, and some fine foliaceous Lichens. We afterwards went some distance on the Ben Lawers road, and found Cystopteris dentata and fragilis, also Asplenium Adiantum-nigrum in abundance. We followed a stream up the mountain for about 10,000 feet, but found few plants of much interest. We returned to Killin about eight o'clock.

The morning of the sixth day was gloriously fine, and the mountain summits stood out in bold relief against the sky; even Ben Lawers, the monarch of them all, greeted us bareheaded. Everybody said it would be fine, and we were so confident ourselves that we did not deem it necessary to consult the oracular fat lady, who had proved so true a prophetess a few days before. As we calculated on making good bags, we engaged Duncan McKye to accompany us. We ascended the mountain (Craig Curich) from the Lochay valley, a much longer but a somewhat easier route. We climbed the steep vigorously, then over miles and miles of heather, and at length reached the rocks, and our sport began. The following are a few of the many specimens which we saw and gathered; Saxifraga aizoides, everywhere; S. stellaris, sparingly; S. hypnoides, not plentiful; also a form of it, very like S. platypetala, which we could not determine without inflorescence, and S. oppositifolia, very abundantly; on reaching the cliffs our excitement was intense. The Saxifraga nivalis was somewhat plentiful. To gather this child of the everlasting snow—for it is seldom found much below the perpetual snow-line—is a botanical achievement of no mean order; we had gathered it once before, near the summit of Snowdon about 1855, and its appearance here awakened in us a flood of pleasing recollections. Festuca vivipara was everywhere dangling its long viviparous panicles from the rock; Thalictrum alpinum, plentiful; Lycopodium alpinum, Selago, and selaginoides were also there, likewise the rare Dryas octopetala, Arbutus Uva-ursi, and the two little arctic Willows, Salix herbacea and reticulata. Mr. Mitchell's daring exploits in climbing were rewarded by three plants of the rare Woodsia ilvensis; this was a botanical triumph of the highest order, and we rejoiced greatly at it, as we considered it the best find of the day. Professor Balfour and his thirty botanical pupils had gathered a solitary plant on these cliffs some months before; McKye pointed out the exact spot where the professor had his find. We saw many other rare plants, which we cannot stop here to notice. Our main object was to secure a goodly quantity of the rare Polystichum Lonchitis; this we succeeded in doing, and quitted the cliffs with full bags. We lingered so long on these alpine cliffs that it was dark when we got down to the wooded part of the mountain; but under the guidance of Duncan we finally found the road; and reached our quarters about nine o'clock, much fatigued but highly delighted with the successes of the day.

The morning of the seventh day was very fine; we had asked McKye the day before if he knew the exact spot where the Cystopteris montana was found; he said it was over the shoulder of Malgurdie, in Glenlyon. Mr. Mitchell, full of botanical ardour, resolved to go to the habitat, provided McKye would go with him; to this Duncan agreed, and they started at an early hour in the morning. We accompanied Mr. Mitchell and McKye as far as the bridge over the Lochay, for the purpose of gathering the Lastrea spinulosa, which we had found on our first ascent of Craig Curich. After gathering a sufficient quantity we took a walk up to the bridge over the Lochart, which affords one of the finest views in Scotland.

We rambled down a lane parallel with the river, and soon found the rare Cystopteris furcans. "We would wager," said we to ourselves, "that this is the very habitat in which Mr. H. S. found the plant this summer." We have since ascertained that this was the fact. Just think of our being told that a little plant, not more than 2 inches high, had been found in Scotland without any indication where, and our going and finding the identical habitat! This was a piece of good luck, which no one could possibly have thought would occur.

We went along the road parallel with the Loch for some miles, and then along the margin of the Loch to see what aquatic plants there were in its waters, but we saw nothing except a few lacustrine Sedges of no special interest.

We then ascended some of the hills south of Killin, examined thousands of Lastrea montana, but found no varieties, and returned to the town in the evening. Mr. Mitchell and McKye came back about ten o'clock. They had found some plants of the rare Cystopteris montana in Glenlyon, but were very much fatigued with the long and rough journey. We soon got tea, and then to bed.—(*Extracted from Mr. Stansfield's notes read before the Todmorden Botanical Society.*)

(To be continued.)

ICE-STORING.

In reference to "R. F.'s" communication to you on ice-storing in the Journal of December 14th, page 469, I find, or at least I think, with respect to stacking, that "R. F." writes so as to mislead or discourage those who, like myself, may not have the good fortune to be provided with an ice house. Having had a good number of years' experience in storing ice, both in houses built for the purpose and in stacking, my own experience in this simple matter in the latter case may not be out of place. I will, therefore, give it for the benefit of beginners who may not be better provided for, and those who might wish to enjoy the luxury of iced wines and dishes—to say nothing of the pleasure afforded in giving a piece of ice to assist in alleviating the sufferings of a fellow creature when laid on a sick bed.

Our mode of proceeding is one that has been carried out for a considerable number of years, and is attended with the very best results. After getting the ice in proper working order, and the weather continuing frosty, we begin to take it off the pond and cart it home to the stack, which is built on level ground, but has the advantage of being shaded by trees and bushes from the strong sunshine. We begin the stack by emptying the carts on its foundation; after which there are plenty of hands ready to begin pounding the ice with light wooden mallets sufficiently small to pack all large pieces firmly, thereby excluding from the interior of the stack as much air as possible; this should rather be a little over than under done. I retain the people on the stack pounding away till the whole is finished, and as the ice draws towards a point, one or two drop off as the room for working becomes less, and begin breaking the ice at the bottom before throwing it up to those who remain. As the work proceeds we now and then throw a quantity of water over all, so as quickly to congeal the whole into a solid mass.

We stack in this way from 100 to 110 cartloads every year, and it keeps perfectly well over twelve months, sometimes for a longer period, and we have to open the stack nearly every day during summer.

Before covering-up, if the weather will allow us, we leave the

stack exposed at least twenty-four hours to the frost; if otherwise, we cover it at once. For covering we use dry wheat straw, than which I consider nothing is better; covering not to the depth of 18 or 24 inches, however, but to 18 at least, and all put on at once. We leave no air-pipe through it, and we have no trouble in consequence of its heating or fermenting. We leave the whole in a conical shape, neatly strapped down to carry off the rain. This may be thought a waste of straw by some, but I have found no less thickness of thatching will enable us to attain our object. The straw, however, will not be altogether lost, as a farmer will know well what to do with it, after it has done duty on the stack, when he has his cattle in the fold.

I have no faith in having only twenty or thirty cartloads in a heap, however well protected and stored, or even in a house. My experience is that it is work in vain. Nor would I advise collecting a less quantity than a hundred loads for a stack, if ice is required all the year.

Up to this date (January 29th) the weather has been so open that we have been unable to secure our ice for the season.—J. Fairweather, *The Gardens, Balnagown Castle, Ross-shire, N.B.*

"LES PROMENADES DE PARIS."

One of the most important of the works carried out by M. Alphand in the Bois de Vincennes, was the transformation of Plain of Bercy into the Lake of Charenton. In the centre of this plain, in a valley artificially excavated, an immense

Fig. 1.—Rotunda and Grotto—Isle of Reuilly.

sheet of water covering 120,000 metres has been formed, and its two islands, Bercy and Reuilly, are covered with plantations of large valuable trees, which are of the deciduous and resinous character, and which have been transplanted by means of the tree-lifter. There are also numerous clumps of shrubs and flowers, jetties of easy access to the pleasure boats, two suspension bridges, a rotunda, and grotto (*fig.* 1), a cascade, extensive green swards, pleasing views obtained by piercing vast avenues, and numerous gravelled paths—the whole forming a combination of light and shade, and an example of modern landscape gardening which cannot be surpassed. *Fig.* 2 is a view of the lake taken from the rotunda.

THE FUCHSIA.

It is remarked by the elder class of gardeners that the small and sometimes ill-constructed greenhouses of their younger days often contained a greater number of species of plants than we meet with in the much larger and more

pretentious conservatories of the present day. At that time botanical distinctions rather than floricultural ones were relied on, and a Zonal Geranium was a Geranium and nothing more; while Heaths, Mesembryanthemums, and other genera presented distinctions of a truly permanent character, many of them of a kind that was easily distinguished at all seasons; but fashion of late years has contented itself in a great measure with varieties, so the Geranium and other favourite ornaments of the conservatory have been so divided and subdivided into sections as of themselves to almost fill the house, to the exclusion of other and more enduring members of the same half-hardy family. In other words, the range of cultivation is narrowing,

Fig. 2.—View of the Lake of Charenton taken from the Rotunda.

and I much regret that the compilers of schedules for our great shows do not take means to prevent this by offering prizes for outside objects. I do not mean by that to confine the observation to out-door subjects, but for plants and products seldom met with at shows.

Take, for instance, the Fuchsia. A writer in your number for January 25th very creditably put forth a number of names embracing the best varieties that are known, with some useful observations on them; and although he mentions many names that are strange to me, I fear there are none amongst them that represent the botanical species of Fuchsia, as F. corymbiflora, fulgens, microphylla, and similar kinds, which cannot possibly be mistaken for the hybrids on which cultivators at the present day bestow the whole of their patronage. If I had the framing of a schedule I would make it incumbent on the exhibitor of six kinds to have these three; there would then

be dissimilarity so far as they went, and there are other kinds as well that might be brought into use. Perhaps it may be urged that F. corymbiflora makes a bad specimen plant, but it may, nevertheless, be worked into order.

Many years ago I remember seeing one of the finest flower beds I ever saw, composed entirely of this species, the plants being 7 or 8 feet, and F. fulgens upwards of 6 feet high, and equally well loaded with bloom. The old F. microphylla is rarely met with now, also many other old Fuchsias; but I do know of a plant house where a considerable part of the back wall and some of the roof is covered with that fine variety F. coralina, which flowers more profusely than any of the newer kinds. In the same house F. corymbiflora occupies parts of the rafters, and produces handfuls of its long tubular flowers, so that I often wonder it is not more frequently met with in a like position.

I hope an attempt will be made by some horticultural Society to restore these and other old favourites from the neglect in which they will otherwise soon be buried; those old enough to remember the flourish of trumpets with which these two large-leaved Fuchsias were ushered in, cannot but grieve at the careless way in which they are now treated, while many plants of much less import have usurped their place. I hope those having the arrangement of our great horticultural shows will see to this, and if they can do nothing more in altering their schedules, they might add as a condition to the prize for six, eight, or more Fuchsias, that botanical distinctions and great dissimilarity will be indispensable in order to insure greater variety in this family than has lately been the case. Perhaps Mr. Boothby will be good enough to tell us how far this can be done with advantage.—J. R.

BLACK BESS STRAWBERRY.

Your correspondent, "J. T., *South Wales*," makes inquiry about this Strawberry. I think I can tell him its history. Eight years ago, when gardener to the late S. Rickards, Esq., Shalimar, Acton, who was a Strawberry lover, he bought from Messrs. Butler & McCulloch, of Covent Garden Market, one dozen small plants, telling me, I think, that the kind was raised by Mr. Webb, Calcot, Reading. I planted them in a well-prepared border, and the following summer I layered all the runners in small pots. I had about two hundred of them planted out for fruiting, the rest I potted for late forcing. Those planted out were truly magnificent, bearing from forty to fifty noble fruit on each plant. On many occasions my employer had the small letter-scale brought on the dinner-table to weigh the Strawberries, and I have seen them often weigh down an ounce weight and a shilling. I sent twelve plants for trial to the Royal Horticultural Society's Garden, when the Fruit Committee thought them identical with Empress Eugénie, an opinion which I never shared. Some of the first fruit are flattened or ridged, but the general crop is conical, of a particularly attractive colour, sweet, and refreshing. The potted plants were grown in front of an orchard house and did well.—R. Gilbert, *Burghley*.

REVIEW.

The Gift of Life. A Book for the Young. By Sara Wood. Author of "Children of Other Lands," &c. London: Groombridge & Sons.

The intention of this book—and the intention is realised—is to show children that God is "near them *here*, and with them *now*, giving and sustaining life." In a succession of chapters is shown that Life is everywhere; that it is a great good; how it is sustained; the use of the senses; the need of heat, air and light; the varieties of animal and vegetable life, and many relative topics. It is a wholesome book, and the contents are in simple language that a child may understand.

NOTES AND GLEANINGS.

During last year 3,351,106 eggs and 852,125 cwts. of Potatoes were imported into this country.

—— Mr. William Woolley, gardener to Sir W. Jackson, Bart., Claughton Manor, Birkenhead, died on the 26th ult., aged 54. He was a frequent and successful exhibitor, and was much esteemed in his situation, which he had held for seventeen years.

—— Mr. G. J. Symons, of 62, Camden Square, N., writes to the *Times* on the Rainfall of January:—

"It would be premature to express a decided opinion on the distribution of the excess which has fallen last month; but there seems little probability that additional returns will modify the following deductions:—

"1, The fall at all English stations is greater than the average; 2, The excess is greater at the southern stations, some of which have had more than twice the usual amount; 3, In Scotland, the southern part has had a slight excess, but in the north about the usual quantity has fallen; 4, In Ireland, although at one station the aggregate amount is below the average, it has rained almost every day."

Total Rainfall During January, 1872.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sow, on a gentle hotbed for pricking-out, *Cauliflowers*, *Red Cabbage*, some Early Horn *Carrots*, and hardy *Lettuces*. Sow a pan of *Celery*, and place it in heat. Make a small sowing of Early Dwarf York *Cabbage* on a warm border, and fill up all vacancies in Cabbage and Colewort beds. The surface should be constantly stirred. The ground intended for *Onions* would be benefited by a top-dressing of well-decomposed rich manure, which should be forked-in. When the soil is in a suitable state sow a succession of *Peas* and *Beans*, and between the rows of Peas try a row of Round *Spinach*. *Cauliflowers* under frames and hand-glasses should have attention in giving air, removing decayed matter, stirring the surface, and placing dry earth or charred refuse amongst the plants. Pot a few of the strongest in healthy sandy soil for planting-out. Sow a succession of *Radishes* on a sloping bank or border. Let a dozen roots of *Parsley*, or more, according to the demand, be potted immediately and placed in a vinery at work; when the plants are well rooted supply them liberally with clear manure water. Place a few Ashleaf Kidney *Potatoes* in heat to forward them for planting out when the soil is in a fit state.

FRUIT GARDEN.

Proceed with the pruning and nailing of wall fruit trees when the weather is favourable, and when it is not so prepare material for protecting the blossoms. Pruning Vines out of doors should be at once completed. Cut out old wood from Raspberries, and cut back canes not wanted for fruiting; replace decayed stakes, and tie the fruiting canes neatly to them. Dress the ground with light manure. The thinning and pruning of trees in the orchard may still be continued.

FLOWER GARDEN.

A well-kept lawn is one of the most beautiful features in English pleasure-grounds, but on rich soils the coarse Grasses are difficult to keep under; while on soils naturally poor, and

which have been for some time under the scythe, mosses are found to increase so much as to injure the better sorts of lawn grasses. This is the best time to eradicate them, and a sharp-toothed iron rake or light drag is the best implement for the purpose. It should be worked sufficiently to bring up the moss, which must be cleared off and the lawn left for some time, when the operation may be repeated if necessary. Sow thickly in March Sheep's Fescue Grass and Crested Dogstail, and apply a dressing of sifted lime rubbish and fresh soil, or the latter and fine bone dust. Roll occasionally to keep the ground firm, and a good sward will soon be obtained. Prepare ground for Roses, and if it is poor remove as much soil as possible, and replace it with equal parts of rotten dung and loam. Roses to flower in perfection must have rich soil. Prune stocks budded last autumn, leaving 6 inches of the shoot above the place where the bud is inserted; this portion of shoot will serve as a support when the buds form young shoots in the spring. Prepare for planting Ranunculuses, and if any frosts occur give the bed a turn. There has been so little frost lately, that exposure of this kind has been impossible. Prepare the roots for planting by removing all that are small; these should be immediately planted by themselves, and as but few will flower this year, they will gather strength and size for the next. In arrangement, diversify the colours as much as possible. Examine carefully the stock of Carnations and Picotees, remove every appearance of spot, and if the plants exhibit symptoms of disease, let them be placed apart from the healthy stock. Tulips, Pinks, and Auriculas will require similar treatment to that lately recommended.

GREENHOUSE AND CONSERVATORY.

The conservatory should now be gay with Camellias, Heaths, and Epacrises, Hyacinths and other bulbs from the forcing pits, tree and Neapolitan Violets, Mignonette, Epiphyllum truncatum, Euphorbia jacquiniæflora, Luculia gratissima, Begonias, and, of course, Azaleas, Lilacs, Rhododendrons, and some of the freer-blooming Chinese and Bourbon Roses. Keep a mild slightly humid atmosphere of from 40° to 55°, recollecting that the colder the exterior atmosphere is, the less necessity there is for maintaining a high in-door temperature. In the mixed greenhouse avoid any approach to a high artificial temperature. Place neat trellises to the Tropæolums that are not already furnished with such. Attend in good time to the training, commencing to furnish the bottom of the trellis bountifully; the top will be covered readily enough. The Kennedyas, Zichyas, Hardenbergias, and Gompholobiums should have particular attention in regard to trellises and training; young vigorous plants of Polygala, Muraltia, Pultenæa, Oxylobium, Dillwynia, Eriostemon, Chorozema, Hovea, Leschenaultia, Pimelea, and Epacris, &c., should have all their strong shoots stopped in due time, in order that the plants may form good specimens. Where valuable plants are kept, a stock of the various kinds of loams and peats should always be kept in readiness for potting. For all potting purposes a soft, sandy, yellow loam is to be preferred. Such should have been dug not more than 6 inches deep, with the turf, and after having been stacked long enough for the grass to decay it may be considered as fit for use. Silver sand, rotten leaves, and dry well-rotted cow dung, are all necessary ingredients in different composts. The best peat for Heaths and hardwooded plants is that from Wimbledon and Shirley. With these soils, clean dry pots, crocks of various sizes, and dry moss, potting will go on without interruption. As it is not good practice to water heavily immediately after potting, see that the roots are more moist than dry when turned out. This is more particularly necessary with Heaths and all plants growing in heath soil. Plants should likewise never be potted and cut back at the same time, but the heading-back should precede potting by a sufficient length of time to enable the plant to begin a fresh growth.

STOVE.

If mealy bug exists here, even to the slightest extent, never cease to wage war against it as long as there is the least sign of the insect to be discovered. Perseverance now in this respect will save weeks of toil and annoyance at a season when there is less time to attend to them. After all, perhaps, the sharp eye of a practised workman, with a small brush and copious syringing with tepid water, is the safest, if not the most expeditious, means of banishing these pests. Temperature from 55° to 65°, or lower if the weather is severe.

COLD PITS OR FRAMES.

Frost and damp will, doubtless, have reduced the numbers of some kinds of plants; therefore pots of "stores" which became well established in autumn—such as Verbenas, Fuchsias, Petunias, Heliotropes, Salvias, Calceolarias, &c.—should be removed forthwith to some of the houses or pits to enjoy, if possible, a moderate bottom heat, watering them with liquid manure. These will quickly furnish an abundance of early cuttings, which should be slipped off and propagated at once.
—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Wet, and still wet. Even now it is astonishing what good will be effected by a little surface-stirring of the soil among Cabbages, Cauliflowers, Lettuces, and other crops, if a few dry hours can be obtained for the purpose. All forced vegetables have been very good.

FRUIT GARDEN.

See previous notices, and let beginners be careful that in this dull weather Strawberries are not overwatered.

ORNAMENTAL DEPARTMENT.

We swept and rolled the walks to keep them firm on the surface. We also looked over plants, taking off every decaying leaf, and made arrangements for putting in numbers of cuttings.—R. F.

[We regret that illness prevented our reporter writing more fully.]

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Maidenhair Fern Browned (*Subscriber, Dublin*).—The fronds you sent us are browned, we think from the want of a proper temperature and moisture, the former being too low, and the latter too great. Keep up a temperature of 55° to 60° at night, but with the soil moderately moist, but do not syringe overhead at this season, nor overwater. Remove all the old fronds down to the roots, and repot early in March.

CELERY FOR EXHIBITION (*A Subscriber*).—The best White Celery is Sandringham Dwarf, but Seymour's Superb White is larger. Of Reds two of the best are Hoodt's Imperial Dwarf and Ivery's Nonsuch; but if it be size you require then Laing's Mammoth and Ramsay's Solid Red. The Sooty Qua Cucumber does not require different treatment to that of other frame Cucumbers, being sown in a hotbed of 70° to 75°, and planted out singly in a two-light frame.

VEGETABLES FOR EXHIBITION (*T. Adam*).—From the description we should think that against Mr. Laxton's new Peas, and especially Superlative, none of our old Peas will stand a chance. We would recommend it and Emperor of the Marrows (Williams); of Broad Beans, Monarch Long Pod, and Windsor; of Beets, Dell's Crimson, and Pine Apple Short-top; of Carrots, James's Intermediate Scarlet, and Red Surrey; of Onions, Nuneham Park and Danver's Yellow; and of Potatoes, Red-skinned Flourball, and Giant King.

ROSE CUTTINGS (*M. W.*).—The cuttings struck in a pot during autumn we should repot, either singly or in fours, and place them in a cold frame with the soil just moist, and give them abundance of air. After March, or when they are growing more freely, they will need more copious supplies of water. Old standard Roses may be safely transplanted now in mild weather, and pruned-in rather closely early in March, or, better still, from the middle of November to that of December. Large clumps of the common White garden Lily may now be transplanted. They should be taken up with a good ball, and if divided, as much root and soil as possible preserved to each part. The earlier they are planted the better if the weather is mild.

POTATOES AND PEAS FOR EXHIBITION IN AUGUST (*Subscriber*).—Potatoes, Ashtop Fluke, Headley's Nonpareil, Birmingham Prizetaker, Cambridgeshire Kidney, Prince of Wales, and Lapstone, all kidney sorts. Round sorts are Giant King, Main Crop, American Peach Blow, Milky White, Red-skinned Flourball, and The Queen's. Peas, Laxton's Superlative, Williams's Emperor of the Marrows, Maclean's Best of All and Premier, Laxton's Supreme, and Hundredfold. You did not say how many kinds you required, so we have named half a dozen kidney and round Potatoes, and half a dozen Peas.

HEDGE NEAR THE SEA (*H. H.*).—There is none equal to Elder, so far as we know. We would plant not less than two rows of it on the outside, about 2 feet apart, or a hedge with two rows 2 feet, and the plants 1 foot apart. Rooted cuttings may be had at a cheap rate per 1000. Outside this again we should plant Sea Buckthorn at 2 to 3 feet apart, and then plant common Broom and Gorse or Whin freely in a good width of ground, or sow seeds of the two last. The sowing of Festuca rubra or Creeping-rooted Bent Grass, and Agrostis vulgaris or Creeping-rooted Bent Grass, is right. The hedge inside the enclosure we should plant with Beech 2 to 3 feet, by 12 inches apart.

SEA-KALE WEAK (*Cambria*).—The strongest is to be had from the youngest plants or those two or three years old. The ground should be well trenched, plants or those two or three years old. The ground should be well trenched, manured, and mixed with sand and leaf soil if it is at all heavy. Early in March plant them out in rows 2 feet 6 inches apart, and at a distance of 18 inches in the rows. It is well to surround the roots with sand, especially if the soil is heavy and the ground wet. Plants may be forced with soil at the close of March, and again at the end of May, at the rate of 1 lb. to 3 square yards, and watered with liquid manure from the middle of May to the close of August, as often as it seems necessary. The leaves should not be removed but left to die down first, and then you may begin to force—that is, in November. The cause of your not having a continuous supply is due to your starting too many at once, and not following up with fresh. Begin with a dozen pots at the end of November for Christmas, or even a little earlier, and keep on with a dozen every fortnight or three weeks up to March, after which they will come naturally, the pots merely requiring to be covered with litter or leaves to exclude air and ensure blanching. When two years old the plants ought to be very strong.

PRUNING ROSES IN POTS (*J. W. L.*)—The Maréchal Neil and Gloire de Dijon Roses one year from the bud we would now cut back, if very strong to five buds, and if only moderately so to two or three. Prune Tacsonia splendens on the back wall of a greenhouse, cutting out the last year's shoots, and encouraging the short and young. An inverted turf is good for placing on shelves which are to hold Strawberries in pots for forcing.

ZONAL PELARGONIUMS—VARIOUS (*Adonis*).—Six Zonals to be pinched in summer for late-blooming are Annabel, Duchess, Blue Bell, Lord Chancellor, Penelope, and Comet. Pans containing an inch of drainage, an inch of rough compost, and the rest of fine soil—two parts loam, one part leaf mould, and half a part silver sand—are those in which Myosotis seed should be grown. Cover the seed lightly, water gently, and place the pan in a cold frame near the glass, but shaded from the bright sun to lessen the need for watering. When the plants are well up, water them moderately and keep them near the glass. Harden them well off when they are in the rough leaf, and prick them off into a shaded position out of doors when they are large enough to be handled. For winter flowering in a greenhouse and for raising from seed Primula sinensis vars. fimbriata alba, fimbriata rubra, fimbriata striatiflora, and kermesina are excellent, and also Cyclamen persicum and coum. There are few crops that may be put in between January 1st and May 13th to be cleared by the latter date, indeed we know only of Spinach, Radishes, and Lettuce from autumn-sown plants. Radishes will stand a winter as mild as the present has hitherto been with litter spread over them in severe weather. Plums are budded on the wood of the previous year, or stem of the stock about 6 inches from the ground. If you can get wood of the current year strong enough it will answer as well as on older wood to bud on.

WORMS IN POTS (*Subscriber*).—Stop the holes in the pots while they are soaked for three hours in lime water. This may be made by placing 1 lb. fresh lime in a tub and pouring three gallons of water over it, stirring it up well, and allowing it to stand until the thick part has subsided, when the clear water is drawn off for use.

MELON-GROWING IN GREENHOUSE (*An Amateur*).—If you wish to grow Melons your house must be cleared of all greenhouse plants but those that require the same temperature as Melons do. The wood box over the kitchen boiler will answer, but it should be 8 instead of 5 feet long, to give root room for two plants instead of one, and 10 feet by 3 feet at the top. The box should have plenty of holes, with rubble over them, and 2 or 3 inches deep of rubble at the bottom, covered with 1 foot of good strong loam. As to kinds, Gilbert's Improved Victory of Bath, green-fleshed, and Royal Ascot for scarlet-fleshed will suit you.

LILIUM LANCIFOLIUM RUBRUM TREATMENT (*C. Thorne*).—The plants potted in November and now in a cold frame, should remain there until they have shoots 2 to 3 inches long, and then should be top-dressed with rich soil. After this they should be removed to a cool airy part of the greenhouse, where they will have plenty of light, or be grown in a cold pit if head room can be given them. They cannot have too much air, so long as they are kept from frost, nor should they be nearer the glass than 6 inches. Water thoroughly when the soil becomes dry. Give weak liquid manure twice a-week during the growing and flowering period, and keep the plants clear of insects.

ORNAMENTAL PLANTS IN POTS FOR OUT OF DOORS IN SUMMER (*C. B. E.*).—Channrops excelsa, Dracæna australis, Phormium tenax, Aralia Siebold, and its variegated variety, Seaforthia elegans, Abutilon Thompsoni, Agave americana variegata, Sonchus Saundersi, Yucca filamentosa variegata, Y. aloifolia variegata, Y. quadricolor, and Bambusa gracilis. Humea elegans (a biennial), and Ficus elastica are good.

VARIOUS (*Q. Q.*).—By sprinkling common salt between each layer of leaf soil 9 inches in thickness, so as to make it white, and by turning it over again within a week, and thoroughly mixing plenty of quicklime with it, this fungus may be destroyed. We highly approve of placing autumn-struck Geraniums in a frame, and surrounding the roots with soil, and tying them up with moss. Datura Huberiana is a good plant for placing on lawns with shrubs. It requires now to be sown in brisk heat, and to be grown in a good heat, so as to have the plant strong before planting-out. The seeds germinate more freely if steeped before sowing for some hours in water of a temperature from 90° to 100°.

PRIMULA JAPONICA FROM SEED (*D. M.*).—The directions for sowing this are the same as for Myosotis, and may be seen above. The imported seed is often six or eight months in germinating, or even more, so do not lose patience, but keep it in a cool place until it comes up, and then admit admit abundance of air; keep the plants near the glass, and give enough water to keep the soil moist. When of sufficient size prick them off into small pots, grow them in a cold frame or cool airy shelf in a greenhouse, and shift them into larger pots as they advance. Shade them from the bright sun in summer, but give them lights and air in winter. It appears to be hardy. The young Oleander whose flower-buds did not expand last year will flower this year in May if you place it first in a warm house, and later on in an ordinary greenhouse; so let the bunch remain.

HARDY ORNAMENTAL PARK TREES (*J. P., of York*).—For planting in parks it is necessary that the trees be 8 feet in height, well staked, and secured against cattle. Mountain Ash, Common Beech, Purple Beech, Horse Chestnut, Double Red and Double White, also Scarlet Horse Chestnut, Spanish Chestnut, Wych Elm, English Elm, Lime, Norway and Scarlet Maple; Oak, English, Turkey, and Scarlet; and Sycamore are suitable for this purpose; also Thorns as standards, which have a good effect. As your position is very much exposed, and the ground is suitable to them, we should plant principally Beech and Sycamore, which with us in a very bleak situation are the best of all. If you have a wet spot plant Birch, Poplars, and Alder.

PEACH AND NECTARINE TREES GUMMING (*Constant Reader*).—If your trees are growing in rich or damp borders they will make strong late growths, and gumming is inevitable. If the border requires draining, see that this is done, so that there may be no danger from stagnant water near the roots. If you can obtain well-decayed turfy loam, lift the trees and replant them, using a large portion of the loam about the roots.

PLUM TREE OVER-VIGOROUS (*R. E. M.*).—For all kinds of fruit trees we believe more in judicious summer-pruning than transplanting. The vigorous shoots you speak of should have been stopped twice during the summer; this treatment would have given you half a dozen less vigorous shoots, which would have furnished the wall with bearing wood. We would not advise you to replant the tree now; cut back the shoots to half their length, and in summer, when the tree is making young wood, pinch back the shoots that are inclined to be vigorous.

CONSERVATORY (*Leamside*).—In stating no shelf should be opposite the plate-glass window, we merely referred to the narrow shelf or platform continued all round the sides. There would be no necessity for breaking the line of this shelf if this window were not made into a door. Of course we like to have the stage opposite to be filled by the best showy plants. The square-cut laths will answer very well for a pathway, but will not be so elegant as iron grating. The heating pipes will be out of the way under the stage. You are quite right as to the arrangement of the piping, but take care that the air-pipe is fixed at the highest point. It is of little importance whether you take that pipe out of doors or not. We should think that 4 or 5 feet in height would be ample. The end should be bent down, so as to form a semi-circle, to prevent dust, &c. getting into it. We presume that you have a supply-cistern of some sort, taking cold water to the bottom of the boiler, and that this is higher than the highest part of the pipes. If you want bloom all the winter, you had better have three pipes instead of two all round under the stage.

MANAGEMENT OF MUSCAT VINES (*Constant Reader*).—Turfy loam of a calcareous nature, taken from an old pasture, with the addition of some crushed bones, is the best compost for Vine borders. If it is clayey loam add mortar rubbish. The time to start the vinery will depend on the time at which the Grapes are required, but Muscats are not generally grown for early crop. Start the house about the 1st of February; a temperature of 45° at night will be sufficient at first, gradually rising it to 55° at night by the time the buds have pushed an inch. The heat must now be gradually increased until an average night temperature of 70° is attained.

VINERY RAFTERS AND ROOF ANGLE (*R. Brace*).—We think the fall of the roof will be quite sufficient, but we should have judged better if we had known the height of the wall and wall plate in front. We think the rafter sash bars the height of the wall and wall plate in front. We think the rafter sash bars 4½ inches by 1¼ will do, even for 26-oz. glass at 14 inches apart. We would have three rafters 3 inches wide instead of 1½ inch, one at each end and one in the middle, in order to tie the house more securely. Then we would run an iron bar, 1 inch wide and a quarter of an inch thick, longitudinally about the middle of the roof, screwing this bar to each rafter sash bar, which would keep them all steady in their places. Two small neat columns against this bar would make all still more secure, and would be no great eyesore.

PROPAGATING CASE FOR A WINDOW (*An Amateur*).—As you dislike to go to the expense of the propagating cases advertised, to stand in a window, your best and most economical plan would be to proceed as follows:—Make a stout box 34 inches long, 17 inches wide, 13 inches deep at front, and wooden case 34 inches long, 17 inches wide, 13 inches deep at back, the bottom to rest on a table, or itself be the bottom of a table. The wood should be from 1 to 1¼ inch thick. We would have the top moveable, in two squares of glass, so as to reverse the upper and lower sides at pleasure to prevent drip. You may line it all inside with zinc or tin. What is essential is to have a box or drawer at the bottom, securely lined, with no small holes. Have an opening by which to fill that vessel or drawer with hot water; not full, however, but say from 2½ to 3 inches, so that there will be no

danger of the water running over, and there should be a tap or plug to draw off the water when cold. The heat may thus be regulated to a nicety. We should prefer the covering-plate without holes in it. It would be best to put the cuttings in small pots; you may pack round them cocoa-nut fibre or clean sand. Such a box will hold eighteen 48-sized pots, and thirty-two 60-sized pots. A second case would be useful for hardening-off the young plants.

Earth Closets (*E. C.*).—There is no doubt about the desirability of these. None have surpassed Mr. Moule's. We cannot discuss the subject, so we send you a pamphlet by to-day's post.

Conifer Seeds (*Scote*).—Write to some of the principal seedsmen who advertise in our columns.

Hautbois Strawberry—Rockery—Magnolia grandiflora (*H. A. B.*).—The culture of the Hautbois Strawberry is the same as that of others. The runners should be well rooted, placed in rows 2 feet apart, and at a distance of 18 inches from plant to plant. We grow it in beds separated by alleys 1 foot wide; each bed is 4 feet across, and holds three rows of plants, the two outside ones being 9 inches from the edges, and the centre one midway between them; the plants are at a distance of 15 inches apart. After fruiting the centre row is taken out, and the two others allowed to remain until the second or third year. We think Royal Hautbois is the best kind. We know of no book specially devoted to the formation of rockeries. The Magnolia against a south wall will not flower until it becomes strong. One of the size you name might do so in about three years.

Ixora Leaves Spotted (*X. E.*).—The spot on the leaves is caused by damp or water on a late growth. It appears as if after syringing water had rested on the leaves in drops for some time. Cease to syringe. Give more heat and air in moderate quantity, and the leaves will come all right. Keep up a good amount of moisture by evaporation, either by means of a trough or by sprinkling the floors, or both.

Roses Planting (*W. M. A. W.*).—In planting standard Roses the "crown of the roots" should not be covered more than 3 or 4 inches with soil. Deep planting is not, however, the cause of your plants going off, but it is due to the union of the Rose with the stock not being complete, there being some Roses very liable to go off, especially on the Briar. We do not know of a remedy. Soapsuds may be given to Roses, but only during the growing period, and as they hold a considerable amount of soda, should be diluted with twice the quantity of water when strong. Use liquid manure for the Roses, and apply the soapsuds between the rows of Cauliflowers, &c.

Rhubarb Forcing (*Unfortunate*).—Rhubarb cannot easily be forced in the ground in time for the 1st of January, but it may be done. Cover the stools with pots or boxes 2 feet 6 inches deep, and take a trench out on both sides of the row or rows, about 2 feet wide and deep; fill this with hot dung, heaped up a foot around the pots, at the close of November, and then you ought to have Rhubarb by New Year's day. The dung should be in a high state of fermentation, and should retain its heat for a month, being replenished with fresh as it settles. For early work it is by far the best plan to take up the roots and place them in a Mushroom house, or any place having a temperature of 55° to 60°. Royal Albert is a good kind for early forcing, and ours in the open ground, under 6 inches of litter, has stalks 6 to 8 inches long, whilst none of the other sorts have done more than swell at the crowns.

Raising Perennial Phlox (*T. M.*).—We have never experienced much difficulty in raising perennial Phlox seed, and should advise you to try again. Sow the seed in good sandy loam, in gentle heat; but by all means avoid peat, as it is apt to cake and get hard, thus seriously affecting the seed.

Potatoes Sprouted (*Bucks*).—The sprouts of the Early Rose, if less than an inch long, should not be removed, but the tubers should be kept in a cool place safe from frost, and planted with the sprouts on. If the sprouts are more than an inch in length, it will be necessary to remove them, when the tubers will sprout again by planting time. Ours have sprouted about half an inch, but by keeping them one layer thick on lath shelves, and giving them plenty of air, we shall retard them until a month is past, and then plant them. The best preventive of disease is early planting, so that the Potatoes may mature before the late summer rains. Lilium auratum's flowering power does increase yearly. We had bulbs in 1870 with five flowers, which in 1871 had thirteen flowers, and are now throwing up very strong shoots. Our "Window Gardening for the Many" will suit you, and may be had free by post from our office for 9½*d*. Cyclamen persicum seed is what you will require to order. If sown now in a hotbed, and in autumn removed to a house with a temperature of 45° to 50° it will flower finely next winter. If you procure, say, a five-shilling plant of Lapageria rosea, it will in all probability flower the first year, or, if you raise it from seed, the third year.

Rats Scratching up Red-leaded Peas (*F. S.*).—Melt some lard and mix it with oatmeal, so as to form a crumbling paste, and lay it three nights by their haunts. On the fourth mix some poison with the paste. In the meanwhile we should mix some gas tar with ashes, merely impregnating them with the tar, so as to become crumbly, and sprinkle the ashes over the rows. This will puzzle both them and mice; but poison is a much more certain remedy.

Geraniums in Winter (*Carolus*).—Select some of the best of the plants at bedding-out time for this purpose. Pot them into 6-inch if in 4-inch pots by the close of May, place in a frame, giving plenty of air, and keep all flower-buds and the points of the shoots closely picked off. From May to the middle of August they may be stood out-doors in an open sheltered situation on coal ashes, and early in August put into 8-inch pots, having been stopped a fortnight previous. After potting place them in a cold pit or a frame, giving them abundance of air, and in the third week in September remove them to a house with a temperature of 45° to 50° at night, where they will flower for some time. The flowers should be picked off up to the beginning of September. Good sorts for late flowering are Baronne Haussman, Beauty of Dulwich, Crimson Perfection, Cramoisie Superieure, Coldstream, Duke of Edinburgh, Sunlight, Mademoiselle Nilsson, Blazer, Cremorne, Queen of Nosegays, and Douglas Pearson.

Name of Fruit (*Belton House*).—Golden Winter Pearmain.

Names of Plants (*C. Bennett*).—1, Selaginella cuspidata; 4, S. Kraussiana; 2, Pteris serrulata; 3, P. cretica albo-lineata; 5, P. argyræa; 6, Adiantum hispidulum. (*Surrey*).—Chrysanthemum frutescens, *L.*, a native of the Canary Islands. It has become tolerably common during the past five or six years. (*H. Wilson, Helperby*).—We recommend you to sow your seeds and send us examples of the plants when in character. One appears to be a species of Acacia, and is remarkable for its long orange-coloured funicle; the other most probably is some of the Liliaceæ, say Urginea.

POULTRY, BEE, AND PIGEON CHRONICLE.

LIGHT BRAHMAS.

Since my last remarks concerning this beautiful breed of poultry I have had an opportunity of carefully examining the

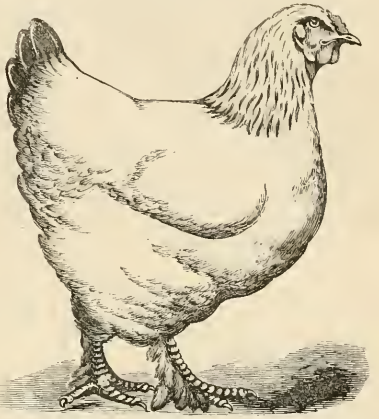

Fig. 1.

classes at the great shows of the year, and have also read the letters of Mr. James Long and my old friend (though we have

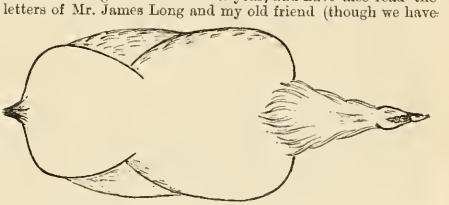

Fig. 2.

never yet met face to face) "F. P.," of Yorkshire, some of whose Dark Brahma blood is in my own yard. I have pur-

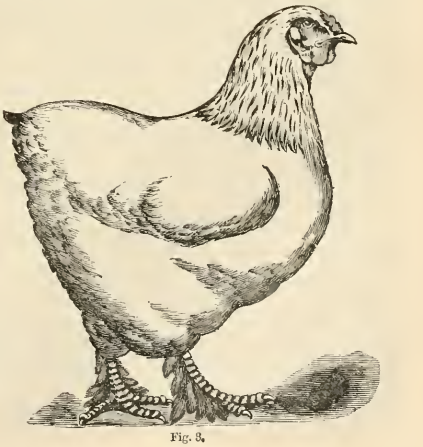

Fig. 3.

posely let the subject rest awhile, though longer than I had intended, from pressure of circumstances; but as I have a great admiration for this really splendid variety of fowls, which I am still compelled to say has greatly degenerated, I wish now to point out where I think improvement is needed, and the special faults to be guarded against by breeders. I, of course, give them as my views; I cannot commit, nor would I if I could, any judges or breeders to my opinions; but at the same time I have reason to believe that our principal judges fully agree. And I would remark that the special instances of judging pointed out by Mr. Long and others really prove little or nothing, and manifest a very small knowledge of what judging is. Many things may interfere with a bird repeating any given success, and many different birds may be brought against him. Not only shape and colour, but size, carriage, condition, comb, slipped wings, leg-feather—all have to be considered; and a wise man will rather consider the average of a judge's awards, and endeavour to form a sort of analysis for himself, than pin his faith to any particular one at a leading show, where commanding excellence in one or more points may have diverted attention from very serious faults which afterwards become apparent.

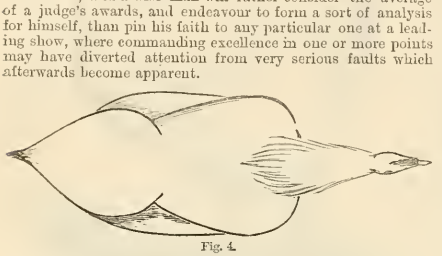

Fig. 4.

Mr. Long in his letter states again that the Lights "are and always have been, in this country at least, much inferior in frame, and cannot be made to attain the size of their more fortunate rivals;" and again, "It appears to me that one variety is naturally larger than the other." I do not think Mr. Long has been a breeder of Brahmas long enough to make such an assertion, and I am quite sure he has not been a breeder of fowls long enough yet to give him any right to sneer, as he does in his last paragraph, at any facts, or effects of strongly marked features, which others think they have observed in their own yards. When he has bred longer he may find that no law affecting the female imagination is absolutely uniform; that some individuals may be affected by the same circumstances under which others are not; and that effect may be not at all marked in its character, and yet very real. I only mention this because I object to the tone of assumption which Mr. Long takes throughout, and I proceed to say that during the past show season several birds have been taken out of pens at my request, and I can assert that many cocks have been shown over 12 lbs. These cocks have all been pure-bred, and though in all but one case bad in colour, it conclusively proves that there is size enough to be got, and that the dissociation of size and good colour, now so universal, is simply owing to the bad judgment of the breeders.

Mr. Long next doubts my remark that if birds are shown good in shape, colour, and feather "they will win, even if not large." I simply say that at the Palace the second and third cockerels (the last Mr. Long's own bird and very small), at Birmingham the first-prize cock and second and third-prize cockerels, were such birds. As I have already said, any particular bird winning or not winning proves nothing; and while, as at present, it is colour *versus* size, there must always be many apparent contradictions. Neither bird being all good, it is a comparison of two very serious faults, and not till size and colour are shown generally in the same birds can the Lights expect to compete favourably with the Darks. When this is the case—and it may be—I am quite sure they will hold their own; but while the very best chickens are sent out and stunted by early shows, I fear we shall not see it to any great extent.

But the foundation of all real improvement must be correct shape, and hence I wish to explain more particularly what I, at least, mean by "duck-shape," as contrasted with the contour of the true Brahma. The latter is, perhaps, the neatest and most compact-looking fowl of any—of any large breed unquestionably. It has, or should have, a good fluff and a broad and ample cushion. I speak of pullets. Neither, of course, is so full as in the Cochin, the Brahma being properly a much closer-feathered bird; but a good cushion there should be, broad over the tail, but rising more and more to the very last, where it merges harmoniously into the line of the nearly upright tail. Such an outline is presented in the diagrams on page 133 (*figs.* 1 and 2), and which represent the true shape as it actually exists in high-class birds.

But in looking at any Light class of pullets we shall find many birds which utterly fail to conform to this type. There are Dark birds, too, which fail in it, as I freely admit; but while I myself exceedingly object to such taking prizes, it must be remembered that whenever they do there is almost always extraordinary pencilling, which catches the judge's eye and condones the fault in shape, while the white of the other class affords no such counterbalance. Still, the fault is at least three times more general, as I carefully noted at London and Birmingham, than in the Dark classes, and the sketches (*figs.* 3 and 4), were made from a Palace bird, which was a fair type of about fifty single pullets in the class. In some there is literally no cushion at all, but in others, as in my sketches, it does appear to start out well over the wings. But, alas! the "early promise" is not kept; as it gets towards the tail it becomes narrower and narrower, so that viewed from the top the pullet appears widest across the shoulders and gradually tapers off to the tail, giving the bird a triangular instead of that square compact shape which the other type presents.

Looked at sideways the same fault will generally be found. In place of the rising Brahma cushion and nearly upright tail, the little cushion there is starts up too fully, and then gradually droops, the tail itself being nearly horizontal. Of course, in some cases the fault will show from the top and not from the sides, or *vice versâ;* but the two as drawn commonly go together, and are what is meant by "duck-shape," being analogous to the formation of the Aylesbury Duck.

In the cocks the same fault will be found. The saddle may start well, but gets narrow over the tail or does not form a nice rise to it, and the whole bird is narrow behind. Broad-saddled cocks were more numerous this season, as I was glad to observe, but are still much more rare than in the Dark classes.

In breeding Light Brahmas, then, we want to get back generally, not in exceptions merely, the neat compact shape of the true breed. We want to get back the heavy leg-feather, yet with soft hocks, which so many Dark birds now have. We want to get a distinct jet black stripe in the hackle, and we want to get all this combined with the grand size, which belongs properly to the one as to the other. I need not say how it is to be done. Breeders only need to keep the desired points carefully in mind, and they will speedily procure them, and will be fully able to compete fairly and honourably with those of us who, from want of pure country air and grass, are forced to cultivate only the no less beautiful Dark breed.—L. Wright.

LAST YEAR'S JUDGING.

I think few of my friends will say that I am in the habit of grumbling without cause, but complaints in your Journal as to the judging are now so frequent, and the dissatisfaction so widespread, that I think the question ought not to slumber, but something ought to be done to improve the present system in the coming season.

I have never before this publicly complained of the Judges, for, considering their work and the onerous duties they have to perform, it is almost impossible for them not to make some mistakes; but really the mistakes that I have seen this season by some of our acknowledged Judges have been so glaring that I think an importation of a little fresh blood would be an advantage. No doubt they are set to do too much; but surely, for their own sakes, it would be better that before accepting the office they should inquire the number of pens likely to be exhibited, and refuse to act unless there are sufficient Judges appointed, rather than that such awards should be given as were made last season.

As your readers are aware I exhibit nothing but Dorkings, and with some Judges unless the birds are dark they stand no chance. Others favour large frame irrespective of colour, and in this I think they are right, for I hold that a Dorking (not Silver) may be any colour but black and white; and that there are as heavy birds and as good birds light as well as dark, and if we are to breed to colour, we must lose size, which is the very essence of a Dorking. Now this is one of those things that occur at almost every show, and I have several times seen a superior pen beaten simply because it was light in colour.

I merely mention this as an instance, but it is not half so glaring as many awards that I have seen in Dorkings the last season. They have been so peculiar, to say the least, that I have made up my mind that if next season they are as bad, I shall retire from exhibiting entirely, though I hope never from breeding. I have heard breeders of other kinds express themselves in similar terms as to the judgment of those kinds, but I speak of the only kind that I profess thoroughly to understand.

As to amateurs exhibiting by themselves, all I can say is that I should consider I disgraced myself if I could not compete, and successfully (of course, not always so), with the best breeder or exhibitor in the kingdom, be he amateur or dealer; and I am sure if any amateur will only use a little judgment and keep to one breed alone, he will soon find that he can win in any company. But there is also another consideration which I think of very great importance—namely, that were it not for dealers buying birds from amateurs to exhibit, many amateurs, who at the end of the year find a nice little balance in their favour in their poultry account, would find themselves debtor to cash. In my own case dealers are amongst my best customers, and I find they give as good a price as anyone, and I invariably send birds on approval to them, but unless I know the amateur I always decline. Dealers know the value of birds; many amateurs do not. If we debar dealers from exhibiting their custom will soon cease.

I like free trade in the poultry exhibition as well as anywhere else; but I do ask for and expect good decisions, which certainly have not been the rule during the past season. I write with the best intention, and without wishing in any way to hurt the feelings of any of our Judges; but I hear so many complaints expressed, and that from many of our most eminent breeders and exhibitors, that I hope the subject may be thoroughly ventilated, and some means adopted to improve the present system of judging, which is deterring, and will, unless improved, deter many of our best breeders from exhibiting at all. I know I am treading on very delicate ground, and should not have touched upon the subject at all but for the complaints that have appeared in your Journal, which I consider are just, and require the immediate attention of the committees of our shows.—T. E. Kell.

WHAT SHOULD REGULATE CLASSES? POLANDS' CRESTS.

A few weeks ago the secretary to one of our poultry shows made a remark which I humbly think requires a rejoinder. Of classes which are badly represented at some shows, he remarked that fanciers of those sorts of birds should exhibit their fowls in strong numbers if they wish them to have more classes allotted to them. Now I cannot help thinking that this is rather more than can be expected of the generality of exhibitors. Suppose a case at a certain show. There are four if not five classes for Hamburghs; at the same show there is one class for Polands, of all ages and of all colours. Now, is it fair to expect so numerous an entry, or of such good quality, in the one class of Polands, which would include White-crested Black, Golden, Silver and any other colour, as in the four or five classes of Hamburghs? I certainly cannot persuade myself that it is. In my opinion Polish fowls at all our first-class shows should have at any rate six classes allotted to them—viz., two classes for Goldens, adults and chickens, the same for Silvers, and the same for any other colour. Then, and not until then, will Polish fowls have justice done them. If with this classification they still came up in small numbers, I should say such liberal treatment ought not to be expected in future. If it be said that it has been tried and has proved a failure, I answer, Yes, but several years ago when Polish fowls were scarce, and when they were supposed to be only an ornamental fowl, and a very tender and delicate breed too. Now they are much more extensively kept than formerly, and I think my brother fanciers will corroborate what I say when I affirm, as I do most fearlessly, that the Polish fowl is extremely hardy, and one that is very easily reared.

I will now just advert for a moment to a point on which I expect a little contradiction; that is, whether the largest-crested Polish fowls ought, on account of their immense crests, to take prizes in preference to smaller-crested birds which are more correct in their markings and richer in colour. I think that they should not, if the smaller-crested birds are much superior in marking and colour, and have decent crests; for, although the crest is the principal feature in the Polish fowl, yet I do think that brilliancy of colour and correctness of marking are very important points, and I should certainly prefer to sacrifice a little in crest, if by so doing we could gain in the other points named.—G. W. Boothby.

ANY OTHER VARIETY OF BANTAMS.

In answer to your correspondent "Fair Play," it has long been my opinion that it was time to have separate classes for Black and for Any other variety of Bantams. Further, a well-known breeder and exhibitor of Black Bantams said to me at Birmingham Show, that he never would show any more unless there were a separate class for Black Bantams, and I nearly made up my mind to do the same. If I so resolve, I think committees of shows will miss my name in the Bantam classes, as I show about seventy pens of Black Bantams in the year. I consider that the extraordinary merits of the Black Bantams entitle them to a separate class, and the same may be said of the White and Laced Bantams, though the latter two are not shown in such large numbers, but they would be if encouraged the same as some of the large breeds—for instance at Birmingham and Wolverhampton Shows in 1870 and 1871, of White Bantams there was an entry of fourteen and fifteen pens respectively, and I am certain there will be a large entry of Whites this year at Wolverhampton. Why? Because good prizes are offered.

If committees will only offer good prizes, I think owners will make plenty of entries, and I hope that the committees of our shows will follow the example of Birmingham, Leeds, and Newport. I will send to all shows where there are separate classes. If there are two or three shows on the same day, I cannot, of course, exhibit at all of them, but I will send to those with the most liberal prize list. I do not like to see exhibitors in the Variety class for Bantams paying an entry fee of 5*s.* to compete for a prize of £1, while exhibitors of other breeds can compete for a £2 prize for the same entrance fee. When classed by themselves these Bantams always muster a good entry, indeed I never saw a Black Bantam class a failure. Our leading Black Bantam breeders should do their best to have separate classes for our pets—the prettiest of all fowls.—R. H. Ashton.

WOLVERHAMPTON POULTRY SHOW.

The sixth annual Meeting of this Society took place in the Agricultural Hall, Wolverhampton, on the 2nd, 3rd, and 5th inst., and was a most extraordinary success. The Show was of great excellence, and the first bright beams of sunshine that have been noted in this district for five or six weeks placed beyond question the pecuniary success of the undertaking. Considering that the earliest moment the Hall can be placed at the disposal of the Directors of the Show is after the Wednesday's market is closed, and that the whole of the fittings have to be erected, and the specimens all penned and ready for the Judges early on the Friday morning, the public being admitted at 2 P.M., it must be admitted that the arrangements have to be made most expeditiously; and they were most effectually carried out under the able superintendance of the Hon. Secretary, Mr. Barnett.

The Show embraced collections from most of the principal English breeders of poultry, and prizes were awarded to Pigeons that had actually been sent from Amsterdam. These birds proved to be of varieties never before seen in the United Kingdom, and as a matter of course from their great novelty excited much attention. The number of entries of all descriptions nearly reached 1200, or three hundred more than last year. There was the customary display of the best of Cochins, Brahmas, Dorkings, and waterfowl in the empire; many very valuable lots were, however, breaking up very rapidly in constitution from constant exhibition. It was stated in the Exhibition that some of the very best birds had actually never passed three nights together at their owners' for some months past, "but had been travelling constantly from show to show, and had earned for their owners tenfold their cost price, though it appeared at the time of purchase so large." Some of these birds were evidently so emaciated as to suggest the probability of their never being able to last out the season.

In the *Game* classes, on the contrary, the most brilliant condition and robust health prevailed in almost every instance, in the majority of cases the Game fowls shown being quite unaccustomed to the exhibition pen, and they were such as are rarely equalled for tightness of feather and robust constitution. In these classes, by referring to our appended prize list it will be seen Mr. James Fletcher, of Stoneclough, almost monopolised the prizes with grand exhibits, worthy of the successful issues of that gentleman's yards in their most palmy days. It is evident by their attractiveness at Wolverhampton that Game fowls

are still objects of much interest and admiration in this district, which some quarter of a century back was so noted for them. *Turkeys*, *Geese*, and domestic *Ducks* were among the best features of the Exhibition; and in waterfowl kept simply for their exquisite beauty of feather and general liveliness of character on artificial waters near private suburban residences, the Show stood equal to any. This class proved so large and well filled, that at the request of the Judges an extra prize was willingly granted, and even then scarcely a pen remained not fully worthy of prizetaking. In this division Buenos Ayrean Ducks were first, Mandarins second, and American Summer Ducks third on the prize list. The class for any variety of Bantams except Game, and almost all the classes for French fowls, were among the best in the Show, and excited much attention from their novelty in this neighbourhood.

DORKINGS.—*Cock.*—1, L. Patton, Taunton. 2, Miss Davies, Chester. 3, J. Martin, Claines, Worcester. *hc*, Miss Davies; — Robinson, Garstang; J. L. Lowndes, Harlsweld, Aylesbury. *c*, H. Tyler, Birmingham.

DORKINGS.—*Hens.*—1, L. Patton. 2 and 3, J. Martin. *hc*, Hon. J. Massey, Limerick; N. Russell: Rev. G. H. Biggs; Rev. E. Bartrum, Berkhampstead; Dr. Hewson, Coton Hill, Stafford; C. Speed, Exton, Oakham. *c*, A. Darby, Bridgenorth.

COCHIN-CHINA (Cinnamon and Buff).—*Cock.*—1 and Extra, H. Lloyd, jun. 2, Mrs. Allsopp, Bindlip Hall, Worcester. 3, H. Lloyd, jun., Handsworth. *hc*, W. A. Burnell, Southwell, Notts; W. A. Taylor.

COCHIN-CHINA (Cinnamon and Buff).—*Hens.*—1, Mrs. Wilkin, Bootle. 2, A. Bamford, Middleton. 3, W. A. Taylor. *hc*, H. Lloyd, jun. (2); W. A. Taylor; H. Tomlinson, Gravelly Hill, Birmingham; Mrs. Wilkin.

COCHIN-CHINA (Brown and Partridge).—*Cock.*—1, T. Stretch, Ormskirk. 2, E. Tudge, Whitchurch. 3, W. A. Taylor.

COCHIN-CHINA (Brown and Partridge).—*Hens.*—1 and 2, W. A. Taylor. 3, J. K. Fowler.

COCHIN-CHINA (White).—1, W. A. Taylor. 2, R. S. S. Woodgate. 3, R. Smalley, *hc*, Mrs. A. Williamson, Leicester; R. Smalley, Lancaster. *c*, A. J. E. Swindell, Heathland, Stourbridge; R. S. S. Woodgate, Pembury, Tunbridge Wells; Mrs. A Williamson.

BRAHMA (Dark).—*Cock.*—1, T. F. Ansdell, Cowley Mount, St. Helen's. 2, B. F. Parrott. 3, W. A. Taylor. *hc*, Dr. Holmes, Whitecotes, Chesterfield; Master J. Gamoo, Chester; A. Rigg, Sevenoaks; E. Pritchard, Tettenhall. *c*, Lady Tankerville, Chillingham Castle; G. F. Whitehouse, King's Heath, Birmingham; Mrs. Bailey, Longsight.

BRAHMAS (Dark).—*Hens.*—1, T. F. Ansdell. 2, E. Pritchard. 3, J. Watts. *hc*, Earl of Shrewsbury, Ingestre Hall; A. H. Etches, Market Drayton; H. B. Horrell, Caermarvon, Clyro; H. Yardley, Birmingham; A. Rigg; J. Watts. *c*, O. E. Creswell; G. F. Whitehouse.

BRAHMAS (Light).—*Cock.*—1, W. T. Storer, Brewood. 2, H. Draycott, Hinnbertstone, Leicester. 3, Mrs. A. Williamson. 4, J. A. B. Dean, Chepstow. *c*, Mrs. A. O. Worthington, Barton-on-Trent; J. Benton, Erdington (2); C. Morris.

BRAHMAS (Light).—*Hens.*—1 and 2, J. R. Rodhard, Wrington. 3, F. Crook, Forest Hill. 4, H. Dowsett, Plesbey. *hc*, Mrs. A. O. Worthington; Mrs. A. Williamson; J. Beach, Wolverhampton; T. A. Dean. *c*, Rev. M. Rice, Bramber Rectory

HOUDAN.—*Cock.*—1 and 3, R. B. Wood, Uttoxeter. 2, D. Lane, Hardwick, Gloucester. *hc*, Mrs. J. Cross, Appleby Vicarage, Brigg; J. C. Cooper. *c*, Lady Tenterdale.

HOUDANS.—*Hens.*—1 and 2, R. B. Wood. 3, W. Dring. *hc*, Rev. C. B. Rowland; D. Lane. *c*, Mrs. Harding.

CRÈVE CŒURS.—*Cock.*—1 and 3, R. B. Wood. 2, W. Dring. *hc*, J. K. Fowler, Aylesbury; Mrs. Wilkin; R. B. Wood. *c*, F. Bennett.

CRÈVE CŒURS.—*Hens.*—1, R. B. Wood. 2, C. H. Smith, Radcliffe-on-Trent. 3, J. C. Cooper, Limerick. *hc*, E. Pritchard; Mrs. Wilkin; W. Dring, Faversham; J. K. Fowler; J. J. Maiden.

SPANISH.—*Cock.*—1, Hon. Miss D. Pennant, Penrhyn Castle. 2, E. Jackson. 3, J. Walker. *hc*, Mrs. Allsopp; E. Jackson, Pinchfield; J. F. Sillitoe, Wolverhampton; Miss E. Browne. *c*, Mrs. Allsopp; E. Gill, Redland, Bristol.

SPANISH.—*Hens.*—1, J. Thresh, Bradford. 2, J. F. Sillitoe. 3, Hon. Miss D. Pennant. *hc*, Hon. Miss D Pennant; E. Jackson; J. Walker, Sandeford; J. F. Sillitoe; F. Gill. *c*, H. Beldon, Bingley; E. Jones; H. F. Cooper (2).

GAME (Black Red).—*Cock.*—1 and 2, J. Fletcher, Stoneclough. 3, G. R. Smith, Scarborough. *hc*, J. Walker, Wolverhampton; J. Mason, Worcester; G. Bagnall, Drayton, Cheadle; W. Speakman.

GAME (Brown Red).—*Cock.*—1 and 2, J. Fletcher. 3, G. Clement, Birmingham. *hc*, G. Lucas, Mansfield; G. F. Ward, Wednesbury, Nantwich; J. Oldfield, Bradford. *c*, Earl of Shrewsbury; W. Dunning, Newport.

GAME (Except Black or Brown Red).—*Cock.*—1, S. Matthew, Stowmarket (Duckwing). 2, J. P. Gardner, Rugeley (Duckwing). 3, J. Fletcher (Duckwing). *hc*, G. Mace; G. Heyfforder.

GAME (Any variety).—*Hen.*—1, J. Fletcher. 2, S. Matthew. 3,—Basaington (Piles, *hc*, J. Forsyth (8); J. Fletcher. *c*, Earl of Shrewsbury; J. Fletcher; C. H. Kyle (Duckwing); C. W. Brierley.

HAMBURGHS (Gold-pencilled).—1, J. Buckley. 2, H. Beldon. 3, J. Roe, Badfield. *hc*, Duke of Sutherland; C. Parsons. *c*, T. May & Son; E. F. Gardom; T. Walker, jun.

HAMBURGHS (Silver-spangled).—1, Duke of Sutherland. 2, H. Beldon. 3,—Allsopp. *c*, R. Bailey, Etwall, Derby.

HAMBURGHS (Gold-pencilled).—1, Duke of Sutherland. 2, H. Beldon. 3, G. Ashpole, Etwall. *c*, A. Smith, Northowram; C. Parsons; C. Bloodworth.

HAMBURGHS (Silver-pencilled).—1, H. Beldon. 2 and 3, Duke of Sutherland. *hc*, J. W. Edge, Erdington.

HAMBURGHS (Black).—1, N. Marlor. 2, Rev. W. Serjeantson, Acton Burnell. 3, C. Parsons. *hc*, C. Parsons, Whitmore Reans; T. Bush, Bristol; R. Bailey; Rev. W. Serjeantson. *c*, R. Beldon; C. Sidwick, Peddleden Hall, Keighley.

BANTAMS (Game).—1, Clews & Adkins. 2, G. Heafford. 3, Miss Swindell. *c*, J. Oldfield.

BANTAMS (White, Clean-legged).—1 and 2, Rev. F. Tearle, Gazeley Vicarage, Newmarket. 3, R. H. Ashton. *hc*, H. Beldon. *c*, R. Pickles, Great Hey; H. Draycott.

BANTAMS (Any variety except Game and White).—1, M. Leno, Markyate Street (Laced). 2, Master F. St. Ridgway (Black). 3, Rev. W. Serjeantson (Japanese). Extra Prize, W. Cutler, Worcester (White Booted). *hc*, Mrs. Woodcock (White Japanese); Master F. W. Ridgway, Dewsbury (Black); J. H Bradwell (Black); E. Cambridge, Cotham, Bristol (Black); P. Pigott (White Booted); H. Beldon (Booted); Rev. G. F. Mansell; Fetherton (Sebright); W. W. Bonlton (Cuckoos); M. Leno (Laced); H Beldon. *c*, Ladies Moreton (White Japanese); H. Draycott; E. Cambridge (Black); Mrs. A. O. Worthington (Black); Duke of Sutherland; T. Bush (Cuckoos); W. W. Boulton, Beverley (Cuckoos).

ANY OTHER VARIETY.—1 and 2, H. Beldon. 3, Rev. A. G. Brooke, Shrawardine (Malays). *hc*, T. Dean (Golden Poland); W. Jackson, Blakedown. Kidderminster (White-crested Polands); H. Frankland (Cuckoo Cochins); W. Hill, Heaton Moor (Cuckoo Cochins); R. S. S. Woodgate (Silkies); F. Wilton (Black Cochins); Rev. G. F. Hodson (Malays).

SELLING CLASS.—*Cock.*—1, Mansell (Spanish). 2, W. A. Taylor (Buff Cochin). 3, J. Bloodworth, Cheltenham (White Cochin). 4, C. Bloodworth (Buff Cochin). *hc*, O. E. Creswell (Coloured Dorking); Rev. G. F. Hodson (Coloured Dorkings); H. Lloyd, jun. (Buff Cochin); H. Tomlinson (Buff Cochin); J. Bloolworth (White Cochin); J. Sichel (White Cochin); Hon. Miss D. Pennant (Dark Brahma); G. A. Stephens (La Fleche); J. K. Fowler (La Fleche); W. Tippler (Houdan); F. Bennett (Crève-Cœur); J. Walker (Spanish); E. Jackson (Spanish); J. Fletcher, Stoneclough, Manchester (Game); J. Forsyth (Black Red); Duke of Sutherland (Golden-pencilled Hamburgh); T. Boulton (Golden-spangled Hamburgh); J. Buckley (Golden-spangled Hamburgh); H. Bagshawe (Black Hamburgh). *c*, Mrs. E. Williams (White Dorkings); J. Bloodworth (Buff Cochin); H. Tomlinson (Buff Cochin); T. Sisney (Partridge Cochin); Hon. Miss D. Pennant (Spanish); J. Clements (Game); Missea Wilson (White Malay); Capt. Downman (Silver-spangled Poland); J. P. Gardner.

SELLING CLASS.—*Hen.*—1, E. Jackson (Spanish). 2, H. Lloyd, jun. (White Cochin). 3, Rev. G. F. Hodson (Dorkings). 4, T. Bush (Black Hamburgh). *hc*, W. A. Bornell (Buff Cochins); A. Darby, Bridgenorth (Buff Cochins); H. B. Morrell (Dark Brahma); J. Sichel, Timperley (Buff Cochins); E. Ryder, Hyde, Manchester (Dark Brahma); Hon. Miss D. Pennant (Dark Brahma); J. A. B. Dean (Light Brahma); M. Leno Markyate Street (Light Brahma); E. Pritchard (Crève-Cœur); Miss E. Browne (Spanish); H. Biower (Spanish); J. Mansell, Longton (Spanish); S. Stephens, jun., Ebley, near Stroud (Game); J. Widdowson, Meynell Langley (Silver-spangled Bamburgh); T. Yateman (Silver-spangled Hamburgh); F. Boulton (Golden-pencilled Hamburgh); G. F. Whitehouse (Golden-pencilled Hamburgh); C. Pumley (Golden-pencilled Hamburgh); T. Bennett (Black Hamburgh); W. Cutler (White-booted Bantams); *c*, N. Russell, Bryngwyn, Oswestry (Coloured Dorkings); R. W. Beachey, Kingskerswell (Dorkings); J. Robinson (Dorkings); H. Lloyd, jun. (Buff Cochin); R. Thompson (Dark Brahma); R. M. Lord (Dark Brahma); G. Ashpole, Etwall (Golden-pencilled Hamburgh); A. Darby.

TURKEYS.—1, F. Lythall, Banbury. 2, N. Russell. *hc*, W. Tippler, Chelmsford.

GEESE.—1, J. K. Fowler. 2, J. Watts. *hc*, W. Tippler.

DUCKS (Aylesbury).—1 and *hc*, J. K. Fowler. 2, T. Hedges. *c*, Misses Wilson, Woodhorn Manor; T. Hedges.

DUCKS (Rouen).—1, J. Wright. 2, W. Stephens. *hc*, J. K. Fowler; Rev. H. J. Stokes, Grindon Rectory, Leek; H. B. Smith, Bromilton, Preston.

DUCKS (Any other Variety).—1, G. S. Sainsbury, Devizes (East Indian). 2, M. Leno (Mandarin). 3, J. Watts (Carolina). *hc*, Lady Tankerville (Shellorakes); J. E. Morris (Pintail, Carolina, and Mandarin); Rev. W. Serjeantson (Pintail); N. Russell (Carolina); R. H. Ashton (Mandarin); H. B. Smith (East Indian and Mandarin).

PIGEONS.

TUMBLERS.—*Almond.*—1, J. Ford, Mookwell Street, London. 2, J. Fielding, jun., Rochdale. 3, J. Ford. *Any other Variety.*—1, J. Ford. 2, J. Fielding, jun. 3, R. G. Teebay, Ormskirk.

CARRIERS.—1 and 3, W. Siddens, sen. 2, H. Yardley, Birmingham. *hc*, S. Holroyde, Manchester.

POUTERS.—1 and 2, Mrs. Ladd, Calne. 3, H. Yardley. *c*, J. Duncan, Walsall.

FANTAILS.—1 and 2, H. Yardley. 3, J. W. Edge. *hc*, J. F. Loversaidge; A. A. Vander Meersch, Tooting.

ANTWERPS.—1, R. Wright, Hockley. 2, H. Yardley. 3, J. Robbins, Wolverhampton. *hc*, S. A. Taylor, Sutton Coldfield; H. R. Wright. *c*, C. Copeman. *Working or Homing Antwerps.*—1 and 2, H. P. P. Price, Casile Madoc, Brecon. 3, R. Pritchard, Ludlow. *c*, Hon. G. Lascelles, Leeds.

DRAGOONS.—1, W. H. Mitchell. 2 and 3, J. Watts. *hc*, T. Robson.

JACOBINS.—1, J. Thompson, Bingley. 2, F. Waitt, King's Heath, Birmingham. 3, H. Yardley.

ANY OTHER VARIETY.—1, H. R. Wright (Barbs). 2, W. Cneopkoopman, Amsterdam. 3, H. Yardley. 4, H. Draycott, Humberstone, Leicester. *vhc*, J. Thompson (Helmets). *hc*, T. A. Dean, Marden, Hereford (Black-headed Nuns); H. Yardley; W. Arkwright (White Frill-back); J. Fielding, jun. *c*, J. E. Morris, Elmsdale, Wednesbury (Ice); W. Cneopkoopman; S. Holroyde.

SELLING CLASS.—1, J. Thompson. 2, H. Yardley. 3, H. R. Wright (White Dragoons). *hc*, C. Laagman, Bilston (Antwerps); J. W. Edge (Barbs). *c*, T. Robson (Turbits and Magpies); W. Choyce; J. W. Edge.

JUDGES. — *Poultry:* Mr. Edward Hewitt, Eden Cottage, Sparkbrook, Birmingham; Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. W. B. Tegetmeier, Finchley, London; Mr. H. Allsopp, Birmingham.

DUNDEE POULTRY SHOW.

THE first Show of poultry was held in the Kinnaird Hall, Dundee, on the 1st and 2nd inst., and as far as regards the quality and number of specimens it was a success. The Hall, a handsome building, is one of the best there could be for the purpose. The pens used were those of Mr. Fothergill, of Sunderland, and the arrangement and management of the Show, though in few hands, was very good.

All the *Dorkings* in the Dark-Grey class were very good, and the cup for the best pen of any colour was awarded to the adult bird. It is seldom that so perfect a pen of adult Silver-Grey Dorkings is seen as that which was first in its class, though both classes contained good birds. Adult *Spanish* were of fair quality, and the young birds were very fine. The first-prize pullet was a model. Adult *Cochins* in both classes were very poor, but the chickens were good, the cup being awarded to a pen of Buffs, in which the cockerel was strikingly handsome. In *Brahmas* the cup went to a sound-coloured pair of chickens, and the competition in this class was very close. Of *Game* there were large and good entries, the competition being severe in all classes. In single cocks a Brown Red of high quality was first, and Black Reds second and third. Following these were the Red Game hens, the first of which was a Black Red, very sound in flesh and tight in feather. Among Game cocks of any other colour, an extremely good Pile cockerel was first, and the cup for Game cocks was awarded to him, the second and third-prize birds being Duckwings. In the class for hens Dnckwings won all the prizes. *Hamburghs* were shown the Spangled in one and the Pencilled in the other class, Silvers in both cases carrying-off the first honours, and the cup for the section also. In Game *Bantam* cocks there were no less than forty entries, and the competition was keen, the first-prize bird being a Black Red, perfect in all points; and the cup was also awarded to this bird. The second-prize bird was fine in shape, but a little short of colour; the third-prize one was good in all points, but larger than the rest. There were many others also worthy of notice. Of hens there were twenty-four pairs, but they did not show to the same advantage as the cocks, doubtless

on account of the approach of the laying season. The first prize went to Piles, and the second to Black Reds, the latter being somewhat out of condition, though of very good quality. In the class for Any other variety, the first and third prizes went to Sebrights, and the second to Blacks. In the Variety class for other poultry, Silver Polands were first, Black Hamburghs second, and Crêve-Cœurs third.

In *Ducks* the Aylesburies were a good class, but the Rouens were not equal to them. The Selling class contained forty-three entries of birds of good quality and of most varieties.

Dorkings (Coloured except Silver-Grey)—1 and Cup, J. W. Will, Errol. 2, D. Gellatly, Meigle. 3, Mrs. A. Bruce, Meigle. *hc*, A. Bowie, jun., Carnoustie. *Chickens*—1 and 2, W. Langlands, Dundee. *hc*, J. W. Will; T. Raines, Stirling; A. Bowie, jun.; G. Allen, Balhary, Meigle; D. Gellatly.

Dorkings (Silvers).—1, Mrs. M'Donald, Forres. 2, M. Edwards, Hilton, Alloa. 3, D. Annan, Cupar, Fife. *Chickens*.—1, T. Raines. 2, J. Turnbull, Falkirk. 3, J. W. Will.

Spanish.—1 and Cup, H. Wilkinson, Earby, Skipton. 2 and 3, A. Shepherd Meigle. *hc*, Mrs Abels, Alith. *Chickens*.—1 A. Shepherd. 2, J. W. Will. 3, H. Wilkinson. *hc*, W. Leslie, Sellardyke. *c*, A. Bowie, jun.; W. Paterson, Langholm.

Cochin-China (Cinnamon or Buff).—1, J. W. Will. 3, Miss Drummond, Meginch Castle. *Chickens*.—1 and Cup, J. C. Jameson, Newton-on-Tay. 2, T. Stretch, Ormskirk. 3 and *hc*, J. W. Will. *c*, A. Barnett.

Cochin-China (Any colour except Cinnamon and Buff).—1, J. Stephenson, Tillyfour. 2 T. Stretch. *Chickens*.—1, T. Stretch. 2, W. Fraser, Aberdeen. 3, J. Stephenson. *hc*, Mrs. C. Wilson, Broughty Ferry; W. Smith, East Newport.

Brahmas (Any colour).—1, T. F. Ansdell, Crowley Mount, St. Helens. 2, Lieut-Col. C. Rice, Cupar. 3, Miss Morrison, Kirkcaldy. *Chickens*.—1 and Cup, J. Stuart Scoaringbarn. 2, R. Brownlie, Kirkcaldy. 3, J. W. Will. *hc*, T. Raines; D. Annan; H. White.

Game (Black and Brown Red).—*Cock*.—1, H. M. Julian, Hull. 2, J. Mason, Worcester. 3, J. Dick, Dunphail. *hc*, J. W. Will; J. Allan; Henderson and Campbell, New Deer; R. Stewart, Kelty; N. L. & T. H. Herriot, Kirkcaldy; T. Mason, Green Ayre; J. Mollison, Meigle; J. W. Will. *c*, J. W. Will. *Hen*.—1, J. W. Will. 2, L. Casson, Ulverston. 3, T. Mason. *hc*, J. Dick; Henderson and Campbell; J. Carlisle, Earby; A. Stephen, Blairgowrie.

Game (Any other colour)—*Cock*.—1 and Cup, J. W. Will. 2, H. M. Julian. 3, Morris & Woods. *hc*, J. Anderson, Kirkcaldy; W. Baillie, Monifieth. *Hens*.—1, Earley, Ridmarley. 2, H. M. Julian. 3, J. W. Will.

Hamburghs (Spangled)—1, J. W. Will. 2 and 3, G. & J. Duckworth, Church. *hc*, J. W. Will; R. H. Ashton, Mottram; W. R. Park; Mrs. Brown, Crieff. *c*, D. Harper, Fogvieley, Lochee.

Hamburghs (Pencilled).—1, Cup, and 3, J. W. Will. 2, W. R. Park. *hc*, Mrs. Chalmers; A. Pratt.

Game Bantams (Any colour).—*Cocks*.—1 and Cup, R. Brownlie. 2, J. Barlow, 3, Morris & Woods. *hc*, J. W. Will; G. Todd; R. Brownlie (2); Miss J. M. Frew; J. Dobson; Bellingham & Gill; R. Youll; J. Scott. *c*, J. Scott; J. Mollison; J. Henderson. *Hens*.—1, R. Brownlie. 2, G. Todd. 3, Bellingham & Gill, Woodfield, Barnley. *hc*, J. Abel. *c*, J. W. Will (2); R. Youll, East Boldon, Sunderland; Miss R. C. Frew, Kirkcaldy.

Bantams (Except Game).—1, T. Watson, Freeland Bridge of Earn. 2, R. H. Ashton. 3, Miss B. P. Frew. *c*, J. Watts, King's Heath, Birmingham (2).

Any other Variety.—1, W. Bearpark, Ainderby Steeple. 2, A. Pratt, Kirkcaldy. 3, W. R. Park, Melrose. *hc*, G. G. M'Laren, Broughty Ferry; Mrs. J. F. White, Castle Hunter.

Ducks (Aylesbury).—1, Lord Kinnaird. 2, J. W. Will. 3, J. Stephenson. *hc* Lord Kinnaird; J. Mollison. *c*, R. Dickie, Burnside; H. White.

Ducks (Rouen).—1, J. Mollison. 3, J. Stephenson. 3, A. Bowie, jun. *hc*, W Wilson. *c*, A Simpson.

Selling Class.—1, W. Paterson. 2, Lord Kinnaird. 3, J. Stevenson. *hc* Miss Drummond (2); A. Bowie, jun.; W. Leslie; W. Smith; D. Gellatly; J Mollison; Mrs. Harvey, Edinburgh. *c*, J. Taylor, Montrose; Mrs. J. F. White A. Shepherd.

The Judges were:—For Dorkings, Cochins, Spanish, and Brahmas, Mr. Teebay, Preston; for Hamburghs, Bantams, Variety class, Ducks, and Selling class, Mr. Hutton, Pudsey. The Game were judged jointly.

FALKIRK POULTRY SHOW.

This Show, which took place on the 2nd and 3rd inst., was by far the best ever held in the locality, this result being mainly due to the tact and energy of the Hon. Secretary, Mr. D. H. Roberts, who, after finding the Society in debt last year, determined to carry it on till success should be attained, and we are happy to state that both in point of numbers and pecuniary results this object has been accomplished. The Corn Exchange, where the Exhibition was held, is well suited for a poultry show, the light being well diffused and abundant. The arrangements were all that could be desired, and the pens used were those of the Royal Gymnasium at Edinburgh, and with the backs covered with boards they answered the purpose well. We understand, as they are let for hire, that it is the intention of the proprietor to provide canvas backs, thus preventing damage to the birds, so much complained of of late.

Adult *Spanish* were only moderate in quality, but the young made up for them, most of the cockerels being of high merit, though the best pullet was a very young bird in the third-prize pen. There were four pens of *Dorkings*. The cup was awarded to a good pen of Dark birds shown by Mr. Raines. *Cochins* were a mixed class; the first prize went to Buff, and the second to White. The Buff cocks being very good in colour, took the cup from the *Brahmas*, of which there was a large but only moderately good display. *Hamburghs*, with the exception of the winners, were but poor. The special prize was awarded to Silver-spangled, but the decisions would no doubt have been different if Messrs. Ashton & Booth's pen had arrived in time. *Polands* were very good, and Blacks won the special prize; Golden were second, and Silvers third. With the exception of the winners of the timepiece, the Red *Game* were not good, but these were all that can be wished for both in feather and soundness of flesh. In Duckwings the hens were superior to the cocks; and in this class the so-called celebrated pen of Mr. Harley's was left out on account of a large part of the lower and underpart of the cock's hackle being out. The following letter was exhibited above a pen of Game belonging to Mr. Little. It had been sent to Mr. Hutton, one of the Judges:—

"Dickstrer, Longtown, Carlisle, January 18, 1872.

"Sir,—I see you have been judg at Selkirk, and I hav been I of the suc-cessful exebetrs. I most Thank you kindly For your kindy returns you showed towards My Birds. I have just entered them For Falkirk Poultry Show if you Think they will dow any thin thar. I onld Lik the tim Peese at Falkirk its For the Best Pare of Game so if you judge thare Let me know and i shal go Shares with the money Prize For you cindens your Respectfully Ricrd. Little, Dickstrer, Longton. *P.S.*—Please Write."

The pen was disqualified, and we wish that all poultry committees would resolve never to allow the writer of that letter to exhibit.

In the Variety class grand Crêve-Cœurs were first, Scotch Greys of extraordinary merit second, and Silver-pencilled third.

There were some large and well-shown *Turkeys* and *Ducks*.

There were thirty entries of Game *Bantams*, and the competition was keen. The first and third prizes went to Black Reds, and the second to Duckwings. The Bantams in the Variety class were unusually good; Blacks being first, Pekins second, and Silver Sebrights third. Both Selling classes were well filled, and many of the birds changed hands.

Of the *Pigeons*, the Pouters measured well, and in style and carriage were all that could be desired. Blue Pied were first, White second, and Black Pied third. Fantails were fair, as also the Jacobins. In Tumblers, the Almonds were first and Black Mottles second, both kinds being very good. Of Carriers there were some well-shown birds; the winners were all Black. There was a large entry in the Variety class. The first prize went to a nice pair of Letz, the second to Black Trumpeters of high quality, and the third to a pretty pair of Blue Foreign Owls. In most of the classes special prizes were offered by tradesmen, and these were awarded to the first-prize pens.

Spanish.—1, R. Somerville, Edinburgh. 2, J. Duncan, Carron. 3, W. C. Hardie, Carron. *hc*, D. M'Heath, Bridge of Allan; J. Craigie, Fordell. *Chickens*.—1 and Special, W. C. Hardie. 2, H. L. SELLING CLASS.—1, E. Robinson, Airdrie (Pouters). 2, J. G. Dunn, Newcastle-on-Tyne. 3, J. E. Spence, Bromghty Ferry. *hc*, J. Gait; J. Frame (Pouters).

JUDGE.—Mr. E. Hutton, Garden House, Pudsey, Leeds.

A REMARKABLE INCIDENT.

WITHIN the last two years I have had three consignments of beautiful variegated fancy Pigeons from abroad, at once handsome, novel, and valuable. Amongst the first collection I received was one bird of a rather singular variety of Pigeon, a match to which, I think, is not to be with in Great Britain, and I am also inclined to think that the variety is not common in any country. A small space will suffice for a brief description of her peculiarities. In general outline she is much after the character of the Jacobin; her feathering is of a deep glossy black throughout except the tail, which is pure white; the head is small and unusually round, for it is a proper round head, and is partially covered from behind by a close-fitting hood, which terminates abruptly at the sides of the neck; the beak is very short and black. The eye is a pure white, and surrounded by a thin, fleshy, blackish-red lash; the eye, therefore, from its extreme whiteness and brilliancy is most conspicuous by its surroundings of intense black. Another peculiarity, which is only observed on close inspection, is, that she is minus the little oil-gland immediately above the tail. I have had six other Pigeons from abroad with the same peculiarity, therefore I am not surprised at this somewhat extraordinary feature.

This funny little Pigeon came to me direct from Turkey, for I helped them all to land, and I was vexed to find only one of the variety, for a pair were shipped to me, but the cock bird died on the voyage. I reached home safely with my birds and placed them in a warm place prepared for their reception, but I resolved on putting this oddity with my stock of Antwerps, and giving her entire liberty. In due course out she came and seemed perfectly satisfied with her English home, and fed, flew, and bred with my Antwerps for the season, but unfortunately only one young one was the issue of her alliance with the mate she made choice of. That young one was a fac-simile of herself; but notwithstanding my watchful eyes, and her tender care—for she is a capital feeder—it died. Seeing a sign of an established breed from the trial of such an ill-assorted pair, I decided upon placing her in another pen and looking out for a better and nearer match; yet although I changed her pen she still was allowed her liberty with the others during the day, but at night her place was with the Toys, and to this abode she soon became accustomed. After each day out with the flyers she would in the evening wait upon the window-frame of her home for me to let her into it. And so things went on for months, until one night, being busily engaged to an unusually late hour, I quite forgot my Capuchin (for such I named her, as in some degree resembling that kind), until I was aroused from my writing by a fall of crockery, and then heard the whirr, whirr, of wings. Up I rose and out I went, directing my steps to the paneless portion of the window, hoping to find the bird still there; but, no! she was gone, whither I knew not, but my suspicions were soon aroused on seeing by the light of the moon a cat, whose tiger-like form I clearly beheld as it scaled a high wall in rather too hasty a manner to look innocent. To the cats, then, my bird has gone thought I, and I retired brooding vengeance on the feline race.

A week or more elapsed, when, as Honorary Secretary of the Birmingham Columbarian Society, I attended our periodical meeting, and ere business commenced the following questions were addressed to me by our President (Mr. H. Allsopp). "Mr. Ludlow, have you lost any of your birds lately?" I replied "Yes, unfortunately, a very good Antwerp cock." "But have you not lost any other?" "Yes, I have," said I, "if a bird can be lost when you know where it is gone," and then I told the members about the crash, the rush upon the foe, the hasty retreat, the shadow-like form in the moonlight, &c. Then our worthy President informed me that his reason for asking the question was that he had caught a bird similar to that which he had seen at my place, and had it then in his pocket. Without further questioning he produced the bird, and there, sure enough, was my poor cat-killed Capuchin, who, no doubt frightened from her snooze on the window-frame by the nightly peregrinations of the tabby, had probably flown some distance by moonlight, and so was lost and captured the next day three miles from my place, which had been her only home in this country. Thus it will be seen that although she has never been out of my possession from the time I took her off shipboard, she had flown from the Secretary's to the President's, and in her course, whether straight or circuitous, over the large industrial hive of Birmingham and Aston, with its 106,470 dwellings, inhabited by 489,313 persons, besides the thickly populated suburbs adjoining. When we also take into consideration the hundreds of Pigeon-keepers in Birmingham, who between the hours of one and two o'clock turn out their immense kits of flyers for their daily airing, it must be considered a remarkable incident that my peculiar foreigner should have passed from my keeping in so strange a manner, and have been captured at the house of my fellow fancier, friend, and colleague, whilst it was stealing its frugal meal in company with a few birds which are set at large, and kept as feeders for his better birds.—J. W. LUDLOW, *Vauxhall Road, Birmingham.*

PARASITES ON CANARIES.

I WOULD supplement the remarks made by Mr. Blakston on this subject (see page 94) by adding that, as I have already pointed out in "The Entomologist," a fruitful and frequently-overlooked source of the very troublesome Acari is the seeds with which the birds are supplied. There are certainly bird-lice which have nothing to do with the seeds, and which, like fleas, breed in the birds; there are others which swarm in the seeds—more at some seasons of the year than at others)—and from these transfer themselves to the birds. I have detected these in canary, rape, and hemp, mostly small; and yet they evidently not only live amongst, but devour the seeds. At the first opportunity, however, they are quite prepared to betake themselves to animal food. These Acari do not appear to trouble the birds during the day, when they cluster together in corners and angles, to await the dusk, which sends them out on their rambles. If the seed-vendors carefully sifted their seed before sending it out, and kept it as dry as possible, there would be a diminution in the number of these Acari, even though it might not be possible to keep the seed entirely free of them.

I do not see what the "worms" could have been to which Mr. Blakston refers, unless, indeed, they were the larvæ of some one of the wood-boring beetles. The bird-lice or Acari, though they undergo some slight changes as they increase in size, do not pass through any transformations. Besides the adoption of the remedial measures already suggested, it has been recommended to apply to all the cracks and crevices in the cages a solution of camphor in spirit of wine and turpentine mixed. The application of train oil to the infected parts of wooden cages has also been very serviceable.—J. R. S. C.

EARLY POLLEN—DYSENTERY.

MY bees carried in pollen on the 2nd of February. The pellets on the thighs were large and yellow. On that day I changed all the floorboards, brushing off numerous dead bees which had perished from dysentery, owing to the very mild damp weather we have had so long. Some of the healthiest stocks were those on which I have had inverted flower pots over the central holes in the top-boards, a piece of perforated zinc intervening. By this plan much of the damp air within the hive seems to be able to make its escape. The floorboards of some hives on which there were no flower pots were very mouldy.—S. BEVAN FOX.

MR. WOODBURY.—The following extract from a notice of the late Mr. Woodbury appeared in the "Bienenzeitung" of October 31st. It well deserves a place in our Journal, and will be read with interest by all who remember his labours in the cause of apiarian science. I am indebted for its translation from the German to one of the daughters of the deceased.—R. S.

"Again, dear bee friends, the sad duty devolves upon me of announcing the death of a man who has done much for apiculture, and who must have been the first best bee-keeper of modern times in England. Indeed, all the readers of the 'Bienenzeitung' remember the name — remember the in-

teresting articles that Woodbury wrote on foreign races of bees, and to translate which was always a pleasant task to me. But the bee-keepers of Germany knew nothing further of the distant friend who first introduced the Italian bee into England, and whose intention of naturalising the Indian bee also was only frustrated by death. One of his last works was the superintendence of the manufacture of a hive in which a swarm (Apis dorsata) should have been introduced into England from India's distant shore, the arrival and success of which was Woodbury's dearest wish."

UNITING SWARMS.

The practice of joining swarms, or what is more commonly termed "chop-offs," to stocks in the autumn is of very old date, and is still recommended in modern works and periodicals. Save by a correspondent to our Journal, who lately recommended the brimstone pit as the best mode of disposing of these surplus bees, and who for his pains got a few stings from some of our worthy bee-masters, I am not aware of the plan ever having been condemned by anyone. Now, although it is universally approved of, I believe the anticipated benefit is seldom derived, for the bees escape dying in spring by meeting with an earlier death when joined to stocks in autumn. I will endeavour briefly to show the advantages and disadvantages of uniting swarms to stocks in autumn, and will then pass on to the proper time at which swarms ought to be joined.

In the first place, let us ask what hives ought to be strengthened in the autumn, and why? Such hives are those only which have aged queens, and whose population has been reduced through the defects of the queen in breeding; or late swarms in a bad season which have lost many bees, and have, therefore, an insufficient population to maintain a uniform degree of heat in winter. It is, therefore, requisite in joining swarms that every precaution should be taken, so that it will be certain that the best queen will be saved and not in any way maimed. From the foregoing it will be seen that it is in few cases that uniting is recommended; in fact, under good management hives do not require to be united in autumn. When bees are joined, if no fighting occur at the time many bee-keepers think all is right, and having so many bees together look forward to securing early swarms next spring. They never think of the mishaps that are almost sure to occur, nor of the natural life of the bee. I may here mention that hives with not less than 3 lbs. of bees, or even 2 lbs., in autumn ought never to be disturbed by uniting, because a healthy queen with that number of subjects will bring forward in spring as many bees as one with double the number; nay, a small second swarm is often the first to swarm. Then why put yourself to all the trouble, and run the risk of having healthy queens destroyed, through uniting where bees are not required? As I have paid particular attention to swarms so joined for many years I will state my observations.

First, when a swarm is joined to a stock both queens are encased, and if not both killed at the time, frequently they do not survive long; and even should one survive, she is often maimed and is seldom allowed to lead a swarm, so that the consequent loss in the spring is far greater than the benefit of a few bees in autumn. Besides, how often are hives really strengthened by this mode? I have seen hives supposed to be peaceably united, have stood beside them after dusk, and seen the bees leaving by the thousand.

This occurs owing to two causes, one being when the bees miss their queen, the other when the one set of bees is assailed by the other; in the former case, the queen of the strange bees being killed immediately after the hives are united. Although the bees themselves have not been meddled with, whenever they miss their queen a commotion commences, almost invariably after daylight, and the bees leave the hive never to return. In the latter case the strange bees, although wounded, are still able to fly, and quit the hive for ever. Thus the unsuspecting bee-keeper is disappointed, and in nine cases out of ten the surviving queen is so maimed that she is often deposed early in the spring, thus causing a cessation of breeding for some weeks; and if not deposed she is seldom able to fly with the swarm, and is sometimes lost. The great danger in uniting bees in autumn can only be obviated in the same manner, and by using the same precautions, as when we join an Italian queen—in fact, it is utterly useless to unite swarms in autumn except in cases where the weight of bees has been reduced to less than 2½ or 3 lbs. A young healthy queen with from 3 to 4 lbs. weight of bees will be far in advance of one with three times that weight made up by joining. "Union is strength," but that strength is only required when there is work to be done. What advantage is there in uniting swarms months before they are required, when it is a well-known fact that in a healthy hive six weeks will be sufficient to supersede every old bee by young ones? It may not be out of place to mention here that I have kept bees until they were fourteen months old. Whenever the apiarian knows he is to have surplus bees he ought to join them in the height of the honey season, and thus make the most of them, disturbing the stocks as little as possible after the honey season is past.

Nor is it requisite to unite swarms for their better keeping in winter, because a hive containing from 3 lbs. and upwards will occupy three or more seams at a temperature of 10°; and this number appears to be quite sufficient, in an unprotected hive with no more than a projecting roof, to stand a cold at several degrees below zero. Such was the case in 1860, when the thermometer sank to 4° below zero. I had a dozen hives standing exposed; the hive itself was only half an inch thick, and the only protection was a ridge projecting 6 inches round the hive. One-half of these hives were not more than half full of combs, and yet they all turned out well in spring. I am not far wrong when I say that a hive three-quarters filled with comb, and one-third of that occupied by bees at a temperature of from 10° to 20°, is about the proportion for a hive to remain healthy and free from disease during winter. A hive filled to overflowing and perfectly full of combs will not winter better than one only three-quarters filled. It is thus necessary to have our hives constructed so that we can add or diminish, not only during winter but throughout the seasons.

Like Mr. Lowe, I do not think it a good plan to divide hives in autumn, yet it is well to have a few nucleuses as described, to be kept in a rather warm and dry place during winter, in order to fill up any wants that may occur in spring through the death of a queen in winter.—A Lanarkshire Bee-keeper.

OUR LETTER BOX.

Age of Stock Game Fowls (*H.*).—We do not believe that birds bred from parents five years old will be as good as those bred from two-year-old birds. Much depends on the condition in which they are when moulting. It is a strain on the system, and, if they are worth a little attention, they should be cared for as much while it is in progress as if they were in training. The quality of the feather will depend much on the material of which it is made.

Weight of Dorkings and Brahmas at Birmingham (*Subscriber*).—Dorking cock, 12 lbs.; hens, 10 lbs. Brahma cock, 13 lbs.; hens, 10 lbs. at the last show.

Poultry Management (*Black Coat*).—Your fowls are better managers for you than you would be for them. The Dorkings are laying now that they may be broody in time to bring you off some early chickens, and the Spanish will be laying all the time the others are sitting. The Spanish are not early layers, but they lay well when they begin, and you will thus be constantly supplied with new eggs. The appearances you describe indicate they will shortly lay, but not that they are laying. You have succeeded, *malgré vous*, in doing that which many try for, and which is the intention of two breeds—viz., to make one succeed the other, and not to have all your eggs at once.

Sowing Grass Seed on Poultry Run (*W. T.*).—You should do it at once so far as the time of year is concerned; but you will, we think, do well to wait till the land does not hold as much wet as it does now. If the extent of the run permit it, shut up half of it at a time. If it does not, keep the poultry out till there are evident signs the seed has taken root and is growing.

Brahma Hens (*W. T.*).—We should hatch our chickens from the eggs laid by the hen without vulture hocks. Nothing would compensate for them. In almost every particular we like the second better than the first. We do not for a moment believe all the chickens (cocks) will have brown patches on the wings. You must weed out those that have. By way of experiment you might set some eggs of the first hen.

Pullets not Laying (*W. H.*).—The cock has nothing to do with laying, but pullets are better satisfied when one runs with them, and we believe they keep in better condition. Borrow one for a week, and that will answer every purpose.

Scurfy Fowls (*Hamburgh*).—We hardly understand the scurvy as applied to the diseases of fowls. There is the white face, which is the disorder from which the Hamburgh is suffering, and the white dry excrescence on the legs. The former is certainly cured by the application of strong sulphur ointment, unless it be the remains of some distant cross with a white-faced breed, as Spanish in Black Hamburghs. In this latter case there is no cure. The excrescence on the legs may be much alleviated by the application of the same made very strong, but it is difficult to cure. The best thing you can do with the hen is to purge her thoroughly with castor oil, and feed her on ground oats slaked with milk, bread soaked in milk, and a small quantity of kitchen scraps chopped fine. When she is recovering you can use Baily's pills advantageously, and as soon as there appears some life in her let her out. While she is confined nothing will be more beneficial than to give her daily a sod of growing grass cut with plenty of mould. If this treatment will not help her, we should advise you either to kill her, or else let her take her chance, unless she lays golden eggs. The best food we know for fowls is ground oats; when these cannot be had, barleymeal. One of these slaked with water should be given for the morning and evening meals. At midday give maize, barley, and kitchen scraps. Where the latter are given the quantity of corn should be diminished.

Poultry House (*Far West*).—We should prefer to make the end of the house, *a*, *a*, solid without a door. We should then make two-thirds of the

lattice-work also solid, save two small glazed windows in the upper part. The remainder of the front may then be lattice-work, with the exception of the end, which would form the door. We return the sketch that you may see our meaning. Your perches would then run from the marks *o*, *o*, *o*, inside the building, and would rest on a ledge opposite to them, fastened to the "side of outhouse." This would afford protection sufficient for any weather, because there would be no draught. The accommodation of numbers of poultry is of little importance as regards roosting, the run during the day is the most important point in that particular. You seem well off for space, and food to be had for foraging, the best food there is for poultry, but they must not quite depend upon it, and they should always have as much food as they will run after given to them early in the morning. You do not mention green food, whether they have access to grass; if not, they must be provided with something of the sort. Refuse vegetables will do. They will also want grit or gravel, and some bricklayer's rubbish thrown down. They should always have the option of going out. Remaining the run is a large one, you may safely keep twenty-four Brahmas and a dozen Bantams. If you wish it we believe you may keep more.

POLANDS FEATHER-EATING (*J. J. C.*).—It is a very rare thing to find fowls eating feathers at this time of year. It is by no means uncommon late in the season when the plumage is old, and the birds are sickly previous to moulting. Your hypothesis is not a correct one. It is supposed to arise from a disorded state of body. Of course they are confined, or they would not do it. Remove the cock and supply the hens with green food, especially with sods of growing grass cut with plenty of mould. It is more than possible they may find in that the change they want, and for which they substitute feathers. Avoid all stimulating food.

FLOOR OF POULTRY-YARD (*Geva*).—A concrete floor or run for poultry is a very bad one. It affords no scratch for the fowls, it is unyielding to the feet, and consequently keeps them always on the stretch. This is uncomfortable for the fowls, and that which is so is detrimental to their condition. We should infinitely prefer the sharp gravel. We are afraid we have more rats than you have, but they do not kill our chickens. They eat their food.

BIRMINGHAM CUP DORKING COCKEREL.—"I find that the year in which I purchased the bird was 1869, inadvertently stated as 1870. Unfortunately my Dorkings are unable to speak for themselves, otherwise they would, doubtless, ask Mr. Waller to state in what respect they 'are incorrect,' and further to point out that their birthplace is 'The Laurels, Taunton,' not 'Birmingham.' —J. B. SAUNDERS."

POISONED FOWLS (*Birmingham*).—Your hypothesis of the labels containing arsenic is not admissible. We have no doubt Mr. Harley's fowls were purposely poisoned. The analysis shows there was arsenic "in considerable quantity." There are too many cases of maiming and disfiguring exhibited fowls for us to doubt that some exhibitors are malicious and revengefully jealous.

CHINESE FOWLS.—"On reading the answer to 'G. C. A.' (page 93), about Chinese fowls, and the letter headed 'Black Cochin-Chinas' (page 90), I was reminded of some fowls which I saw last summer recently imported from Hong Kong, and which were said to be of a valuable breed. These were Black, mostly with dark-reds and beards, some with the peculiar double comb of half-bred Crève-Cœurs; indeed, soyons might have fancied they were Cochins crossed with Crève-Cœurs.—LETITIA WARD, *The Close, Salisbury.*"

INDUCING A HEN TO SIT.—"A hen may be persuaded to sit at any time of the year.—VINCENT FRASER." See page 110. "A SUBSCRIBER" will be greatly obliged by information how this is done. Perhaps "VINCENT FRASER' will reply to this.

BEAK OF MAGPIE PIGEON (*A Reader*).—Magpies certainly should have dark beaks; birds of this variety are not perfect if the colour of beak is otherwise. Many specimens are too often seen with the upper mandible of the beak dark, and the lower one light, which is a decided blemish. The beak should be nearly black, corresponding with the intense black head of the bird.

PIGEONS GOING LIGHT.—"If Mr. H. Allsop will give his Pigeons castor-oil pills instead of castor oil he will not soil the plumage of his birds. A friend of mine has tried them with success.—S. H."

PIGEONS AND CANARIES (*J. W.*).—White Jacobins, although they had bull eyes, yet being, as you say, very good in other points, might win. Match your Evenly-marked Buff cock Canary with a rich Jonque hen, either clear in colour, but having Evenly-marked blood in her, or Evenly-marked if having Crested blood; or being Crested, you would get Evenly-marked and Crested birds as well. Mind the markings are not too heavy. We think that this class of Canary is a good one for amateurs to breed for exhibition, especially to begin with.

SWAN-NECKED EGYPTIAN PIGEONS (*Pharamond*).—We know nothing of this large variety of Scandaroon. Certainly those exhibited recently were by no means large. Mr. Baily, of Mount Street, imports a great number of birds from the Continent, and most likely could procure them for you.

CANARY'S HEAD UNFEATHERED (*Edith*).—If by any accident a Canary should get the top of its head thoroughly plucked, it will most frequently remain bare until the next moult. Such may be the case with the wild Canaries from Madeira, to which you refer. If the baldness arise from what is known as scurf—and the description given seems to indicate it—anoint the part with fresh butter as free from salt as it can be made by washing, and give plenty of green food—watercress, lettuce, a slice of apple, the inner leaf of the heart of a cabbage, chickweed, groundsel—such as can be obtained.—W. A. BLAKSTON.

DEAD CANARY (*J. S. W.*).—The defunct subject is a Buff bird with a cross of Norwich in it. The colour indicates that it might pass for a Norwich bird, but a very poor specimen. You describe him as a "fine straight bird," which "stood up well on his legs." That indicates a strain of what is known as Yorkshire. But judging from his appearance in his coffin, I should say there was as much Norwich as anything in the departed.—W. A. BLAKSTON.

BEES AT CAMBERWELL (*Constant Subscriber*).—We have no doubt they will thrive if well managed. They were kept by Wildman in Holborn.

BEES DYING (*W. J. H.*).—It is probable that your bees have died of dysentery. The extremely damp and mild weather which has prevailed this winter is the cause of great mortality. As you say that you have fed liberally, it is not likely that your bees have perished of starvation. You cannot do better, if the mortality still continues, than to frequently change the floorboard. Spring feeding usually commences in March; but if you have any doubt as to your hive having a sufficient supply of food stored up, you had better give your bees the benefit of the doubt, and let them have a few ounces of food twice a-week on any mild day. We do not reply by post to queries.

REMOVING A HIVE (*T. H.*).—A hive of bees may safely be moved 4 feet from its present position with perfect safety, provided it be done in mild still weather when the sun is shining. Choose the first warm, unclouded day when the bees come out in force. The later you can put off the operation the better, of course, as the sun's rays are acquiring heat every day.

REMARKS.

Jan. 31st.—Fine in morning and throughout the day.

Feb. 1st.—Cloudy in the night, white frost in the morning, fine sunrise, bright till about 3 P.M., then dull, rain between 4 and 5 P.M., and in the evening with wind at night.

2nd.—Rain in the night, fair but overcast in the morning, then showery with bright sun between, sharp shower with hail at 0.34 P.M.

3rd.—Very dark early in morning, but brighter about 2 P.M., dull afternoon, fine evening.

4th.—Dull and showery all day. Red Aurora spreading nearly all over the sky from 6.15 to 6.29 P.M., and again from 8.10 to 8.45. Very bright in S.E. in the early part of the evening.

5th.—Showery, damp, and dull all day.

6th.—Overcast in morning, a little rain about noon, and occasionally through the day, but not enough to measure. Fine night.

A very similar week to its many precursors, southerly winds, high temperature, great moisture, and a generally cloudy sky.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 7.

A STEADY regular business is being done without any marked improvement in the general tone. Supplies of home-grown produce are well kept up, and from the Continent and Channel Islands we have rather more than usual at this season. Broccolis both from Jersey and Cornwall are excellent. Good sound Potatoes of the different varieties command a fair sale. Inferior descriptions are very heavy.

From observations taken near London during forty-three years, the average day temperature of the week is 46.1°; and its night temperature 31.1°. The greatest heat was 59°, on the 16th, 1847; and the lowest cold 3°, on the 17th, 1855. The greatest fall of rain was 0.51 inch.

VINE DISEASE AND VINE STOCKS.

FROM my childhood I have cultivated the Vine, and, having suffered disappointment on more than one occasion, I can sympathise with those who have shared the same fate. Being a lover of the Vine, I wish to direct the attention of your readers to the existence of a widespread disease which is destroying the Grape Vine in this country (the United States), and which I have reason to believe will ultimately prove a source of annoyance and disappointment to the Grape-growers of England.

The subject of the Grape-leaf louse has been exhaustively treated of by Mr. C. V. Riley in the columns of the *Rural New Yorker*, and from his communications I shall freely quote. Mr. Riley refers to the decline of the Grape in this country, and states, "I have at last ascertained the one real and principal cause of this decline, and that knowing the cause, we may in a measure obviate it, will doubtless cause many a Grape-grower to wonder. This destructive agent is none other than a little insect that has long been known in this country by the name of THE GRAPE-LEAF GALL LOUSE (Phylloxera vitifoliæ, *Fitch*).

"I use the specific name first given to the insect by Dr. Fitch, of New York, simply because it is the best known in this country, and suffices for my present purpose. The name itself is perhaps objectionable, and so little was known of the true character of the louse when Dr. Fitch described it, that he did not even refer it to its proper genus. It is doubtful, therefore, whether the accord of the entomological world will be given to this name, notwithstanding its priority, in the place of Phylloxera vastatrix which Planchon first correctly gave to the root-inhabiting form, and which has been generally recognised abroad. The same may be said of Westwood's name Peritymbia vitisana, which was also proposed for the same insect in 1868 in a communication to the Ashmolean Society of Oxford, England.

"The Clinton Vine and its near relatives have long been known in this country to be subject to the attacks of an insect which covers the leaves with galls. No one, however, dreamed that the roots of our Vines were afflicted with a similar insect until last fall, when I showed that the gall louse wintered on the roots. These facts were published in my last report, from which I quote the following paragraph in order to give the recorded history of the insect. It will be seen from these extracts that the first mention of the galls in print was in 1856; but there is good evidence that they were noticed, and even referred to, many years before, without any real knowledge of their character.

"The first reference to this insect was briefly made by Dr. Fitch, of New York, in the year 1856, and he subsequently described it in a very insufficient manner under the name Pemphigus vitifoliæ. Ten years afterwards this louse was again referred to by myself in the *Prairie Farmer* for August 3rd, 1866; and during the fall of the same year articles were written upon it by Dr. Shimer, and by my late associate, Mr. Walsh; the former claiming that it was a true plant louse (Aphis family), and the latter that it was a lark louse (Coccus family). In this Dr. Shimer was evidently right and Mr. Walsh wrong. In January, 1867, Dr. Shimer proposed for this insect a new family, Dactylœsperidæ, which in my opinion cannot stand.

"During all this time a serious disease of the roots of the Grape Vine began to attract attention in the south of France, and it finally caused such alarm that the Minister of Agriculture and Commerce in France offered a prize of 20,000 francs for the discovery of an efficacious and practical remedy. In France the disease is known as Pourredie, or rotting. It is in the form of little cancerous spots, which cut off the supply of nourishment, and cause the roots to rot; and these spots were ascertained by MM. Planchon and Lichtenstein, of Montpellier, to be caused by a louse (Phylloxera vastatrix, *Planchon*) which bears a close resemblance to our gall louse. This is not all, for a leaf-gall, absolutely identical with ours, also occurs there, and the identity of the gall-inhabiting with the root-inhabiting insect was demonstrated by 'I. O. W.' in the *Gardeners' Chronicle* (of England) for January 30th, 1869; and M. J. Lichtenstein even contended that the European species was identical with ours, and imported from this country, in which opinion he was supported by A. Combe.

"In the latitude of St. Louis, Missouri, the first galls are noticed about the middle of May, and by the middle of June they begin to be quite common. The galls vary somewhat in appearance according to the Vine upon which they occur. The few individuals which start the race early in the year station themselves upon the upper sides of the leaves, and by constant suction and irritation soon cause the leaf to swell irregularly on the opposite side, while the upper part of the leaf gradually becomes fuzzy and close, so that the louse at last sinks from view, and is snugly settled in her gall. Her bulk increases during pregnancy. Eventually she grows to be plump and swollen, acquires a deep yellow or orange tint, and crowds the space within the gall with her small yellow eggs, numbering from fifty to four or five hundred, according to the size of the gall. The young lice are pale yellow. As soon as they are hatched they escape from the gall through the orifice in the upper surface of the leaf, which was never entirely closed, and taking up their abode on the young and tender leaves, in their turn form galls. The mother louse, after completing her deposit, dies, and the gall which she occupied dries up. There are several generations during the year, and this process goes on as long as the Vines put forth fresh leaves. As the galls multiply, and the growth of the Vine becomes less vigorous, the young lice sometimes so completely cover the upper surface of the newly-expanded leaves as not to leave room for them all to form galls. In this event the leaf soon perishes, and the lice perish with it. Those leaves which have been badly attacked turn brown or black, and sooner or later fall to the ground, so that the Vine may be entirely denuded.

"By August the insects become so prodigiously multi-

plied that they often settle on the tendrils, leafstalks, and tender branches, where they form excrescences and gall-like growths, differing only from those on the leaves in such manner as one would naturally expect from the difference in the plant tissues. After the Vine has finished its growth, the young lice, finding no more succulent and suitable leaves, begin to wander and seek the roots; so that by the end of September the galls are deserted.

"The young hatched from the eggs on the roots are absolutely indistinguishable from those hatched in the galls; and the gravid apterous female differs in no respect whatever from the mother gall louse. The females on the roots seem to be less prolific than those on the gall, and their eggs, if anything, are rather larger. These eggs are always of a bright yellow, and on the dark root are detected with the naked eye as readily as the lice, which become darker, or a dull orange, as they grow older.

"The insect is found on the roots in all stages during the summer months. In the winter it is found dormant, principally in the larva state, and no eggs are to be seen. With the circulation of the sap in the spring the activity of these young recommences, and in a short time afterwards eggs are deposited again. At this season the punctures of their little beaks produce very decided swellings, and an excess of moisture at the wounded parts. The winged forms are by no means uncommon, and commence to issue from the ground perhaps as early as July."

Mr. Riley examined a large number of Vines in and distant from St. Louis, and I shall merely quote the result as regards a few. "Vitis vinifera (European). All European varieties with roots badly affected. In many instances decomposed and gone, with the Vines about dead. No leaf-galls. Concord (native variety), no leaf-galls, scarcely any root-lice. Almost entirely exempt." From the researches of Mr. Riley a large number of our native varieties suffer to a great extent; but as it would not interest your readers, I shall not occupy space by quoting the results of his researches, but merely refer to the fact that, in accordance with his experience, the Concord probably suffers less from the Vine louse than any other variety.

For a lengthened period it had been a well-recognised fact that European Grapes would not succeed in this country under ordinary garden culture. Grapes being a marketable fruit, a number of persons endeavoured to supply the national want by the raising of seedlings, some purely native, and others hybrids between native and European varieties. Hundreds of varieties were raised and disseminated; but experience established the fact that only a limited number remained healthy and luxuriant in any soil and situation.—Al Fresco, *New Jersey, U.S.*

(To be continued.)

THE ROYAL HORTICULTURAL SOCIETY.

ANNUAL GENERAL MEETING.

FEBRUARY 13TH.

The Annual General Meeting of the Royal Horticultural Society was held last Tuesday afternoon in the Council-room, South Kensington. In the unavoidable absence of Lord Henry G. Lennox, M.P., the chair was taken by G. F. Wilson, Esq., F.R.S.

The Chairman said he had received a letter from Lord Henry Lennox, M.P., who was expected to have presided at the meeting, stating that important matters had prevented him doing so.

Mr. Richards, the Assistant Secretary, read the Minutes of the last annual meeting, which were confirmed.

Messrs. Fortune and Moore were appointed Scrutineers for the ballot.

The Assistant Secretary then read the Annual Report, which we append.

The Chairman said that was the time for any Fellow who had a remark to make upon the Report to do so. He might observe that the accounts were annexed to the Report and had been circulated with it.

Mr. Blenkins said it afforded him much pleasure to move that the very satisfactory Report which they had just heard read should be received and adopted by the meeting. He thought he should have the concurrence of all the Fellows present when he said the Report was a really satisfactory one [hear, hear]. Last year, when he had the honour of seconding the adoption of the Annual Report, he took occasion to remark that he entertained a firm belief that a union between the Exhibition Commissioners and the Council of the Royal Horticultural Society would be highly beneficial to the latter. The highly satisfactory Report which had been presented to them that day showed he was right when he anticipated this improvement. He hoped this union would long continue, and that they should receive from it not alone their present advantages, but the still further privileges which the continuance of exhibitions must ensure [hear, hear]. With these few remarks, he had much pleasure in moving that the Report be received and adopted.

Professor Tennant said he should, in seconding the motion for the adoption of the Report, make one or two suggestions which might be found useful. It was well known that the Society gave to their members tickets which admitted persons to the gardens on certain days of the week; but unfortunately these tickets were not available on Sunday, the very day when many people could most conveniently visit them [hear, hear]; the day to which many a one would look forward during the week for a pleasant day in the gardens. What was refused in this Society was conceded in others. In the Zoological Society, for instance, the system of issuing tickets of admission for Sunday worked with a marked success; and in that Society the plan existed of giving to members tickets to admit two persons on Sundays. The Horticultural Society should, he thought, take this matter into consideration; and he was confident, if they did adopt the plan referred to, the Society would be a considerable gainer by it. The plan which worked best was to give tickets regularly dated, so that no member could give more than two admissions for any one day. Formerly, in the Zoological Society, the members were very liberal in getting and giving tickets, but not in paying their subscriptions [a laugh]. That had been obviated now by not giving tickets to any member who had not paid up his subscription [hear, hear]. He begged to second the motion.

Mr. Wooster said he must take exception to the expense set down in the accounts for the tents, which certainly were the greatest eyesores the Council had ever had to put up with. He presumed the Council had sanctioned the construction of what was a remarkably handsome tent, and which it was a pity had been destroyed. Now, there was a tent erected at the lower part of the garden, which would have been a disgrace fifty years ago [hear, hear]. He felt it was a shame these tents cost so much. One thing he was very pleased at, and that was that the Council had decided upon the appointment of a Botanical Professor, who by lectures, answers to personal inquiries, and other means, should assist in establishing a more correct knowledge of the principles of botany and horticulture. That he looked upon as a step in the right direction [hear, hear]. It was a great advantage to be able to have one's questions answered, and he had known many instances in which Fellows had not been able to obtain the information on botanical and horticultural subjects which they sought, and which was so essential to those whose tastes lay in that direction [hear, hear]. The action of the Council in this respect could not fail to prove highly beneficial to the Society.

Mr. Godson said he should preface the few remarks he was about to make by proposing, of course as a suggestion to be considered by the meeting, that his Royal Highness Prince Arthur, whose name stood on the balloting list for the Council, should be elected by acclamation, as was usual in the case of members of the Royal Family [cheers]. He was glad his suggestion had met with the approval of the meeting, as he had felt certain it would. Coming now to the statement of accounts, he found in the capital account an item of £700 disallowed by the Expenses Committee. Now, he hoped some reason would be given why that £700 had been disallowed. He was sorry to disturb the harmony with which the Report had been received, but he thought it right to say he did not think they should be playing fast and loose in the way they were. Looking at the way in which the election of the Council was managed, he could not help bringing under the notice of the meeting, that one year they had a gentleman voted out, and the next year they had him voted in. This year, for instance, they had one man voted out, and another voted in. Now, with all deference, he thought that looked too much like a family compact. He thought all the Fellows ought to have a chance of being placed upon the Council, because it was an honour now in a peculiarly marked degree to be on the Council, as Royalty belonged to it [hear, hear]. In the Report Mr. E. J. Lowe was applauded and praised for what he did for the Society last year, and what was the gratitude shown him? Why he was sent out of the Council this year [hear, and a laugh]. Looking at the circumstances under which Mr. Lowe was praised in the Report, seeing that the Council say with respect to the Show at Nottingham, that—"Besides having produced a Show of unusual beauty and interest, they realised a net profit of £774, a result which the Council feel to be in a great measure due to the devoted and untiring labours of one of their number, Mr. E. J. Lowe," he thought that gentleman ought to have been kept on the Council, and he believed the meeting would be of the same opinion. There was another point which he had no doubt the Secretary would explain. How was it, he should like to know, they were charged £2400 for rent to Her Majesty's Commissioners of 1851 in respect to the gardens, and yet no income tax was allowed? Now, £50 or £60 was, he thought, a matter worthy of considera-

tion. He did not like making these remarks, but he could not help doing so when he read in the Report this passage :—"The Fellows will find that notwithstanding the reduction of the establishment at Chiswick, its expenses have last year risen from £1335 8s. 7d. to £2060 19s. 11d. The explanation of this is the large drafts made on the garden at Chiswick by the establishment at South Kensington, rendered necessary by the International Exhibition." Now, that had never been admitted before. He thought his Grace the Duke of Devonshire was entitled to their thanks for the manner in which he had acted with respect to the Chiswick property [hear, hear]. Another observation he wished to make was with reference to the fact, that while people paid 1s. 6d. each to go into the Exhibition, those who went round by the Gardens the same day and hour had to pay 2s. 6d. He hoped that state of things was or would be corrected [hear, hear], and he felt satisfied if the £2400 rent paid to Her Majesty's Commissioners of 1851, and other payments and monies were taken into account, it would be found that the Society was not under those great obligations to the Commissioners which it was probably thought they were. When they found that only £388 13s. had been given for the rent of the two arcades, the meeting would have the whole case of the Exhibition before them; and he could only say he thought the Commissioners might act more liberally than they did [hear, hear]. He hoped a fair explanation would be given on the points to which he had called attention. It was as a matter of justice, which was due to the other Fellows who had not an opportunity of criticising the Report, that his observations had been made; and he hoped, if they had any weight with the Council, that the subject matter of them would be gone into as soon as possible [hear, hear].

The Chairman, replying to the remarks of the several speakers, said his friend who seconded the adoption of the Report suggested that greater facilities as to the acquisition of tickets to the gardens should be given. That was a matter entirely for the Fellows themselves [hear]. Of course the great object the Council, and, indeed, all connected with the Society, had in view, was to keep the gardens as quiet as possible on Sundays [hear, hear]. Increased facilities for admission would, of course, bring more people to visit the gardens than might be altogether agreeable [hear]. He should put it to the meeting whether they would vote for or against this suggestion for increased facilities for admission to the gardens.

Mr. Godson.—You must have a special meeting for that purpose.

Professor Tennant.—At present it is merely a suggestion thrown out, and not a direct motion.

A Fellow.—The Botanic Society, at the Regent's Park, entertained a similar suggestion without calling a special meeting.

The Chairman said the question was really one which involved that of increased privileges. Mr. Wooster had spoken of the loss of the large tent, but he might remark it had one disadvantage —it was like a white elephant, very expensive—and it was on ground which the Society had to give up at six months' notice. Mr. Godson suggested that His Royal Highness Prince Arthur should be elected on the Council by acclamation, and he (the Chairman) had much pleasure in putting that motion to the meeting.

Mr. Godson seconded the motion, which was carried amid cheers.

The Chairman observed that Mr. Godson had made some remarks as to Mr. Lowe being removed from the Council. That was a matter which did not, by any means, rest with the Council. A bye-law existed which provided that two members of the Council should go out every year by reason of non-attendance, the object being to keep new blood in the Council. Mr. Lowe, on the present occasion, was one of those who went out for non-attendance, and only on account of non-attendance. Mr. Godson also spoke of the £2400 rent paid the Commissioners, without deduction of income tax. In reply to that observation he might say £2400 was the sum fixed for rent without the question of income tax being at all entertained.

Mr. Godson.—The Act of Parliament makes it imperative that the income tax should be allowed, and I am surprised that the Treasurer does not know that as well as his A B C [laughter].

The Chairman.—This £2400 was paid for rent, but will you please remember we owe five or six years' rent which we have not paid? [hear, hear.]

The motion for the adoption of the Report was then put and carried unanimously.

Mr. Richards (Assistant Secretary) said the votes were unanimous in favour of the election of the officers named by the Council, and with respect to the new Councilmen, there was one dissentient. The following is the list of officers elected:—President, His Grace the Duke of Buccleuch, K.G.; Treasurer, Mr. John Clutton; Secretary, Major-General H. Y. D. Scott, C.B.; Expenses Committeemen, Mr. John Clutton, Mr. W. Wilson Saunders, F.R.S.; Mr. Sigismund Rücker, F.L.S. Auditors, Mr. James Nicholson, Mr. John Gibson, Mr. Robert Hudson, F.R.S. The names of vacating members of Council were Major R. Trevor Clarke, Rev. Joshua Dix (deceased), Mr. E. J. Lowe, F.R.S. The names of Fellows recommended by the Council to fill the above-mentioned ordinary vacancies were H.R.H. the Prince Arthur, Mr. Arthur Grote, F.L.S., and Mr. Andrew Murray, F.L.S.

Mr. Fernyhough said he had heard many complaints respecting the annoyance caused by children at the musical promenades, and by the fact that the servant girls took for themselves the very best places to be had [hear, hear]. Perambulators and hoops were undoubtedly a nuisance when music was being played, and probably the Council might adopt some remedy for it.

Mr. Wooster suggested that terra cotta medallions of the most eminent botanists should be placed in the niches of the arcades. On the capitals, too, he should suggest that floricultural groups should be placed—a suggestion which had been carried out at Oxford.

General Scott thought it would be a mistake to put the busts of distinguished botanists on the walls referred to. He had heard various opinions as to the Oxford capitals, but there was an old saying, "Beggars must not be choosers." The Society had not paid for the capitals, and it would be difficult to get sculptors equal to the task proposed. It should be remembered that the Commissioners had gone to the expense of making all the improvements round the gardens; and that they were not done by the Society at all. There was plenty of space for busts, even busts of full size.

The Chairman said, with reference to the remarks of Mr. Fernyhough, the Council would do the best they could to reduce or abate the annoyance complained of, but it would be a difficult position to be placed between the Council and the mothers [laughter].

General Scott had considerable sympathy in this subject with the fathers and mothers of the children, for he had a large family himself; but he should think a change, having for its object that there should be only one child admitted per ticket instead of two, would meet the difficulty. That was a subject on which he thought the meeting should express an opinion, because it was upon matters like these the Council wanted their hands strengthened [hear, hear]. Then as to the Sunday admissions, the Council would try to do what they could; and upon this question also the meeting ought to express its opinion.

Mr. Blenkins believed they were all delighted to see the children in the gardens when they were well-behaved; but he thought that on show days, or music-promenade days, certain instructions ought to be given to the attendants to have the annoyance caused by the children abated [hear, hear]. At the same time, there could be no doubt that there could be no better place in which to have the tastes of children cultivated than in these gardens [hear, hear].

A Fellow asked whether the trellis division in the gardens was about to be removed, as many of the Fellows very much objected to it, because they could not get to that part of the gardens without running the gauntlet of the weather.

The Chairman said it was not intended to remove the trellis-work.

After a vote of thanks to the Chairman the proceedings came to a close.

Report of the Council to the Annual General Meeting.

1. The Council, in their last year's Report, expressed a confident expectation that the International Exhibition, then about to be opened under the direction of Her Majesty's Commissioners, would tend greatly to the advantage of the Society. Their anticipation has been fully realised, and they have the gratification of announcing to the Fellows that the Society has participated largely in its success. Not only has it profited by the Exhibition being made accessible to them and their families on especially favourable terms, but the result of the arrangement entered into with the Commissioners (by which, in consideration of the temporary use of the Arcades and other facilities given by the Society, it should receive a payment by way of a royalty of 1d. for every visitor to the Exhibition), has been to place to their credit a sum of £5030 0s. 11d.

2. It was not to be expected, nor did the Council ever anticipate, that so important an operation could be carried through, and so large an increase to their income for the year be acquired, without some reduction of certain sources of income on which the Society had been accustomed to rely. The amount of such reduction, however, has been small, as will be seen by a comparison of the different items of receipt and expenditure in last year's statement of accounts, with that which accompanies this Report.

3. On turning to the side showing the receipts, it will be found that the sum received this year for annual subscriptions shows no material difference; the amount received this year being £7115 17s., as against £7177 last year. The number of Fellows continues nearly the same. The items where the receipts have

fallen, and where the fall may be directly traced to the Exhibition, are the daily admissions and promenades, the rent of space in the arcades, and the produce of Exhibitions and Fêtes. The sum received for daily admissions and promenades has fallen from £463 6*s.* 9*d.* to £172 4*s.* 1*d.*; the rent of space in the arcades, from £424 to £388 18*s.*; and the produce of Exhibitions and Fêtes, from £9277 7*s.* to £634 6*s.* 1*d.* A considerable diminution in the receipts for garden produce was of course to be looked for after the garden at Chiswick had been so much reduced in size, at all events until the new arrangements are in working order. It has, however, proved much less than the Council anticipated —viz., from £578 5*s.* 11*d.* to £349 15*s.* 4*d.* The alterations at Chiswick have been completed, and the new walls built, the expenses having partly been borne by the adjoining tenant and partly defrayed from the sale of plants and other produce in the ground given up.

4. The Council have the pleasure to announce that although in the year 1870 the Society sustained a slight loss from the Show at Oxford, this last year they more than redeemed it at Nottingham. Besides having produced a Show of unusual beauty and interest, they realised a net profit of £774, a result which the Council feel to be in a great measure due to the devoted and untiring labours of one of their number, Mr. E. J. Lowe.

5. Turning to the other side of the account, the Fellows will find, that notwithstanding the reduction of the establishment at Chiswick, its expenses have last year risen from £1335 8*s.* 7*d.* to £2060 19*s.* 11*d.* The explanation of this is the large drafts made on the garden at Chiswick by the establishment at South Kensington, rendered necessary by the International Exhibition.

6. On South Kensington Garden the expenses have also been considerably increased, the amount this year being £3802 2*s.* 6*d.* instead of £2359 10*s.* 7*d.* The expenses of Exhibitions last year were £1484 7*s.* 7*d.*, this year they amounted to £1916 8*s.* 4*d.* This increase must be regarded as part of the necessary outlay required to produce the receipt of £5030 11*s.* from the Exhibition.

7. It is also to be observed that the amount of Kensington Garden expenses is largely increased by the payment of £500 to Mr. Foley for his exquisite piece of sculpture, "The Boy at the Stream," which was produced under arrangements initiated by H.R.H. the Prince Consort, at the establishment of the garden at South Kensington in 1861, and which has remained unexecuted until now. The work, though ordered in 1862, was delivered only in 1870.

8. Another large item which the Fellows will observe in the expenditure is £500 paid on account of tents. This is the first instalment of a payment of £1400, which those two fine tents now in the gardens will cost. These tents had become essential to the continued success of the Society's Shows.

9. The foregoing is a brief summary of the working business of the past year. It now remains to say a few words in anticipation of that of the coming year. The Council have only two alterations of any moment in view, but both are important. Many Fellows who were in town during the period of the Exhibition, and who availed themselves of their privileges, may have felt some degree of inconvenience from the arrangements with the Exhibition Commissioners as to entrance into the Exhibition and gardens, and all of them must have agreed that it would have been a very great boon had their Fellows' tickets admitted them to the Exhibition on the same footing that they did to the gardens. Feeling this, the Council have endeavoured to make arrangements with the Commissioners, by which this privilege should be acquired, and they have the satisfaction of announcing to the Fellows that the Commissioners have agreed to grant the privilege sought by the Council for the present year, in consideration of the use of the Quadrant Arcades by visitors to the Exhibition.

10. The other step is the appointment of a Botanical Professor, who, by lectures, answers to personal inquiries, and other means, shall assist in establishing a more correct knowledge of the principles of botany and horticulture, and of the names of plants, among those of the Fellows and their gardeners who are desirous to profit by the opportunity. An abstract of the duties proposed to be attached to the position is annexed, and the Council believe that they have secured a very competent botanist and horticulturist to undertake them, in the person of Mr. Thistleton Dyer, late Professor of Botany in the University of Dublin.

Duties of the Professor of Botany.

1.—General. — To conduct the scientific business of the Society, both horticultural and botanical. To enter into communication with horticultural and botanical establishments at home and abroad, and especially with the Societies in union with the Royal Horticultural Society.

2.—South Kensington.—To attend the meetings and exhibitions of the Society, and there note carefully, and report upon all objects of merit, for publication by the Society; also to pay attention to the correct naming of the plants exhibited.

To aid the Rev. M. J. Berkeley at the Wednesday meetings.

To be at the offices one afternoon in each week, for the purpose of answering any scientific inquiries which may be made by the Fellows.

To edit any publications which the Society may issue.

To give a series of lectures on subjects connected with scientific horticulture to the Fellows and others during the session, as the Council may direct.

To take charge of the library and look to its increase.

3.—Chiswick.—To take care that all plants of botanical interest be properly named.

To inspect all scientific experiments made in the garden, to report the results, and offer suggestions for further experiments relative to scientific horticulture and the growth of plants.

To be present one afternoon each week to give information on such points as may be necessary to Fellows and gardeners of Fellows, and to receive from them plants which may require botanical names.

To give a series of lectures each year to the students in the gardens and the gardeners of Fellows on scientific horticulture and botany.

To report monthly on the meteorological observations made in the garden.

To form one of the Horticultural Board of Directors.

Extracts from the Reports of the Horticultural Directors.

Scientific Committee.—Under the peculiar circumstances of the gardens at Chiswick in 1871, it was impossible for the Board of Direction to do more than apply all their energies to the best mode of carrying out the necessary alterations. In consequence of the lateness of the season at which anything effectual could be accomplished, there was considerable anxiety as to the fate of the valuable stock, which could not be removed till a period far later than was desirable. It is, however, with great pleasure that they are able to report that the removal of the trees was most successful. Partly from constant care, and partly from a very favourable condition of weather, not a single plant of any value failed, and the gardens must now be considered as in a most satisfactory condition. The Board will now be prepared to carry out any horticultural experiments which may be suggested, while it is hoped that, under the regulations proposed by the Council for Lectures to Students, the gardens may become a very valuable school for horticulture. The Board cannot help congratulating the Society in having been able to retain the services of Mr. Barron, which could not possibly have been very well replaced.

Pomological Department.—What has chiefly occupied attention in the pomological department during the past year has been the preparation and furnishing of the ground, in the new arrangement of the garden, with the fruit trees that were removed from the old orchard. The advantages of this reconstruction are now apparent, and not the least important of these is the classifying of the trees, by which facilities are obtained for comparing and judging of the different varieties. The Board take this opportunity of testifying to the skill displayed by Mr. Barron in the way the new arrangements have been carried out and completed. Although the whole of the open space appropriated to the fruit department has been completed, the new boundary walls have yet to be furnished. Steps have been taken, and are now in progress, to obtain such trees as are adapted for that purpose, and ere spring has much advanced as complete a collection of Apricots, Cherries, Peaches, and Nectarines, as it is possible to obtain shall have been secured, and the former high reputation of the Chiswick garden for its pomological collections will have been restored. Up to the present time there exist, under the successful re-arrangement of these, about 400 sorts of Apples, 350 of Pears, 300 of Plums, 430 of Cherries, 220 of Vines, and 100 of Figs. Of the last there are yet many varieties that have not been determined.

Besides the work of reconstruction, an extensive experimental trial of the numerous varieties of Borecole or Kale has been made, by which the confusion so much complained of will be cleared up, and the various names by which the varieties are known will be referred to their proper places. This season arrangements have been made for a trial of Peas, of which the varieties have become so numerous, and the confusion of names so complicated, since the last great trial in the garden.

In the Great Vinery there is a very marked improvement in the condition of the Vines since the enlargement and re-dressing of the border, and the heading-down of some of the varieties. The new Grape, Madresfield Court, which was at first supposed to be a variety requiring hot treatment, has proved to be one of the very best for a cool house, equalling if not surpassing the Black Hamburgh in the high condition it attains under such circumstances. A Vine of this variety was planted in company with one of the Black Hamburgh in the Rev. Mr. Fountaine's vinery, which was erected in the garden, and although the house has no provision of any kind for being artificially heated, the Madresfield Court Grape ripened thoroughly, and was considered to be much better adapted for such a situation than the Black Hamburgh.

As usual, the Fellows have made good use of the privilege afforded them in obtaining scions of fruit trees and seeds from

the garden. During the past year the distribution of each has been as follows :—

60,000 packets of vegetable seeds.
4,500 packets of cuttings of Figs, Vines, and other fruit trees.
600 plants of Figs distributed by ballot.

Floral Department.—Owing to the alterations which have been in progress at Chiswick, but little opportunity was afforded during the season of 1871 for carrying on the usual trial of flowers. These alterations have included the formation, in the vicinity of the Council Room, of a new series of beds for the growth of Trial Plants; and though it was late in the season before these beds were completed, a collection of Bedding Pelargoniums was nevertheless got together, and planted ont in time to make satisfactory progress. These were examined in the month of August by the Floral Committee, when the following awards were made :—

First-Class Certificates.—*As Flowering Plants:* Lawrence Heywood, Charley Casbon, Mrs. Mellows, Lady Kirkland, Stanstead Rival, R. Bowley, Waltham Seedling, Louis Veuillot, Penelope. *As Foliage Plants:* Goldfinder, Macbeth, Louisa Smith, Black Douglas.

Second-Class Certificates.—*As Flowering Plants:* Demosthenes, Arthur Pearson, Murillo, Triomphe de Stella, Augustine Rongier, The Champion, Mrs. Menzies, Mdlle. Nillson, Cleopatra, Acme, Madame Lemoine. *As Foliage Plants:* Miss Batters, Florence.

In the present season it is proposed to continue the trials of bedding Pelargoniums, and to add in the out-door department collections of Pentstemons and Phloxes, and in the in-door department of Fuchsias—all of which have been much augmented as to the number of varieties, and materially improved as regards quality, since the former examinations of them were made.

On the wall bounding the trial ground on the west, it is proposed to grow examples of Ornamental Hardy Climbers, instead of fruit trees as heretofore. Contributions for this object will be acceptable. Notwithstanding the reduction of space in the garden, the collection of Herbaceous Perennials which had been recently acquired, has been retained, and any further accessions thereto, or to the class of Hardy Bulbs, especially Lilies, would be welcomed.

The Chiswick garden has contributed, during the past year, to the garden at Kensington, the following supplies—viz., For the decoration of the Conservatory about 20,000 plants; and for other purposes of furnishing and decoration, about 50,000 plants.

The distributions made to the Fellows during the year, in this department, have comprised 7000 useful plants, allotted by ballot, and 60,000 packets of flower-seeds.

FRUIT AND FLORAL MEETING.

February 14th.

Last year the meeting held just one day later proved one of the best the Society ever had so early in the season, but this year the floral display was even better, the room being filled with numbers of choice Orchids, splendid masses of Chinese Primulas and Cyclamens, and such a diversity of other plants, that the whole formed, in fact, an exhibition of no small extent.

Fruit Committee.—George F. Wilson, Esq., in the chair. Reference was made to the recent sudden death of the late Mr. Thomas Osborn, a member of this Committee, and it was unanimously resolved to recommend to the Council that a letter of condolence be sent to Mrs. Osborn testifying to the valuable services rendered to the Committee by her husband.

Mr. James Allan, gardener to Lord Denbigh, Newnham Paddox, sent specimens of a Sprouting Kale, which the Committee considered a spurious form of Brussels Sprouts, and not superior to other varieties of Sprouting Kale already in cultivation. Mr. William Melville, of the Royal Vinery, St. Lawrence, Jersey, sent a collection of coloured Kales, some of which are proliferous on the midribs of the leaves; the latter are very beautiful, and received a cultural commendation.

Mr. Dixon, gardener to Lady Holland, Holland Park, Kensington, sent dishes of Beurré de Rance, Glou Morçeau, and Easter Beurré. All three were in excellent condition, and the flavour, especially Easter Beurré and Glou Morçeau, was unusually good.

Mr. Gilbert, gardener to the Marquis of Exeter, Burghley, sent the model of a box for preserving Grapes in a fresh state during exhibition, by means of water-bottles and a glass protection. The Committee approved the general principle, but decline to give an opinion upon the model till it has been put into practice.

Prizes were offered for the best three dishes of Dessert Apples, also for the best three dishes of Dessert Pears. In the former Mr. G. T. Miles, gardener to Lord Carrington, was first with Blenheim Pippin, Ribston Pippin, and King of the Pippins; and Mr. Parsons, gardener to R. Attenborough, Esq., Acton Green, second with the last two and Braddick's Nonpareil. For Pears the first prize was awarded to Mr. Stephenson, gardener to F. Barker, Esq., Leigh Hill, Essex, who had Winter Nelis, Glou Morçeau, and Passe Colmar. Mr. Gardner, gardener to Colonel Astley, Elsham Hall, Brigg, was second.

Floral Committee.—Dr. Denny in the chair. From Messrs. Veitch came a grand collection of Orchids, consisting of Lycaste Skinneri literally masses of flower, Dendrobium Hillii with three large spikes of pale yellow blossoms, a number of specimens of Odontoglossum crispum or Alexandræ beautifully coloured; Oncidium fuscatum, conspicuous by its purple-marked lip; the deli-

ciously-scented white-and-yellow-flowered Pilumna fragrans; Odontoglossum tripudians from New Grenada, a magnificent specimen of Cœlogyne cristata, quite a mass of white and yellow flowers; Lycaste Skinneri alba, a beautiful milk-white variety, with just a little yellow in the throat; Ada aurantiaca, Cypripediums, including the lively-coloured C. Schlimii, several Odontoglossums, Cypripedium vexillarium, and many others. Along with these were Hippeastrum Leopoldii and pardinum, both very showy, and the latter a very fine specimen. Messrs. Veitch also sent a collection of Palms, of which Kentia australis and Veitchia canterburyana, two very handsome species, both from Lord Howe's Island, had first-class certificates. The Veitchia in particular is likely to form a beautiful object for table decoration, the young leaves being of a lively green.

Mr. Ware, Hale Farm Nurseries, Tottenham, sent a basket of spring-flowering plants, in which Hepaticas of different kinds and Iris reticulata were the most conspicuous. Mr. Croucher, gardener to J. T. Peacock, Esq., Hammersmith, sent Agave Morganii, a Mexican species, also Agave Gibbsii from Brazil. Mr. C. Noble, Sunningdale Nursery, sent Thujopsis borealis aureo-variegata, with well-marked yellow variegation. This received a first-class certificate.

Mr. W. Paul exhibited several plants of his fine white Chinese Primula, Waltham White. From Mr. R. Clark, market gardener, Twickenham, came a beautiful collection of Cyclamens; and other collections in fine bloom came from Mr. Wiggins, gardener to W. Beck, Esq., Isleworth; Mr. James, gardener to W. F. Watson, Esq., Isleworth; and Mr. Goddard, gardener to H. Little, Esq., Twickenham, those from the latter being in many instances splendid masses of white, rose, and rosy purple blossom, while several were beautifully spotted.

Mr. Ware, Tottenham, sent a fine basket of Iris reticulata, and from the same exhibitor came a collection of Succulents.

Messrs. Rollisson, Tooting, contributed a fine miscellaneous group of Orchids, Palms, and stove and greenhouse plants. From Mr. Williams, Holloway, came Vanda suavis, Cœlogyne cristata in excellent bloom, and Angræcum eburneum. Mr. Denning, gardener to Lord Londesborough, Grimston Park, Tadcaster, sent in a splendid collection of Orchids a magnificent pan of Lælia anceps in which there were eighteen spikes of flower, some with as many as four blossoms, also beautiful specimens of Cœlogyne cristata, Odontoglossum Alexandræ, and Phalænopsis grandiflora, together with Odontoglossum nebulosum and Cattleyas.

From Mr. B. Johnson, gardener to T. Clarke, Esq., Swakeleys, Uxbridge, came a remarkably fine specimen of Daphne indica rubra, balloon-trained, and bearing a profusion of flowers. Messrs. Standish & Co., Ascot, sent a large collection of forced flowers, as Bouvardias, Hyacinths, Spiræa japonica, Geraniums, and Cinerarias. Among the last-named were several remarkable for their newness and intensity of colour. Mr. Howard, gardener to J. Brand, Esq., Balham, contributed pans of Lily of the Valley, exceedingly well grown, and a very choice bouquet.

Mr. Wilson, gardener to W. Marshall, Esq., Enfield, sent two plants of Masdevallia ignea, one with four, the other with seven scapes, but these were not all fully developed. The four, however, were beautiful. Two boxes of beautiful cut blooms of Camellias were exhibited by Mr. William Paul, of Waltham Cross, and collections were likewise shown by Mr. Grant, gardener to J. B. Glegg, Esq., Withington Hall, Cheshire, and Mr. Howard, Balham.

From Mr. Speed, gardener to the Duke of Devonshire, Chatsworth, came a beautiful raceme of Amherstia nobilis, a tree which has several times flowered there before, and of which a full account will be found in vol. x., page 240. Mr. Richards, gardener to Baron Rothschild, Gunnersbury, sent Odontoglossum Alexandræ with very large flowers. Messrs. Carter & Co. exhibited Prince of Wales, Princess Royal, and other Caladiums; and Mr. Bull, Odontoglossum odoratum, yellow, spotted with brown, but so far as we could make out scentless, or nearly so, also Masdevallia ignea, poor compared to the specimens from Mr. Wilson. Mr. Williams, of Holloway, exhibited Davallia Tyermanni, a pretty dark green graceful Fern; Tillandsia Lindeni major, with beautiful deep blue flowers; Odontoglossum tripudians oculatum, and a group of hybrid Solanums. From Mr. Green, gardener to W. Wilson Saunders, Esq., came Rhipidodendron plicatile majus, a South African succulent plant, somewhat resembling a lady's fan. Mr. D. Ferguson, Hounslow, exhibited propagating-glasses, consisting of a flat piece of glass fixed in a circular rim of sheet iron. It appears to us that a piece of glass placed over the pot would answer equally well, and be less expensive. Mr. Matthews, Weston-super-Mare, sent Gibson's Orchid pots, with perforated sides and false bottoms, said to be much superior to the ordinary perforated pots.

Two prizes were offered for the best six Chinese Primulas, distinct; the first was taken by Mr. Goddard, gardener to H. Little, Esq., Twickenham, who had really distinct and rich-coloured varieties, also very well flowered. No second prize was awarded, but an extra was given to Messrs. Dobson, of Isleworth, who, along with Messrs. James and Tomkins, had plants in excellent bloom.

Mr. William Paul, Waltham Cross, offered three liberal prizes for three plants of his Waltham White Primula, but there was only one exhibitor—namely, Mr. J. Scott, gardener to J. B. Howitt, Esq., Enfield, who took a first prize.

The best three plants of Dielytra spectabilis were exhibited by Mr. George, gardener to Miss Nicholson, Putney Heath; Mr. Denning coming in second with larger plants but not so well bloomed.

The only collection of six Lycastes was that shown by Mr. Denning; it contained one splendid specimen of Lycaste Skinneri, others fine, and one plant of the white kind.

First-class certificates were awarded to Messrs. Veitch for Kentia australis and Veitchia canterburyana; to Mr. Williams for Davallia Tyermanni; to Mr. C. Noble for Thujopsis borealis aureo-variegata; to Mr. Green, gardener to W. Wilson Saunders, Esq., for Rhipidodendron plicatile majus; and to Mr. Croucher for Agave Morganii and A. Gibbsii. Mr. Bull had a second-class certificate for Odontoglossum odoratum. Cultural commendations were given to Mr. Tomkins for Chinese Primulas; to Mr. Speed for Amherstia nobilis; to Mr. Grant and Mr. W. Paul for cut Camellias; to Mr. Johnson for Daphne indica rubra; to Mr. Richards for Odontoglossum Alexandræ; to Messrs. Veitch for their group of Orchids, also for Hippeastrum pardinum; to Messrs. Rollisson for a group of Orchids, &c.; to Mr. Williams for Orchids; to Mr. Denning for Pilumna fragrans, also for a collection of Orchids; to Mr. Wilson for Masdevallia ignea; to Mr. Laurence, gardener to Bishop Sumner, for Dendrochilum glumaceum; to Mr. Wiggins for Cyclamens; to Mr. Ware for a group of Succulents; to Messrs. Standish for a large group of plants; and to Mr. Howard, Balham, for Lily of the Valley and a bouquet.

Dissolving Bones.—"W. H. W.," *Reading, Mass.*, in the "Horticulturist," says:—"My mode of doing this is very simple and very effective. I have a large water-tight hogshead standing out-doors, near the kitchen. In the spring I cover the bottom about 6 inches deep with dry soil. On this I put a layer of bones of about the same depth, and cover them entirely with unleached ashes; on these another layer of bones, then ashes, and so on till the hogshead is full. I leave it then exposed to the rains all summer and winter until the next spring. Then, on removing the contents of the hogshead, I find nearly all the bones so soft that they will crumble to powder under a very slight pressure, and, mixed with the ashes and the soil, they give me a nice little pile of most valuable manure, ready for immediate use. Any of the bones not sufficiently subdued I return to the hogshead again for another twelvemonth's slumber."

PALMS FOR COOL CULTURE.

The following Palms will succeed in a temperature which does not fall below 38° or 40°, and are, therefore, peculiarly adapted for the decoration of apartments. It must, however, be borne in mind that small one-year-old plants should not be placed in so low a temperature, as they are not effective at that age, and grow very slowly under such treatment. It is preferable, therefore, to procure plants from three years old and upwards for this purpose. There are many other kinds which will succeed, but, on the whole, none of them are more satisfactory than those mentioned below. They require plenty of water during summer, but less in the winter, never being allowed to grow dry. A little liquid manure in spring is very beneficial, and is not offensive if some of the various patent kinds be used.

It is quite a pleasure to see the rapid progress Palms are making in the estimation of the public for general decorative purposes. The appearance they present to anyone seeing them in a room for the first time is perfectly enchanting. As a warning, however, let all amateurs avoid Geonomas, which—though as beautiful, dwarf, ornamental plants in a stove they are certainly unsurpassed—unlike the Chamædoreas, look miserable in the drawing-room, and become unpresentable after a week's trial—in fact, rapidly die.

Acanthorhiza stauracantha.—A native of Mexico; leaves palmate or fan-shaped, divided into broad segments quite down to the ligule or top of the petiole, dark green on the upper side, silvery white below.

Areca lutescens.—A beautiful species with graceful arching leaves, divided into narrow dark green segments; the footstalks are orange yellow freckled with black dots.

Chamædorea graminifolia.—This is certainly the most elegant of its genus, almost rivalling the much-prized Cocos

Weddeliana, and, indeed, proving to the amateur a superior plant, as it does not require stove heat like the Cocos. Stem slender; leaves pinnate, segments long and narrow, beautifully arched, and dark green, resembling a plume of ostrich feathers.

Chamædorea Wendlandi.—The best of the genus for room decoration, as I have abundantly proved; leaves pinnate, segments broad and bright shining green.

Chamærops excelsa.—Leaves deep green, fan-like, divided round the margin into narrow segments.

Chamærops humilis.—The only European species of this extensive and noble order. Leaves fan-shaped, divided into narrow segments about a third of their entire length, glaucous; footstalks armed at the edges with stout spines.

Livistonia australis.—Robust grower, exceedingly handsome; leaves nearly round, much plaited, and divided round the edges into narrow segments, rich deep green; footstalks dark brown, armed at the edges with stout sharp spines. A native of New South Wales.

Livistonia borbonica.—Leaves fan-shaped, divided at the margins into pendulous and bright shining green segments; footstalks armed with stout spines.

Malortiea simplex.—Stem slender; leaves entire, fringed at the margins, and deep green in colour; they are supported upon short very slender footstalks. It is a native of Costa Rica.

Kentia Baueri, from Norfolk Island, is a very beautiful unarmed Palm. Leaves pinnate and plume-like, with broad and rich green segments.

Seaforthia elegans of our gardens is a free-growing noble plant, with pinnate light green leaves, with long and broad segments. It is more correctly named Ptychosperma Cunninghami.

Phœnix dactylifera, the Date Palm of commerce (of which an illustration was given nine weeks back), with dark green pinnate leaves; very distinct and very hardy.—Experto Crede.

IRON FOR ROSES.

I read with great interest a late communication on this subject. I did not, on reflection, attribute the growth of the Rose to any manurial or tonic influence of the iron rust. The summer was very rainy, and the ground was much chilled. It is probable that the iron shielded the roots from the rain, and then when the sun came out the iron became heated and influenced the roots. Your correspondent would do well to try this season on two Roses of the same kind, in the same situation, and treated alike, two slabs of iron—the one painted on both sides, and the other in its rusty form. He may then be able to draw a conclusion. I know of only one plant that really likes iron in the soil—namely, the British Queen Strawberry. I should think that if iron abounded in soils it would be injurious to plants generally. Still, plants in the same family have likes and dislikes.

Much mischief was done last summer to Roses by fungoid disease. I never knew orange fungus so prevalent. The roots, moreover, were much injured by long-continued cold rains. The Roses here of all kinds look well. Soon after Christmas I cut away much damaged wood and useless spray, and shortened the remaining branches. I have three very successful specimens of Maréchal Niel whip-grafted on the Manetti stock, also one on the Briar, and one budded on the Gloire de Dijon. The Cloth of Gold would oftener succeed if people were to put an iron plate or stone slab over the roots.—W. F. Radclyffe.

A FEW RELIABLE ADDITIONS TO THE FLOWER GARDEN.

Amongst the first of these I ought to name Dracænas grandis, Cooperi, and terminalis, which cannot, of course, be reckoned novelties, as they are well known, and have already been classed among the more tender kinds of subtropical plants; but the Dracæna is a far more enduring plant when planted out of doors than many who are only acquainted with it as a stove plant would credit.

I have already drawn attention to it in this respect, and last summer's experience enables me to speak with more confidence about it. About midsummer I put out some two dozen Dracænas along with other fine-foliaged plants, and they kept their foliage intact till October. Japanese Maize, in the same group, was blown to ribbons, and had to be replaced with Acer Negundo variegatum in pots. Those who think of using the Dracæna this season should encourage the growth of plants that were struck last spring, and which ought to be 2 feet high by the time they are wanted. A fortnight or so before they are planted out the plants should be removed from the stove, and hardened-off in the greenhouse or in cold Peach houses: here we put them out in their pots, and then they are easily taken up on an emergency.

Kleinia repens.—This is one of the few succulents that will associate as a dwarf edging to ordinary bedding plants. Its short fleshy leaves are densely covered with a fine blue bloom, of a light and very pleasing shade, that will be found exceedingly useful as an intermediate colour. It is a dwarf-growing plant, and should be planted thickly. Cuttings will strike at any season of the year if afforded a temperature ranging from 55° to 65°, and kept moderately dry. It is about the easiest plant to propagate that I know. I began with about a dozen plants last spring, and shall have three or four thousand by bedding-out time, and could have had more if needful. The bloom on the leaves will resist heavy rains.

Pachyphyton bracteatum (Succulent). — This is another beautiful little plant, forming a very neat, dwarf rosette, with leaves of a rich cream colour. It does not take so kindly to the society of ordinary bedding plants as the Kleinia, but it makes an extremely pleasing foreground to the latter, and in this way the contrast may be toned down very well. Unfortunately it is difficult to propagate; though we began with a better stock than we had of the Kleinia, we shall not have hundreds of the one for thousands of the other. The Pachyphyton is best propagated by seed, if it can be got, and by leaves, which should be taken off carefully, and laid in rows on the surface of the soil in a pan or pot, and otherwise treated the same as the Kleinia. Each leaf, if carefully managed, will put forth a crowd of little ones at the base.

Variegated Lemon Thyme.—This is another good plant, in every respect like the common Lemon Thyme, quite as hardy, and free-growing. The leaves are of a bright yellow colour round the edges, and the same tinge extends to nearly two-thirds of the surface of the leaf. It is certain to become popular as a dwarf edging plant; and as it retains its variegation throughout the winter, it will be very useful for the winter garden also.—J. Simpson, *Wortley Hall Gardens*.

SOLANUM MACRANTHUM.

Some of my readers may think an alliance with the Potato is no recommendation to the ornamental properties of this plant; but a glance at the illustration of it (which we owe to M. Alphand's "Promenades de Paris") will, I think, cause them to form a different opinion of the cousins of the Potato. The genus Solanum is a very widely distributed one, but the headquarters of the family is certainly in South America. The genus includes a great variety of types, some being mere low-growing annuals, others shrubs, whilst some attain to the dimensions of small trees. Some species are used medicinally, but by far the most useful one to man is S. tuberosum, a plant now well known by everyone as the Potato, which, like the subject of our engraving, originally came from South America.

Amongst the various species of Solanum which grow to the size of shrubs are some with large bold leaves, which afford quite a distinct feature in a group of plants, and have been pressed into the service of the gardener from their suitableness for the summer decoration of gardens. Their bold leaves, in many instances ornamented with stout spines of various colours, make them very attractive, and as it is bold, distinct features that are required in such situations, we hope both gardeners and amateurs will look upon the Solanum family with more favour than is usually accorded them. The species now under consideration, S. macranthum, is a very handsome plant, a native of Brazil. The stem is woolly and prickly; the leaves large, sub-cordate, acuminate, angularly-lobed, and clothed on both sides with a stellate tomentum, which is greyish green above and dull red below; the nerves are red, but the primary ones are furnished with stout spines of a yellowish brown colour. The whole plant forms a charming object for general purposes of decoration, and when seen in good condition it cannot fail to please even the most fastidious. The flowers are also large and conspicuous, but as the foliage is its principal attraction, little need be said here respecting its inflorescence.

I wish to say, in passing, that I think a great mistake is made by many, both gardeners and amateurs, in objecting to

call a garden, formed by the association of tropical plants with the denizens of temperate climes, sub-tropical. Complaints are frequently made against gardeners and amateurs about their management of the large-leaved sub-tropical plants, and which can easily be explained. Most people who use these plants treat them to a somewhat warm house during winter, and then gradually inure them to the open air by a process of hardening-off. This I look upon as a wrong system. I prefer keeping such plants as cool as possible during winter, so as to prevent them making any growth until after they are placed out of doors. By this means the foliage which is made in the open air will be more hardy, and always look superior to that which exists only by sufferance. I am convinced that this treatment will lead the gardener or amateur to success, and I hope my readers will give the results of their efforts in this direction. I do not say that it is possible thus to prevent the plants making some growth before they are put out of doors, nor to allow the amateur to use any kind of plant, but it will materially assist in making this subject more attractive, and the expense less in carrying it ont.

As an illustration of my meaning, I will suppose that I have purchased some three or four dozen plants, such as Palms, Aralias, some of the Solanums, &c., which I use in my flower garden, but when winter comes I have no stove to place them in, and it may be, under the ordinary circumstances, no greenhouse: I must either destroy them or pay some one for taking care of them through the winter. If, however, I knew that the majority, or, perhaps, all of them, would make beautiful objects for the decoration of my hall, my drawing-room, and various other places about my house during winter, and then be in a better condition than my neighbours' plants in spring, because they had not been excited into growth prematurely, would I not use them so? I think it is a great inducement even to those who have no glass structures, to surround themselves with some bold and effective plants, to mix with showy-flowered neighbours in the beds and borders.

Solanum macranthum.

I must conclude these remarks, however, by once more referring to S. macranthum, which may be increased either by seeds or cuttings, and should be grown in light rich soil of loam, peat, leaf mould, and sand in about equal parts. In potting, the drainage should be good, and the water plentiful when the plants are in an active state. When dormant, or directly after pruning, very little water should be given until indications of growth become visible.—Experto Crede.

REVIEW.

The Forest Trees of Britain. By the Rev. C. A. Johns, F.L.S., &c. London: Society for Promoting Christian Knowledge.

Three circumstances are essential to the production of a good book—namely, a good subject, a good writer, and a good publisher. The volume before us benefited by those three circumstances. The forest trees of our country are intimately connected with its history and its welfare. Mr. Johns is a most suitable writer on such a subject—he has a general knowledge of natural history, he is a fluent writer, and his family grouped around him are thoroughly congenial. We should like to raise the curtain and exhibit the wife pen in hand, and the daughter with the pencil illustrating her friend's song, "Wait a little, laddie." Such family surroundings are needful to the man who writes genially on such subjects. It is only on dry mathematics that an old bachelor can write; or a Socrates on abstract philosophy, having a scolding wife.

Then a few words relative to the Society, publishers of this volume. During the year just closed it issued 178,828 Bibles; 77,690 New Testaments; 400,698 Common Prayers, and nearly three millions of other bound books, of which that before us was one. These were not all sold, but many thousands of pounds worth were given away. In addition, the Society granted from its funds £5791 for building churches and schools at home and in the Colonies. The Society's total outlay for those and cognate purposes amounted to more than £25,000. We mention these facts because we know that the Society has been generous to an excess, and is fully entitled to increased support. We therefore commend it earnestly to our readers as deserving their aid.

Let us now recur to the volume before us, and we will select for extract the description of the Birch. We thought that we were thoroughly acquainted with its uses, for the acquaintance commenced painfully in early life, but Mr. Johns has gathered together much that is new to us.

"No tree is more generally or more deservedly admired on the ground of its own intrinsic beauty than the Birch. As the

Oak has no tree to vie with itself in the sterner attributes of majesty, dignity, and strength, so the

'most beautiful
Of forest trees, the Lady of the Woods,'

stands unrivalled in lightness, grace, and elegance. In one respect it even claims precedence over the monarch of the forest, and that one which its slender and delicate form would least lead us to expect: it stands in need of no protection from other trees in any stage of its growth, and loves the bleak mountain-side and other exposed situations, from which the sturdy Oak shrinks with dismay. But the style of beauty in which each of these trees excels is so widely different in kind, that neither of them can properly interfere with the other.

Leaf and flower of the Birch.

"Pliny describes the Birch as a slender tree inhabiting the cold parts of Gaul. The branches, he says, were used for making baskets and the hoops of casks; and the fasces, or bundles of rods which were carried before the Roman magistrates, were made of Birch twigs; the use, therefore, of the weapon which, in modern times, is the terror of idle schoolboys, is of high classical authority. Branches of this tree were formerly used for decking the houses in Rogation week, as Holly is at Christmas. Gerard says the branches 'serve well to the decking-up of houses and banquetting-rooms for places of pleasure, and beautifying the streetes in the Cross, or gang, weeke' (the same as Rogation week), 'and such like.'

"The Birch is a native of the colder regions of Europe and Asia. Throughout the whole of the Russian empire it is more common than any other tree, being found in every wood and grove from the Baltic Sea to the Eastern Ocean, and frequently occupying the forest to the exclusion of almost every other tree. It grows from Mount Etna to Iceland; in the warmer countries being found at a high elevation in the mountains, and varying in character according to the temperature. In Italy, where it grows, though it appears from Pliny's account not to have been noticed by the ancients, it forms little woods at an elevation of 6000 feet; on some of the Highland mountains it is found at the height of 3500 feet. In Greenland it is the only tree; but wherever it grows it diminishes in size according to the decreased temperature to which it is exposed.

The Weeping Birch.

"The peculiar characteristics of the Birch are, as it has been remarked, lightness and elegance, qualities which are owing to the slenderness of the main stem in proportion to its height, the wiriness of the branches, and the thinness and small size of the foliage. It is equally remarkable for the colouring of its bark, which is marked with brown, yellow, and silvery touches, which are very picturesque, contrasting well with the dark green hue of the leaves. The younger twigs have no such variety of colour, being of a uniform purple brown. The leaves are sharp-pointed, stalked, and unevenly serrated. In April and May the flowers appear in the form of drooping catkins, some of which produce stamens only and drop off early. The fertile ones bear very small winged nuts, and fall to pieces when ripe, scattering the numerous seeds. The barren catkins are formed in summer, but do not expand till the fertile catkins appear in the following spring. A kind of resin exudes from the leaves and young twigs, which is highly fragrant, especially after rain or heavy dew. This resin appears to have been collected in Pliny's time; as he speaks of a bitumen which the tree produces. The odour arising from it is very perceptible to a person passing near a tree, and affords another reason why the Birch should be planted near houses.

"A variety of the Birch is often met with in the Highlands which differs from the common species, by having the shoots pendulous. This is a yet more elegant tree than the first described, and is frequently planted in parks and gardens. It possesses another advantage in being of quicker growth and attaining a larger size. There is also a slight difference in the leaves, which are smaller and somewhat downy.

"The Birch is a tree of rapid growth, especially when young; and as it is little affected by exposure, it forms an excellent nurse for other trees. The soil which it prefers is turf over sand, and in such situations it attains maturity in about fifty years; but it seldom exceeds 50 feet in height, with a trunk from 12 to 18 inches in diameter. The bark possesses the singular property of being more durable than the wood which it encircles. Of this the peasants of Sweden and Lapland, where Birch is very abundant, take advantage, and, shaping it like tiles, cover their houses with it. Travellers in Lapland have noticed in the Birch-forests, that when the soil is very scanty, the trees are liable to be blown down; so that, in some places, as many are seen lying on the ground as are left standing. Such as have lain long are found to have entirely lost the substance of the wood, the bark remaining a hollow cylinder without any symptom of decay. In North America this durability of the bark is turned to good account in the structure of canoes. The Canadians select a tree with a large and smooth trunk. In the spring, two circular incisions are made quite through the bark, several feet from each other. Two vertical incisions are then made on opposite sides of the tree; after which a wooden wedge is introduced, by which the bark is easily detached in plates usually 10 or 12 feet long, and 2 feet 9 inches broad. To form the canoe, they are stitched together with the fibrous roots of the White Spruce. The seams are coated with resin from the Balm of Gilead. Great use is made of these canoes by the savages and by the French Canadians in their long journeys into the interior of the country: they are very light, and are easily carried on the shoulders from one lake or river to another. A canoe calculated for four persons weighs from 40 to 50 lbs. Some of them are made to carry fifteen passengers. This species is known as the Paper Birch.

"The thin white bark of the common Birch, which peels off like paper, is highly inflammable, and will burn like a candle. The Birch abounds in a sweet watery sap, which was formerly much valued for its supposed medicinal virtues. The method pursued in collecting it is as follows:—About the beginning of March an oblique cut is made, almost as deep as the pith, under some wide-spreading branch, into which a small stone or chip is inserted, to keep the lips of the wound open. To this orifice a bottle is attached to collect the flowing juice, which is clear, watery, and sweetish, but retains something both of the taste and odour of the tree. Various receipts are given for the pre-

paration of the wine. That recommended by Evelyn can hardly fail to produce an agreeable beverage. He directs that it should be boiled for an hour, with a quart of honey to every gallon of juice, a few cloves, some lemon-peel, and a small proportion of cinnamon and mace. It should then be fermented with yeast, and bottled. This process, according to the same author, does not injure the tree, for he mentions having observed a Birch which was so treated for very many years, and nevertheless grew to an unusual size.

"The wood of the Birch is white shaded with red, and, if grown in a very cold climate, lasts a long while. It is used for packing-cases, turnery, wooden shoes, and the felloes of wheels, but is inferior to other kinds of timber for all these purposes. A piece of Birch wood was once found in Siberia, changed entirely into stone, while the cuticle, or outer coating of the bark, of a satiny whiteness, was exactly in its natural state, perfectly well-preserved. This proves what was before said of the durability of the bark. Thin pieces of the cuticle are sometimes placed between the soles of shoes, and are found to resist wet. The bark is even wrapped round the lower end of posts which are inserted in the ground, to prevent the moisture from penetrating them. The bark of large trees is used by the Laplanders as a kind of cloak, a hole being made in the centre to admit the head. From smaller trees, about the size of a man's leg, they make boots by removing the wood and leaving a seamless tube of bark. In seasons of scarcity the inner bark is sometimes ground with corn and made into bread; but this, we must hope, happens but rarely.

"From the leaves a yellow dye may be prepared. The wood makes excellent charcoal for gunpowder and crayons; and in northern countries, other parts of the tree are applied to various uses, not, indeed, from any particular fitness of the Birch, but from the absence of trees of any other kind. 'The Highlanders of Scotland make everything of it; they build their houses, make their beds, chairs, tables, dishes, and spoons; construct their mills; make their carts, ploughs, harrows, gates, and fences, and even manufacture ropes of it. The branches are employed as fuel in the distillation of whisky; the spray is used for smoking hams and herrings, for which last purpose it is preferred to every other kind of wood. The bark is used for tanning leather, and sometimes, when dried and twisted into a rope, instead of candles. The spray is used for thatching houses: and, dried in summer, with the leaves on, makes a good bed where Heath is scarce.'—(*London.*)

"In Russia an oil is extracted from the Birch, which is used in the preparation of Russian leather. For this purpose, the white bark, taken either from recent trees or from the decayed trees which are found in the woods, is gathered into a heap, and pressed into a pit shaped like a funnel; it is then set on fire, and covered with turf.

"The oil which trickles down the sides drops into a vessel placed to receive it, and is then stowed away in casks. The purest oil swims at the top, and when used for anointing leather not only imparts a fragrant odour, but makes it durable. Owing to the presence of this oil, books bound in Russian leather are not liable to become mouldy; they also prevent mouldiness in books bound in other leather which happen to be near them.

"The Birch is liable to a disease which shows itself by producing on the upper branches large tufts of twigs, which seen at a distance resemble crows' nests. How it originates is unknown, some persons assigning it to the puncture of an insect, others to peculiarity in the soil.

"A district species of Birch, Betula nana, Dwarf Birch, is found in Scotland and in all the northern countries of continental Europe and America. It is a low wiry shrub, rarely exceeding 3 feet in height, with numerous round notched leaves, which are beautifully veined. By the Laplander it is applied to the same purpose as the twigs of the larger kind."

ROSES AND THEIR NOMENCLATURE.

I see that a discussion has arisen as to the correctness of the term Hybrid Perpetual, and the advisability of changing it. It would seem that no one denies that the name is not scientifically exact. Nearly every garden flower is a hybrid, so that part of the designation is not distinctive, while no Rose is perpetual, strictly speaking. But, on the other hand, we have flowers called "everlasting," that will only last a long time, and every day names equally inconsistent are on our tongue. To remedy this would demand a reform of our entire vocabulary, to be rejected in ten or twenty years when our knowledge would be extended beyond what we should look on then as our ignorance of 1872. The French have a very good word for these Roses, but unfortunately we have no equivalent, while as for adopting the word bodily as it stands, it is not expedient, nor is it any argument to the contrary to say we have already adopted several French words into the language. So much the worse for the language, and for the ears of those conversant with French, other than that of "Stratford-atte Bowe," so often tortured by such words as "amachower" (*amateur*), "trussou" (*trousseau*), and similar barbarities. The nearest approach to Remontant as used for Roses, would be, perhaps, "Reflorescent" or "Ever-bloom." "Cut-and-come-again" might suit, were it not rather disrespectful to the queen of flowers. A similar objection applies to a Greek compound "poly" something or other. The French have more than one word to express this; their perpetual Strawberries they call *Fraises des Quatres Saisons*, or of the four seasons; but their perpetual Carnations are *Œillets rémontants*.

I think, then, the best plan is to strive to improve the flowers, and let the names alone; at least, until we reach the goal of perfection, and coming to a stand-still be enabled to make a final reform in everything without fear of further cause for change. My only regret is, that I have none of these Roses, to trouble me with their names or to delight me with their beauty. My garden is very small, it contains Cabbage Roses, giving a supply of blooms for one month in the year. There is no room for both, and fearing lest the Perpetuals should fail I am mindful of the old adage that tells us to keep the dirty water till we have made sure of the clean.—Far West.

STRAWBERRY CULTURE.

The Strawberry is one of the most easily cultivated and desirable of fruits, and yet, though it is so valuable and wholesome that even the invalid may partake of it freely, not half the attention is bestowed on its culture which its merits deserve, nor so much as is often paid to a crop of spring Cabbages. How often do we find old worn-out beds occupy the same ground year after year, producing only a poor crop of miserable fruit, which does not half pay for the ground the plants occupy. This state of matters is in many cases owing to ignorance of the requirements of the plant, and sometimes also it results from people fancying that the beds require to be planted for a year or two before they come into full bearing. I will, therefore, state as concisely as possible the method which I have found succeed best, both for culture in pots and out of doors.

There is one thing of considerable importance, a knowledge of which can only be obtained by experience, and that is to be able to tell which are the best sorts to cultivate in particular soils and situations. Practical experience is always the most useful; I will, therefore, state mine. Some years previous to my taking my present situation the garden had been totally neglected, the Strawberry beds were in a bad plight, and I found two sorts only were grown; one of them proved to be Black Prince, the other a large late variety of little value, which was soon discarded. The kitchen garden ground is very light and stony on a gravel bottom, and has very little holding power. My employer told me that the ground was not adapted for growing Strawberries, and the old gardener held a similar opinion. However, I meant to try, and selected the most suitable piece of ground in the garden for the base of operations. The first effort was to trench the ground 2 feet deep. This afforded me an excellent opportunity for adding plenty of manure, and a quantity of stiff loam which was procured at considerable cost, but in such soil as I had to deal with the loam was an absolute necessity. I planted the ground with Keens' Seedling, Sir Harry, Rivers's Eliza, Duc de Malakoff, and Prolific Hautbois. They succeeded tolerably well, but did not come up to my expectations. Sir Harry was the only variety retained when the bed was destroyed. Keens' Seedling is so generally good that I am again trying it; from the appearance of the leaves the variety I now have is distinct from that I obtained from the nursery. In unsuitable soils like that which I have to deal with, the only way to obtain satisfactory results is by planting frequently. I destroy the beds after the second crop is gathered.

Many persons are not aware that the best crop of Strawberries is obtained the first season after planting. Good strong runners must be selected, layered in small pots about the middle of July, and planted out in well-prepared ground the first week in August. This will allow the plants to be well established, and the crowns to be matured before winter.

With a few exceptions 2 feet from plant to plant is the best distance. Stir the ground frequently between the rows to keep down weeds, but never dig between them as is sometimes done. All runners should be pinched off as fast as they appear, for they injure the plants if allowed to remain. Of course, a sufficient number of those that are formed when the flower-

trusses are thrown up should be retained for plants. When the fruit is set it is a good practice to mulch between the rows with rotted manure. If the weather is dry a good watering is beneficial, and this mulching serves to retain moisture.

The best method of preserving the ripe fruit from damage is an important consideration. I have seen the mowings from the lawn used to place between the rows; this is a bad material—clean straw is the best, and in dry weather it is very efficient. In wet weather it is very tiresome to have the best fruit eaten by slugs; the only way to prevent this is to keep the fruit in a hanging position, which is easily managed by using small branches of Elm, Beech, or Hornbeam, sticking in a few close to the plants and letting the fruit hang over from the clefts of the sprays. I tried some of the galvanised Strawberry protectors last year, but I prefer the branchlets about a foot long.

I may also make a few remarks on pot culture. There are few gardens where this is not carried on to a greater or less extent. The principal object to be studied in pot culture, is to have the crowns well matured, so that the largest possible per-centage of plants may throw up flower-trusses. In very early forcing it is annoying to have 50 per cent. of the plants unfruitful, and such an occurrence is unfortunately by no means uncommon. When the plants are required for forcing very early, 5-inch pots are the best size in which to fruit the plants, and these should be in the fruiting-pots by the first week of August. For later forcing 6-inch pots are the best. The compost required is very simple—turfy loam five parts, and rotted manure one part; and if convenient it should be laid up a few months previous to use. I generally layer the runners in 60-sized pots; these average 2½ inches in diameter, inside measure. This allows a good space round the balls when repotting into 5 and 6-inch pots. The compost should be rammed in quite firmly with a wooden rammer.

With regard to sorts, much has been written about the capabilities of this and that variety, but it is utterly impossible to say which is the best to plant on certain soils without trial. The only way by which anyone can ascertain which is the best variety for his garden is by planting, say, a dozen of the most approved sorts, and selecting those most suitable for the soil and situation. British Queen I now place at the head of the list as the best variety, both for pot culture and planting out in the garden; it is not the heaviest cropper, but the fruit is large, even in size, and surpassingly good in flavour. Of La Constante I do not think so highly as formerly, but it is very distinct, of neat and compact habit, and bears large crops of equal-sized fruit. Lucas is now preferred to it as being rather better in flavour; the fruit is larger and finer in appearance. President, a variety of sterling merit, does equally well in pots and planted out. Premier we grow for its cropping capabilities, and the fine appearance of the fruit; it is only of medium flavour. Frogmore Late Pine is the best late sort I have yet tried, a good cropper, good in flavour, and even-sized. Amongst new varieties Bradley's "The Amateur," is, I believe, the best, but I shall not be able to thoroughly prove it until next year. 1871 was the worst year in my experience for Strawberries out of doors, but this new variety of Mr. Bradley's was the best I had the opportunity of tasting.

Can any of our contributors or readers say anything of the new continental varieties? I have tried some of them; they are tolerably good, but not good enough to displace our own approved sorts. I see that both Mr. Gilbert and Mr. Radclyffe think very highly of Dr. Hogg. It was splendid with me at first, but it has degenerated, and even young plants die off as if diseased; perhaps a new stock would be an effectual remedy. Galande mentioned by Mr. Radclyffe, and Black Bess spoken highly of by Mr. Gilbert, I know nothing at all about. I can quite understand the secret of Mr. Radclyffe's success, when he states that his runners were planted July 7th. Such plants will carry immense crops next season.—J. Douglas.

KING OF THE MARROWS PEA.

In your number of the 25th ult. the Rev. W. F. Radclyffe mentions King of the Marrows Pea as "large and of admirable flavour." I quite agree with that, for it is quite worthy of such comment, and he says he believes it grows 5 or 6 feet in height. Last summer I had two rows 15 yards long. When they were 4 feet in height I planted a row of Celery between each, thinking they would shade it just long enough for the Celery to hold its own; but imagine my chagrin when, instead of coming into crop, up the Peas went, and still up. I put in a pole 10 feet long at each end of the row, and one in the centre, then stretched strings along each side, and when the Peas produced they were 9 feet 6 inches in height! Of course, owing to their having to stand so long the Celery was considerably drawn, and being rather short I had to use a step ladder in gathering, for the haulm did not bear nearer the ground than 4 feet. The Peas, however, were much praised, being large, bright green, and of fine flavour. There was an immense crop. The soil was stiff, but had been trenched and manured in the previous autumn at both spits; but the Peas looked magnificently, and were wonders.—James Lock, *Surrey*.

GLEICHENIA RUPESTRIS.

Fully agreeing with "T. B." as regards the great beauty of this, to my mind the queen of its tribe, I certainly come to a different conclusion as to why so few amateurs exhibit it. I say, and I think without fear of contradiction, that it is simply because of its great rarity we so seldom see it exhibited by either nurserymen or amateurs. In not one catalogue, and I possess all the principal ones, can I find it, though G. speluncæ, flabellata, dichotoma, dicarpa, and semivestita are quoted in many of them. I only know of three specimens—Mr. Mendel's, Mr. Baines's, and my own. I have just been to measure mine. It is 2 feet 7 inches high, and not quite 4 feet in diameter. I grow my plant in the cooler Fern stove, and "T. B." is quite right that too much heat is injurious to all the members of this lovely tribe. My specimen has fairly started its new growth, and I daresay many of your readers will see it exhibited during the coming season.

The great difficulty with Gleichenias is propagating them. Division is dangerous, and often fatal, while fructification is, with me at any rate, unknown. I am aware that seedlings have been raised, for Mr. Bull's traveller informed me only yesterday that Mr. Bull had been successful in raising some upon one occasion.

Let me conclude by making a remark about Adiantum farleyense. I possess four plants of it, one a very fine specimen 4 feet in diameter, yet I have never seen a fertile frond, and Mr. Williams, of Holloway, when calling upon me a few weeks ago, said that his experience was the same. I cannot help thinking that "T. B." is the possessor of one of the three specimens of G. rupestris known to me.—T. M. Shuttleworth, *Golden Hill, Leyland, near Preston*.

DESTROYING PREDATORY INSECTS.

At page 109, "An Old Subscriber" asks your advice for scale upon orchard-house trees, and I feel much surprised you do not recommend my insect-destroying compound, it being such an easy and effectual cure. If gardeners would give their trees two good syringings as a winter dressing they would not be troubled with scale or any other insect.

My first grand experiment with it upon Peach trees was when the fruit were colouring, and at that time my trees were so infested that the fruit were being discoloured with the secretion from the scale, and I was in fear of losing the whole of the crop. However, I ventured to give them a regular good syringing with my compound, and to my great surprise it not only killed the scale, but cleansed the fruit, and next morning the foliage looked as green and healthy as possible. I used it as hot as I could bear my finger in it, and at the rate of 2 ozs. to the gallon; but for a winter dressing I now use 3 ozs. to the gallon. I syringe all the woodwork as well. I now use it as a winter dressing to my Vines in the same way. —T. C. Clarke.

VALE ROYAL,

The Seat of Lord Delamere.

This mansion is in the deep valley along which passes the river Weever, near Northwich in Cheshire—a valley in part so well clothed with trees as, in the olden time, to be designated "The Monks' Wood," and partly so fertile as to be then called "The Holy Vale of Corn." This is recorded in the register of the abbey subsequently founded there; and the same register states that King Edward I. willed that its old titles should be abolished, and that it be named *Vallem Regalem*, "which in English is King's Dale." He so named it when, in 1277, he laid the foundation stone of an abbey in fulfilment of a vow he made if the Virgin preserved him from shipwreck, imminent as he returned from the Holy Land. That abbey, he it told in

exoneration of modern-architect dilatoriness, was not completed until 1330, and at a cost of £32,000, a vast sum in those days when Wheat, if the harvest was abundant, sold for eighty-pence per quarter. It was tenanted by Cistercian or White monks; and although it is not compatible with the subjects of this Journal to detail all their evil doings, yet a brief extract from the abbey's charter may serve to justify the extinction of this abbey. The abbot not only shared with the widow the money of a deceased tenant of the abbey lands, but among other oppressive exactions he claimed as heriots the deceased tenants' pigs, capons, horses, bees, and many other chattels. He also claimed the right of purchasing from them at any time a hen or duck for 2*d.*, and during Lent a duckling for 1½*d.* Piers Plowman with wise prescience saw that such injustice must be abolished, and foretold that the abbeys should receive "the knocke of a kynge." This "knocke" came from Henry VIII., and in the thirtieth year of his reign Vale Royal Abbey was surrendered, and three years subsequently was granted to Thomas Holcroft, one of the king's esquires. He pulled down the entire abbey and erected a mansion on the site, of which an engraving as it appeared in 1616 is in Ormerod's "History of Cheshire," and others of it in 1775 and 1819. Wings were added by Mr. Cholmondley in 1796, and various subsequent alterations have rendered it the mansion represented in our engraving. The cellars of the abbey remain under the mansion, and a subterranean passage, said to extend four miles, but now ruinous, and only traversable less than a fourth that distance. Such traditions, and legends like those of Nixon the Cheshire pro-

Vale Royal.

phet's foretellings relative to the Cholmondleys, usually attach to monastic localities.

The estate passed to Dame Mary Cholmondley, widow of Sir Hugh, in 1616; and in the following year, on his return from Scotland, James I. stayed four nights at Vale Royal with "the bold Ladie of Cheshire," and hunted her stags with his own hounds. Lady Cholmondley's fourth son was the ancestor of the present Lord Delamere, whose father was raised to the peerage by that title at the coronation of George IV.

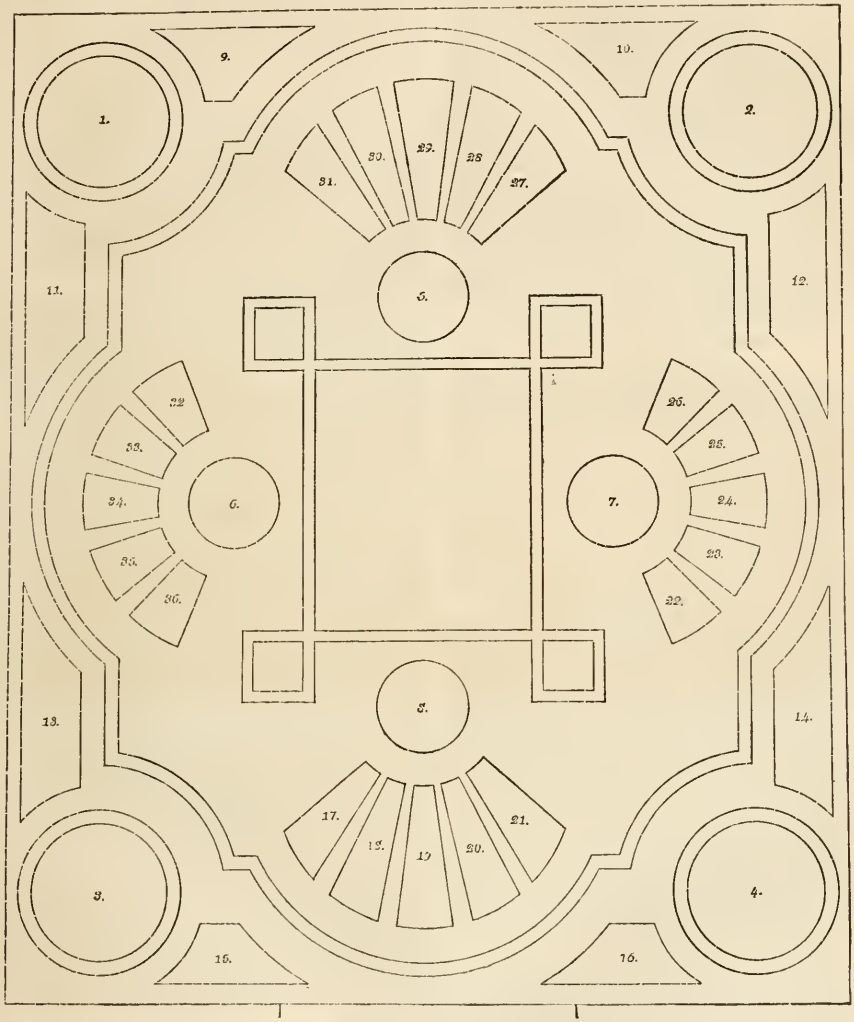
This fine estate is about four miles from the salt-manufacturing town of Northwich, near the centre of the county of Cheshire, and but a short distance from the eastern edge of Delamere forest, a part of which extends so as to join Vale Royal New Park.

The drive from Northwich is exceedingly pretty after leaving the highway, being for a considerable distance by the side of the river Weever, a navigable stream, which traverses a valley of the richest grass land. It has a winding course, first approaching one side of the valley and then the other, whilst in some places it seems to be hemmed-in. The carriage road skirts a wood which clothes the banks of one side of the valley, a wood of considerable beauty, both from the presence of overhanging trees and of masses of Rhododendrons on each side of the drive. The mansion, of which an engraving is annexed, is partly hidden from the approach by some noble trees, and it is not until we come quite close that the beauties of its architecture and position become apparent. At first sight it seems to be of small height, but this impression is no doubt due to the great expanse of ground over which it extends. It is built of the red sandstone of the district, and with its attached grounds occupies a somewhat elevated position.

The principal carriage entrance is to the north, and the garden and dressed grounds are to the south, east, and partly to the west, on which side the offices join the main building. To the south is a beautiful flower garden, including a series of beds forming a pleasing geometrical design, or rather two such, for a broad central walk divided the garden in two. The beds were filled to overflowing with the choice bedding plants of the day, and bounded on the west end by a fine ribbon border. This large flower garden is not the only one, for beyond a broad piece of ornamental water are more dressed ground and flower-beds, but more irregular, and intermixed with shrubs, specimen Conifers, and the like, with still more shrubs further in the south. Here is the kitchen garden effectively concealed by the shrubs, the mixed flower-beds by the edge of the water giving an ornamental appearance to the front. Entering the kitchen garden by a concealed path we soon reached the vinery, where were excellent Grapes and Peaches. The other contents of the forcing houses were equally good, as were the crops of vegetables of all kinds outside, to which the fine, deep, mellow soil is evidently well suited.

Where the dressed grounds approach the wood is a deep dell, the perpendicular descent into which cannot be less than from 80 to 100 feet, or more. This natural ravine contained some fine old Oaks, and the ground is thickly covered in most

places with Rhododendrons, amongst which there wound various walks, with seats and summer-houses at suitable points, and in the bottom was a level space, on which an artistic fountain and basin were placed. I am not sure but a dripping well or something of that kind, and for which the stream of water that runs down the middle could easily be made to do duty, would not be more appropriate. It was, however, a most lovely spot even in August, and must be still more so in May



FLOWER GARDEN AT VALE ROYAL.[1]

1, 2, 3, 4, Geranium Cybister, edged with Centaurea.
5, 6, 7, 8, Calceolaria Yellow Gem, edged with Perilla.
9, 10, 15, 16, Geranium Crystal Palace Gem, edged with Iresine Lindeni.
11, 12, 13, 14, Geranium Christine, edged with Iresine Lindeni.
17, 21, Geranium Beaton's Silver Nosegay.
18, 20, Purple King Verbena.
19, Robert Fish Geranium. All the other fan beds are planted the same as 17, 18, 19, 20.

In the centre of each half is the monogram—two D's in Box, within an oval of red brick.

The centre bed, not numbered in the plan, is about 2 feet wide, and planted with Geranium Flower of Spring one row, edged with blue Lobelia.

when the Rhododendrons are in flower. One thing especially attracted my attention, and that was a monument which the children of one of the Lady Delameres had erected to her honour towards the end of last century. The inscription upon it records the esteem in which she was held alike by rich and by poor, and its quiet repose under the shade of fine old trees gives a remarkable charm to the landscape.

Pursuing another route through the park, we come to a tract

of land resembling some of the wilds of Scotland, only of more limited extent. The rich grass herbage changes by degrees to a mixture of turf and Fern, and by-and-by the Fern usurps the whole space; while the Oak trees diminish in size, and are mixed with Birches and now and then Hollies. Many naked spots appear, but there is still beauty in the waving of the Fern in the sun, the branching tops of the Oaks and other trees, and the water in the distance. I should think there are few parks exhibiting such diversity as that of Vale Royal, though some have bolder features. The New Park, in which we now are, consists of gentle rising ground, and through it passes a broad carriage road. The poor shallow soil appears to be more of the character of yellow hungry gravel than a black peat, supporting the Fern without the Heath, but in the distance I could see large breadths of the latter.

Emerging from the park at a place where its wild features become softened a little, I found myself once more on the highway leading from Northwich to Chester, and I noticed that scarce a building in the High Street but had sunk either one way or the other, and had not cracks in its walls; the window-sills and door-heads were also several inches out of the level. I was told this was owing to the salt having been removed from underneath them. I believe the salt now made there is obtained from salt springs some distance off, the brine being conveyed in pipes to the works.—J. Robson.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Everything in the kitchen garden is now stirring. A proper rotation of crops having been secured, the next best advice is to watch the fluctuations of the weather, and to do all planting and sowing whilst the ground is in a mellow state. Prepare soil for new plantations of *Asparagus* where required. The first requisites are good fibrous loam and dung; when the soil in the garden is what is technically termed old, add a third of the whole of maiden loam, and good rotten dung to the depth of 6 inches over the surface. Trench the ground at least 3 feet deep, and drain it if necessary, then add as much more manure, and dig it in as deeply as is commonly done for general crops. Mark off beds 4 feet wide and 2 feet alleys; then mark the rows on the bed, one in the centre and one on each side, at 1 foot from it. Lay a ridge of equal parts of maiden loam, leaf mould, and sand in the line each row is to occupy, and on those ridges place the plants. They may be either one or two years old, but not more than two years, and they ought to be taken up with great care, so as not to break the point of a single root. When placed on the ridges, with an equal portion of roots on each side, cover the latter to the depth of 2 inches with pure sand when it can be procured; this will induce the plants to throw out a host of young roots, which, passing through the sand, seize with avidity on the more nutritious materials prepared for them. Above the sand put on 4 inches of loam over the crowns, and should the season prove dry, mulch between the rows with Spinach which has run to seed, or some similar covering, and give occasional waterings of liquid manure. If early spring-sown *Cauliflowers* and *Lettuces* are forward enough let them be pricked out. Earth-up *Cabbage* plants. Dig and manure the quarter intended for *Onions*. Plant *Potatoes* on a warm border. See to the due preparation of ground for crops in general, but do not work it when it is wet; better be a fortnight too late with any given crop. Where kitchen gardens are composed of light sandy soil, it is better dug and trenched several weeks before it is wanted for some crops. Broad Beans, for instance, like a firm hold of the soil.

FRUIT GARDEN.

Every care that fruit trees require in this season of inactivity, if not already bestowed, should at once be afforded. It is a good plan to place a piece of turf over the roots of trees recently planted. Decide on the system of training; the height of the wall and the space horizontally should be early considerations. Prune Raspberries; any Gooseberries and Currants not previously pruned should be forthwith attended to. Gooseberry and Currant trees occupy much less space in a garden if trained on stakes, and afford as much fruit as when in the bush form.

FLOWER GARDEN.

Complete all operations retarded by the weather, and proceed with pruning. Turf may be cut and laid, and wood ashes spread on lawns when the grass is injured by moss. American plants may be removed; it is often dangerous to remove Rhododendrons in the winter, as their delicate fibrous roots are liable to be injured by severe weather. Where the natural soil is not favourable for the growth of Rhododendrons, soil suitable for them may be gradually formed by sweeping the fallen leaves over the roots and covering them with sand every season. Attend well to thorough cleanliness; hoe through or otherwise dress all margins or beds where there are Crocuses, Snowdrops, and other spring flowers. Plant out Hollyhocks, which are well deserving of general cultivation. Their bold and pointed forms stand out in fine relief in masses of flat-headed shrubs. Owing to the absence of frost and the late singularly mild weather, collections of Tulips and other bulbs appear to be but little troubled with canker. When this occurs, and the plants are fairly above ground, cut away the parts with a sharp penknife. Shelter the beds from cutting winds, which are more detrimental than slight frosts. As seedling Polyanthuses come into bloom remove all that are inferior in shape, lacing, or colour. Amateurs have hardly been able to do wrong this season with Carnations and Picotees, and Stocks are looking well throughout the country. Continue the directions previously given, and keep the plants free from green fly; plant out seedlings in beds for blooming, retaining all the soil possible.

GREENHOUSE AND CONSERVATORY.

Among other important matters which belong to this early season, attending to raising certain plants from seeds is not the least important. There are many seeds of exotic herbaceous plants that should be encouraged to germinate early, that the plants may receive the full benefit of our summer, and attain that degree of maturity which enables them better to withstand the gloom and severity of our winters. I would recommend the sowing of exotic and other seeds, generally, during the present and following month. As hybridisation is now better understood and more generally practised than formerly, doubtless additional interest will be discovered in, and attention bestowed on, the propagation of plants by seeds. It is of importance to the anxious grower to bloom his plants the first season, and with many subjects it is only by sowing early that he is enabled to attain this result. Pelargoniums should be sown immediately, and kept growing from the moment they vegetate, to ensure a blossom the first year. As most seeds germinate under similar circumstances, a pit might be appropriated exclusively to the purpose. Beyond regulating the amount of heat, and supplying the seed pans with moisture, no extraordinary care is required. Rich soils are not to be recommended for sowing seeds. The character of the plants should determine in a measure the selection of soil. The admission of air on all favourable opportunities will conduce to the health, and keep the various flowering plants in unimpaired beauty for some weeks. Hyacinths, Lilacs, Kalmias, Azaleas, and Rhodoras introduced will lend beauty and fragrance to the various groups. The rich yellow flowers of Cytisus racemosus will add in no slight degree to the general effect. Kennedya Marryattæ is a charming greenhouse plant, and blossoming at this season it will be doubly valuable. For mixed greenhouses it is somewhat difficult to give precise directions. Plants of all climates occasionally obtain a place here, and no special treatment in regard to temperature can long be indulged in with impunity. As a principle, therefore, I would advise a rather free increase of heat on sunny days early in the afternoon for a few hours, sinking the temperature at night to the old point, or nearly so. In this structure there will frequently be found Ericas, Pelargoniums, New Holland plants, bulbs, &c. A division of these plants should therefore be made; let the Pelargoniums and other softwooded plants occupy the warmer end, and the Ericas, &c., the other, with a free circulation of air. A little Cineraria and Chinese Primrose seed may now be sown; this, with another sowing in April, will furnish a supply for the coming autumn and winter. Attend to ornamental trellis plants, which should be kept neat and orderly.

STOVE.

Exhausted winter-flowering plants in stoves may be cut back a little and left to break afresh, when they may be disrooted and placed in smaller pots; if all go well they will make fine specimens for next winter. Look over the Orchids, and see that the fastenings of those on blocks and in baskets are secure; renew the wires where necessary. Give a little fresh material to those not to be shifted, but beware of burying the buds on the eye of their pushing. Apply baits for snails and cockroaches, and attend closely to the extirpation of scale.

PITS.

Look out a quantity of the best and strongest plants of herbaceous Calceolarias; give them a good shift in a mixture of rough fibrous loam and coarse sharp sand. Place them in a genial bottom heat in frames or pits. A batch of Amaryllis bulbs should now be shaken out and repotted in half-decayed turfy loam, mixed with a small portion of saud. Give air freely to plants in store pots, such as Verbenas and Scarlet Geraniums, and carefully remove all decaying leaves.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE late fine weather has allowed us to get on with digging and trenching. Cauliflowers are now over, but we are still obliged to protect Snow's and other early Broccoli from the frost. Some Potatoes which had been started in boxes we transplanted into slightly warmed soil, where they seldom fail to do well.

There are several ways of growing early Potatoes—one, by placing the tubers in 3-inch pots, and when they are filled with roots, turning the plants out; another, by growing them right on in 8 or 12-inch pots, and earthing them up by degrees, or starting them as in the former case, and then transplanting into 8 or 12-inch pots. Another, and the best plan of all, is to grow them in 6-inch pots in a mild hotbed of about 50°, covered with a frame, and to earth-up as the plants increase in size. By this means, Potatoes can be obtained three weeks sooner than when treated in the usual way.

We have sown Radishes and Carrots in mild hotbeds somewhat more thickly than is customary, and we shall thin them out less than others do until we pull them for use. A bed of Early Horn or Early Dutch Carrots, if left to grow thickly and then thinned-out as soon as the roots are fit to be used, give the best returns we know of.

Sea-kale will yield its finest heads in the second year after sowing. It can be reproduced by means of pieces of the roots from the old plants, which should be planted in rows with their tops level with the surface of the soil, and covered with ashes and a little salt. These roots may be taken up and forced in the following autumn, and will do very well, but if allowed to remain a year longer before being disturbed they will in that case make most superb plants. I have found that this mode is more satisfactory than using the old crowns, and the plants from it are more forward than the most carefully tended seedlings.

We grow every year less particular about the materials we use for our Mushroom beds. We have small shallow beds so regulated that the spawned bed coming into bearing is aided by the heat arising from that which is being prepared. We shall, however, lay down no strict rules as to the mode of proceeding, as they can be altered so much according to circumstances. Rather young Cucumbers in a pit with but little light in winter, allowed to bear heavily from the middle of November to the end of January, will become very inferior after this time, and will not, even with coaxing, do so well as young plants. If we want a regular winter or spring supply we keep the plants moderately strong through December, but do not let the fruit swell until the New Year is passed.

ORNAMENTAL DEPARTMENT.

The weather is splendid for planting and transplanting, provided, in the latter case, that the ground is not soaked. The best mode, to our way of thinking, of securing newly-planted trees is by means of three fir poles driven in 6 feet from the base of the tree triangularly, and brought together by a circular band of straw ropes at 10 feet from the ground. For preventing evaporation from the bark of trees, and also for keeping off the attacks of cattle, straw or hay ropes twisted round the trunks, and then tarred, may be used.—R. F.

Teutschel & Co., Colchester.—*List of Japanese Lilies, Maples, Seeds, &c.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

BOOKS (*C. J. W.*).—"The Gallery of Nature," by the Rev. T. Milner, will suit you. It is a very full and beautiful "pictorial and descriptive tour through creation." Its price is about 20*s.*

POTATOES UNFIT FOR TABLE (*B. T.*)—The tubers are small and hard, owing to the undrained clayey subsoil. Drain it, and if the surface soil is also clayey, pare and burn 6 inches deep of it, and incorporate the ashes with the remaining surface soil. Grow Ashleaved Kidneys and Lapstone Kidneys.

VINES FAILING (*B. W.*).—Your case is not an uncommon one, as there are many such failures. You are now, however, on a fair way to success. We should not start the Vines until March, and then give no more than a gentle fire heat in cold periods, so as to keep the temperature from falling below 50 at night; in fact, allow the Vines to start naturally, and apply heat at a later period to insure the thorough ripening of the wood.

RHODODENDRONS PRUNING (*S. E. M. J. W.*).—You may cut them down to about 18 inches from the ground, when they will shoot again freely, though usually they do not do much during the first year. Cut back about the second week in April, and in showery weather if possible.

VITALITY OF SEEDS (*William Jones*).—All the kinds of seeds named will keep good until the second or even third year, and many much longer, but we would not sow any of them after the second year, as their germinating power is very weak, and they do not afford nearly such good plants as fresh seeds, even if they grow.

CUPRESSUS LAWSONIANA SEEDS SOWING (*T. Ashton*).—In March sow them amongst light sandy soil in pans, and place them in a cold frame. Keep them close until they come up, and then admit air freely and expose them fully. In autumn prick them off into store pots, and winter them in a cold frame or house, admitting abundance of air. In March they may be put out in rows 18 inches apart, at a distance of 1 foot from one another. In the course of three years they will be fine plants, and may be planted out permanently. The less "coddling" they have the better.

SOIL FOR POTTED PALMS (*C. B.*).—Use a compost consisting of loam two parts, peat one part, well-decomposed manure one part; and a sufficient quantity of sharp sand must be added to make the whole feel gritty when taken in the hand. For seedlings or very young plants, however, we have always found them grow more rapidly if the quantities of loam and peat are reversed; thus, instead of two parts loam, put two parts peat and one only of loam.

AMARYLLIS BULBS PLANTING (*Amaryllis*).—You need be under no apprehension respecting the covering of your bulbs of Amaryllis; there is no more fear of their rotting from that cause than there is with border Hyacinths, Liliums, Tulips, and many other bulbous plants which no one thinks of growing above the soil.

TROPŒOLUMS LATE PLANTED (*M. S. B.*).—We think that the roots of those that were not planted or potted until January will not flower this year, though they may do so very late. Their chance of blooming would have been better had the long white shoots not been cut off. We should keep them in a house with a night temperature of 45° to 50°. It is necessary that they should make good growth if they are to do well another season. They should be potted at the close of August or early in September.

PAINTING STOVE AND GREENHOUSE (*Idem*).—As the houses are cleared of the plants there is nothing to prevent your having them thoroughly cleaned and painted. Do not bring the plants in again until the paint is dried, which can be facilitated by giving air freely, and keeping up a good heat. There is no need to use anything to take away the smell of the paint, but air should be admitted rather more freely for a few days after the plants are put back again, to keep them from injury and to harden the paint. Thoroughly clean the woodwork with soap and water before painting; also clean the glass with pure water, taking care to keep the soapy water from it.

POTATOES SPROUTED (*Ignoramus*).—Remove the Early Rose with shoots 3 inches long, and place them thinly in a warm position (50°), so that they may sprout again freely. It is well, however, not to remove the first shoots of early kinds, as some are very deficient of eyes, and not unfrequently put out a second time very weakly shoots or none at all. Ours have put forth shoots about half an inch long, and are on lath shelves in single layers, receiving air daily, and protected from frost. With the present and late mild weather it is difficult to keep the early sorts from sprouting too much.

PLANTING QUICKS (*A Subscriber*).—We consider one row of Quicks preferable to two, for the simple reason that it is much more quickly and cheaply cleaned, which is the grand secret of getting a hedge to grow. If your ground is poor add manure liberally, and dig deeply. Plant the Quicks 4 to 4½ inches apart, and when from 2 to 2½ feet high. Holly and Thorn make a good semi-evergreen hedge, but for rapid growth Thorn is preferable. The other is the neater hedge. Now is a good time to plant Hollies 1 to 2 feet high that have been recently transplanted. Hollies require to be lifted with good roots, and to secure these frequent transplanting is necessary. If you have Holly and Thorn, five Thorns and one Holly per yard will be needed.

CHRYSANTHEMUMS NOT FLOWERING (*Smith*).—The cause is probably stopping the plants too late, and the buds consequently not having formed until November or later. We have some similarly affected. It is owing to the cold and wet of last season, for the year before, by the same means, we had in January and February fine blooms from plants stopped early in August. We presume yours were treated for a late bloom, which at the best is hazardous, but well worth endeavouring to secure. The weather may be more favourable this year.

CARROTS AND PARSNIPS FOR EXHIBITION (*A Subscriber*).—To make holes at every 9 inches in the rows and fill them with sand is good, but though we should make them 16 inches deep if the soil were stiff, we would not fill them with sand alone, but with fine sandy soil, then sow three or four seeds over each, and single out to one plant in each hole. If the ground is well pulverised to the depth of 18 inches or 2 feet, light, sandy, and rich, the holes are unnecessary.

ONIONS FOR EXHIBITION (*Idem*).—New Giant Rocca, Dauvers' Yellow, Naseby Mammoth, and Bedfordshire Champion. Of Tripolis, Giant White, Large Italian Red, and Red Mammoth.

TWELVE HARDY GRASSES (*Idem*).—Agrostis nebulosa, hardy annual; Carex leporina, hardy perennial; Elensine distans, annual; Hordeum jubatum, annual; Stipa elegantissima, perennial; Pennisetum setosum, annual; Pas-

palum elegans; Gnaphalium argenteum, perennial; Briza geniculata, annual; Anthoxanthum gracile, annual; Piptatherum Thomasi, annual, and Hordeum jubatum, annual. Sow in pans at the beginning of April, place in a cold frame or in gentle heat, and when up admit air freely. When the seedlings are fit to handle plant out in good soil in an open situation. The perennials should be potted off singly, and grown on in a frame, planting out the first two about a foot apart, and the others will do at that distance the first year, and the second year should be a yard apart. Remove every alternate plant of the two perennials first named. Give Equid manure in hot dry weather.

MANURING YEW HEDGES (*Surrey*).—Manuring every year is not necessary; but as you wish for speedy growth we should top-dress with manure and leave it on the surface, as it cannot well be dug in without causing more or less injury to the roots. Old manure mixed with leaf soil and turf parings would be a good top-dressing for the Yews, Retinospores, and Chinese Junipers, but we would not dig it in; we would merely loosen the surface and put on the top-dressing an inch or two thick. By cutting the tops, and not the sides of the Yews, in April, you will cause them to break lower down.

FLOWER-BED PLANTING (*Idem*).—For the star beds you may have Golden Pyrethrum, Alternanthera magnifica, with Antennaria tomentosa for edging. Let the circle be of the first, with a plant of Centaurea in the middle; fill up the points with the Alternanthera, and edge with the Antennaria. Another bed you can have edged with Arabis alpina variegata aurea, filling the points of the star with Ajuga reptans rubra, a circle of Centaurea ragusina compacta, and a small plant of Abutilon Thompsoni in the centre. Another bed you may have edged with Oxalis tropæoloides, the points of the star filled with Santolina incana, a circle of Iresine Lindeni, and in the centre a plant of Coprosma Baueriana variegata. The other bed may be edged with Sempervivum californicum, the points filled with Golden Pyrethrum, a circle of Echeveria metallica, with Dactylis glomerata elegantissima for the centre plant.

BASIN FOR WATER LILIES (*Idem*).—It should have at the bottom about a foot deep of mud formed of any good rich loam, and over that water to the depth of 18 inches or 2 feet. They should be planted in April, and flower in July and August. The Yellow Water Lily (Nuphar lutea), is the first to bloom, and Nymphæa alba or the White Water Lily last. They may be had of the principal nurserymen advertising in our columns. We cannot depart from our rule not to recommend dealers.

JASMINUM FRUTICANS—SOWING ORANGE PIPS (*Alcar*).—Small trees can be grown from pips; sow them now, and place the pot in a hothouse. The soil should be sandy loam with a little leaf mould added. We do not think your Jasminum fruticans will flower in the ensuing summer. It is a dwarf, hardy, deciduous species from the south of Europe. You may plant out at once.

BONES FOR VINE BORDER (*M.*).—Your arrangement is correct, but you should place at least 9 inches of broken bricks or some similar material over the bottom before filling in the compost. The soil would then be 2 feet 3 inches deep, and the border will contain rather more than 12 yards of the compost. Four hundredweight of what are called inch bones will be sufficient. We cannot recommend dealers.

WIRE FOR HYACINTHS (*Joseph Smith*).—You will find wire supports for Hyacinths in glasses at any respectable seedsman's. We see them daily in the seed shops of London.

GEORGE'S CALORIGEN (*H. H.*).—We have had no experience of George's calorigen, and are sorry we cannot give you any further information about it, except what appears in the advertisements.

CORDON TREES (*Amateur*).—1st, No harm will come to cordon trees arising out of the freshness of the wall, if planted against a wall just built. 2nd, The cordons may be inclined either to the right or the left; they are generally bent to the right. Plant them 16 to 18 inches apart, shorten them about one-third of their length, and nail them to the wall the first year at an angle of 60°. When you have the lower part well furnished with spurs, which will be at the end of the second autumn after planting, fix the inclination permanently at 45°.

SIX HARDY ANNUALS FOR CLUMPS (*F. J.*).—Alyssum maritimum, white; Leptosiphon densiflorus, lilac; Linum grandiflorum coccineum, crimson; Nasturtium King of Tom Thumbs, scarlet; Nasturtium King of Tom Thumbs, golden yellow; and Saponaria calabrica, pink. They are of compact growth, under a foot or about a foot in height, and bloom a long time. Lobelias and Ageratum Imperial Dwarf come true from seed, and bloom as freely as from cuttings, but the plants are somewhat stronger, and are later in flowering. On the north border we do not know of anything that will do so well as Calceolarias. We would have Perilla at the back, then yellow Calceolarias, and an edging of Lobelia. Between the newly-planted Apple and Pear trees you may have a row of dwarf Peas, as Little Gem, and small-topped Potatoes, and even Cauliflowers; but we should only have one row between every two rows of Apple or Pear trees.

DISTINGUISHING POTATOES BY THE SPROUTS—SELECT ROSES—VARIOUS (*Fair West*).—You ask us "Why Sandringham Kidney Potato was last year in catalogues as a novelty, and is not mentioned this year?" It is named in the catalogues as a novelty, and is not mentioned this year? The Potato that has dark bluish-green sprouts we should first we looked into. The Potato that has dark bluish-green sprouts we should say is Royal Ashleaf, and the other with very light sprouts, the colour of forced Asparagus, we should consider Sandringham, but we cannot be certain. As you have grown both before, you will be able to distinguish them by the growth. We do not know how you will be able to insure the dryness of the wall without repairing the thatched roof, and that will enable you to plant your tree at the place you wish. We do not understand the purport of your third question. The site of the garden is good, but the elevation will not counterbalance the moisture of the climate. You may bud the summer Roses with Perpetuals, or replace them with the latter. These will do wherever the others will. You could probably obtain buds at the proper time from some friend. A dozen Roses are—Baroness Rothschild, Alfred Colomb, Dr. Andry, Edward Morren, John Hopper, Charles Lefebvre, La France, Senateur Vaisse, Perfection de Lyon, Thorin, Mdlle. Marie Rady, Pierre Notting, and Xavier Olibn, all Hybrid Perpetuals; Gloire de Dijon, Tea-scented; and for the wall, Alice Grey, Dundee Rambler, and Queen. The wall is not good enough for Noisettes or Teas. The Fern is Polypodium vulgare. Bellegarde Onion requires to be sown like any other—namely, as soon after the present time as the ground is in good working order. Angelica de Niort sow in drills a foot apart, and half an inch deep, and thin out the plants to 2 feet 6 inches from each other when 6 inches high, or you may put in a few seeds in a patch at the distances named, and thin out the seedlings in each patch to one. It requires moist soil. Sow Melilotus cærulea in common soil in March. Sow Gourds in a hotbed early in April, and plant out in May after hardening-off. Grow the Melon in frames. Sow the varieties of Delphinium elatum in the open ground in April, and plant out 3 feet apart. Sow tree Carnations in pans in gentle heat, harden off the young plants, and prick them out a foot apart. Take them up with balls in autumn, and winter them in a frame or house. Plant Chinese Yams 18 inches apart, in rows 4 feet asunder, taking out soil between the trenches so as to cover them a foot deep.

HEATING A SMALL GREENHOUSE (*H. N. O.*).—We think the stove you refer to would be perfectly safe, especially if a quarter-of-an-inch iron pipe led from the burner into the open air. Then the water-can or cistern would give off moisture uncontaminated by the effects of the combustion of the oil. For common purposes this would not be necessary. For such a place we ourselves would be quite satisfied with a small iron stove, and a pan of water over it. Certainly a lamp may be more easily managed. The hydronettes, or hydropults, merely want to be placed in a bucket of water; they have all the force in themselves.

ECONOMICAL LEAN-TO GREENHOUSE—GAS-HEATING (*Tenet*).—The cheapest way to construct a small house is to have air in front and at top, and the roof fixed, without sashes, having the sash-bars from 15 to 18 inches apart. For such a small house 20 feet by 8 feet, we would not trouble with ventilators at all if we could have a moveable ventilator at each end, say as much as 2 feet square, under the apex. In very hot weather in summer the door could stand open, and these end ventilators could stand open night and day. For gas-heating refer to No. 341, where full details are given. No mode of heating is so dangerous unless all the fumes are carried off.

GREENHOUSE RAFTERS (*R. Brace*).—As we cannot find the answer to your former question we can give but imperfect advice with respect to the distance of the rafters, the weight of the glass, and the size of the panes. We may add, that rafter sash-bars from 15 to 18 inches apart will support glass from 26 to 24-oz. weight, that a good weight is 21-oz., and supposing the rafters to be 18 inches apart, a good size for the squares will be 18 by 12 inches.

MUSHROOM CULTURE (*T. Porter*).—We have grown Mushrooms in large earthenware pots and moveable wooden boxes 18 inches square, bringing them in in rotation, and we were well supplied. For a regular bed one 3 feet square is too small, and this, as evil in itself, is aggravated by having hot-water pipes passing through these small beds. We never found pipes or flues passing through such beds of any advantage. The boiler at the other end of the shed-house will give heat enough. We have had beds a mass of whiteness in sheds at the back of greenhouses, and at the back of forcing houses, but we should like them to be at least four times the size of yours, and we would keep the temperature uniform with a little rough-hay covering, and keep the atmosphere moist by sprinkling the floor, walks, and walls.

MAKING A HOTBED OF LEAVES (*H. A. L.*).—The leaves need no preparation beyond wetting them if they are dry. We prefer mixing them with their own bulk of stable litter that has been thrown in a heap, turned over once or twice, and watered to bring it to a good heat. Mix this litter with the leaves on making up the bed, putting the littery parts of the manure at the sides, so as to keep the bed together. A bed 4 feet high in front, 5 feet high at back, 18 inches wider than the frame all round, and well beaten down with the fork 18 inches wider than the frame all round, and well beaten down with the fork in making it up, will be a good and durable hotbed, which, with linings, will be suitable for cuttings or seeds, and Cucumbers or Melons. The heat will continue for six weeks; indeed, we had a bed of leaves and litter made at the end of November, and it has still a good heat; it is, of course, well lined with hot dung.

CAMELLIAS AS HARDY SHRUBS (*Subscriber*).—These may in warm sheltered nooks in the far south or south-western counties succeed as hardy shrubs, but we fear they would not thrive as such in Surrey, though we have no fear of their doing well against a wall with a south-west or west aspect. At Southampton we know a wall covered with Camellias, which bloom well and have no protection, and in Yorkshire we have seen a plant of Alba plena with three hundred expanded flowers in January, in a house without any artificial heat.

BEGONIAS DAMPING (*W. H.*).—At this season they require very little water. Keep them no more than just moist; potting in November would tend to cause them to go off. Let them have a temperature of 50°, and they will soon commence to grow freely. The leaf you sent is of Lucinda grandiflora. As the flowers damp-off give more air and a temperature of 45° to 50°. Do not water at the roots until the soil becomes dry, then give a good supply.

DOUBLE-FLOWERED GERANIUM (*Henri*).—The plants which bloomed late should be cut-in now, shortening each shoot to within a few eyes of its base. When the plants have made fresh shoots about an inch long, turn them out of the pots, shake off the old soil, and place them in 6-inch pots; shift into 8-inch pots when they have filled the others with roots, and again into 10-inch pots if you wish to have large plants. Those which were struck last May, and are in 5-inch pots, may be cut back if straggling; if not, they should be stopped, shaken out, and repotted in the same size, shifting them into larger pots as required. The plants from cuttings struck last autumn will only need to be cut back to three or four eyes, shifting afresh into larger pots after they have started. The parts cut off will strike freely in gentle heat. The turf you laid up last autumn will now be in good order for potting; chop it up well. It would be the better of the addition of sand for plants, and for cuttings sand is essential.

HARDY ANNUALS FOR EARLY FLOWERING (*Idem*).—Bartonia aurea, Centranthus macrosiphon, Chrysanthemum Burridgeanum, Clarkia pulchella marginata flore-pleno, Branching Larkspur, Leptosiphon densiflorus, Linum grandiflorum coccineum, Lupinus subcarnosus, Nasturtium Tom Thumb variegated, Saponaria calabrica, Silene pendula ruberrima, and Whitlavia grandiflora. Sow early in April in rich light soil in an open border, in patches a foot or more across, covering the seeds with very fine soil. Water if the weather be dry, and thin out the seedlings to 2 to 3 inches apart when they are about an inch high.

IMPROVING GARDEN SOIL (*S. R.*).—We would trench the ground that has not been dug for a number of years and pulverise it as much as possible. For all root crops we would place the manure between the layers of soil in the trenching—that is, we would place the top soil at the bottom of the trench, and manure, mixing the manure with the bottom spit by means of a fork, then turn on the bottom spit, well breaking the clods, and before sowing fork well so as to have the surface in good tilth. For Peas, Cauliflowers, and Potatoes we should manure on the surface and fork-in the manure. We think, without manure, your prospect of good crops will be bad. The part with about 9 inches of loam over a bed of ashes or cinder rubbish many feet deep would be much improved by putting a layer of vegetable refuse on the cinders and making the soil at least 15 inches deep. Make the soil as nearly 2 feet deep as you can, manure liberally, and there is not any kind of vegetable crop that would not do well in this part. It will suit Potatoes very well, the good drainage tending to cause early maturity.

Growing late Melons in Frames (*Amateur*).—By sowing the seeds about the middle of March, and shifting the plants into larger pots as required, you may fruit them early in August by planting them in a frame in June. The plants will have set fruit earlier than the planting-out time, and it is just as well to plunge the pots in the bed, so that the roots may come over the top, or they may be planted out. We would not sow until the beginning of May, and would grow the plants in pots, so as to have them strong for planting-out when the frame is ready, and with linings you have every prospect of a crop of late Melons in September.

White Bedding Pansy (*Idem*).—The best white Pansy for early summer flowering is Cliveden White, and for summer late-struck cuttings Viola cornuta alba planted in spring, and well supplied with water in dry weather.

Geranium Cuttings (*Idem*).—The beginning of March is not too early to prick out on a gentle hotbed, autumn-struck cuttings of Tricolor, Bicolor, and Bedding Geraniums, giving them air liberally after a few days. It will be necessary to cover the lights after a few days to keep up a suitable temperature. We should place about a handful of soil to each plant, and tie up in moss. You may then move the plants with good balls.

Our Back Volumes (*A Young Gardener*).—They all contain communications from the writers you name; and so do many of the Manuals and volumes published at our office.

Geranium (*Amy*).—Any of the principal florists who advertise in our columns could supply the variety you name.

Geranium Leaves Yellow (*C. P.*).—The leaves appear to have been kept in a close, damp, and cold atmosphere, with more than enough water at the roots. Give the plants a temperature of from 45° to 50° at night, and admit air freely, watering moderately at the root, and only when the soil becomes dry. We would further advise you to shake out the plants, free them of the old soil, and pot them in turfy loam, with one part leaf soil or old dry manure added, and a free admixture of sand. We think they will come round.

Crickets in a Forcing House (*Edward Horne*).—They are best destroyed by poison. Entice them for two or three nights with six tablespoonfuls of oatmeal mixed with a teaspoonful of aniseed and a like quantity of carraway seed, brought to the consistency of a crumbling paste with honey. If they devour these baits greedily, then on the third night add to half a pint of the oatmeal a tablespoonful of ground anise and carraway seed, and 1 oz. of arsenic. Mix thoroughly with honey, and put down the mixture pellets about the size of marbles. Chase's beetle poison is also excellent and kills them on the spot. Phosphor paste they likewise eat greedily, and it also kills them. Be careful in removing the poisoned material, and to prevent domestic animals getting at it.

Plants for Unheated Conservatory with a North Aspect (*W. T.*).—The most suitable will be hardy Ferns and hardy fine-foliaged plants, or such as require but slight protection. Of hardy Ferns, which may either be grown in rockwork and planted out, or in pots, we advise:—Adiantum Capillus-Veneris, Asplenium Adiantum-nigrum, A. marinum, A. Trichomanes, and A. Trichomanes cristatum; Athyrium Filix-fœmina, varieties corymbiferum, plumosum, multifidum, and depauperatum; Blechnum Spicant ramosum, Lastrea cristata major, L. opaca, L. Filix-mas cristata, Lomaria chilensis, Osmunda regalis cristata, Polypodium alpestre, P. Dryopteris, P. vulgare cambricum, Polystichum aculeatum, P. angulare cristatum, P. angulare pauliferum, Scolopendrium vulgare, varieties corymbiferum, crispum maximum, ramo-cristatum, submarginatum, and subcornutum, and Woodwardia radicans. The dwarfness of these may be relieved by a few plants with fine foliage, as Yucca aloifolia and variegata, Y. filamentosa and variegata, Y. quadricolor; Aralia Sieboldi and variegata, Araucaria excelsa, Retinospora plumosa, and others of the more compact and graceful-habited Conifers. A few plants of the new sorts, especially the berried sorts, come in well for such houses.

Names of Plants (*J. Lock*).—1, Echeveria glauca; 2, E. gibbiflora var. metallica, the E. metallica of gardeners. (*J. W.*).—The scraps sent are insufficient for determination. No. 2 might possibly belong to Pachysandra terminalis. (*Thos. Mayes*).—The "Wild Flowers" can be had as you desire, monthly from the beginning. We do not recommend you to use the Reindeer Moss (Cladonia rangiferina), enclosed by you, as a substitute for sphagnum. Possibly it may answer well in some cases, but we prefer sphagnum. The Orchid flowers were in very indifferent condition. 1 Appears to be a cymbidium sinense; 2, Dendrobium Pierardi. Well-rotted cow dung may safely be used for the coarser terrestrial Orchids, as Phajus grandifolius and Wallichii, Peristeria elata, &c., but of course must not be used with Cattleyas, Odontoglots, or other epiphytal species. Peat answers very well indeed for many Orchids when wired to the block instead of sphagnum, and it is not unusual to find a plant growing on a block subsequently partly sunk into a pot containing a compost of rough peat, with its accompaniment of charcoal and crocks. (*A. B. C.*).—Winter Aconite, Eranthis hyemalis. (*Huthwaite*).—1, Not in a condition fit for determination; certainly some Leguminous herb, possibly an Astragalus. 2, Habrothamnus fasciculatus.

POULTRY, BEE, AND PIGEON CHRONICLE.

MANAGEMENT OF FOWLS AT SHOWS.

Would you allow me, as a rather old breeder of fowls, to make a few remarks on the two letters in your Journal, signed by "Winner of Four Cups" and "James Clare?" The reason of poultry suffering so much from exhibition arises mostly, if not entirely, from, firstly, the unnatural state the birds are in when sent to the show; secondly, from the want of pure air in the exhibition pens; and probably, thirdly, from the birds being partially fed on some of the rubbishy mixtures called fowl foods—rather I would say *foul* foods.

With regard to the first point, it is well known to all experienced keepers of animals that it is much easier to get them into high condition than to keep them so. It seems to be almost the natural state of things, as soon as an animal has attained a certain state of perfection, that it should begin instantly to go back—that is, if you have poultry in such a condition as to be "fit to show anywhere," and then turn them down in as a healthy run as you can meet with, you will find they will not keep in this condition, but go back. Now if this is allowed to be the case (and I think few large breeders of prize poultry will fail to do so), is it at all strange that fowls penned-up in a dirty pen, or in hot close hampers or baskets, should go much more rapidly out of condition than they would at their owners' yards, and that they are very liable to those diseases caused by bad air? I say nothing about there not unlikely being diseased fowls actually at the show. It is, I believe, well known as a case in point that dogs, if sent to a show before they have had distemper, are very liable to have it as soon as they reach home. Now no one would say that improper food, or the want of a certain kind of food, will cause distemper, nor will anyone say because a healthy young dog gets distemper, that therefore there was actually some dog at the same show that had the disease at the time.

I believe that the birds your correspondents refer to were suffering from diseased livers, such being in an unhealthy state when sent to the show; if so, the ale was about the worst thing possible for them. My plan, when birds come home, is to give them nothing but warm bread and skim milk; if they look dull in the morning, a pill of simply one grain of calomel, continuing the bread and milk. That birds do not suffer from want of lime and gravel is perfectly clear to my mind, at any rate as respects cocks. I have a lot of Game cocks in pens 3 to 4 feet every way; they are fed on Indian corn, barley, and every other day a little boiled rice and skimmed milk. They are all in perfect health, though they have been penned for six or eight weeks, and look better than their brothers running at large with the hens. The pens—and here is the grand secret—are covered at the bottom with sawdust, and every day a handful or two is thrown over it, dusted over it I might say; the consequence is that with the exception of the smell of sawdust my pens and henhouses are quite sweet. I adopt the same plan with my henhouses, only in them the sawdust is about 2 inches deep all over the bottom. If all secretaries of shows would adopt this plan I should send valuable birds for exhibition with far greater pleasure than I now do. It is astonishing how soon a lad can go over a lot of pens, and how little sawdust makes things sweet. I find the same plan succeed with my chickens; and though I was warned that if the birds, young or old, ate the dust—as they cannot help doing when fed with soft food—it would kill them, it has not done so with me.

I find at some shows exhibitors have said sawdust killed their birds, and to avoid this the secretaries had spread at the bottom chaff (chopped straw), which is almost as bad a material as could be used. The same remark applies to sand gravel, for this reason, that it being the nature of fowls generally, as well as when at exhibitions, to have loose watery evacuations which are every moment giving out unhealthy fumes, it is absolutely necessary for the birds' health either to be constantly removing this liquid, which cannot be done in shows, or to deodorise it by means of sawdust or earth, and the former is after all almost the only readily attained article that can be had, and that anywhere.

I hope the bird referred to by your correspondent will recover his comb. I have known of cases in which the comb turned quite as black as he mentions, and yet came all right again. The only cases in which, according to my experience, this does not happen are where frostbite is the cause, and then I fear it is hopeless to expect any improvement. I wish your correspondents would try the sawdust plan and let your readers know the result. Would they also say what the exhibition birds were fed upon before sending them to exhibitions? as I find that birds if too highly fed will appear in perfect health, be going on quite well, and suddenly show that their livers are out of order—in fact, as I said before, they seem to thrive up to a certain point and then rapidly go back.—Amateur.

PURE-BRED versus CROSS-BRED FOWLS.

I should gladly be of Mr. Fraser's opinion that pure-bred fowls produce as many eggs as cross-bred, or even more, but my experience has invariably disproved such a result being the case. My fowls are kept in close confinement with the exception of an occasional run in the garden, and I have now a pullet (by a Dorking cock from a cross-bred hen), hatched at the end of April, which has just laid her hundredth egg, none weighing less than 2 ozs. She commenced laying at the beginning of October, is still in perfect health and condition, shows no signs of becoming broody, and promises to accomplish still greater things. Not one of my pure Brahmas kept under pre

cisely similar circumstances and costing more for food can at all approach this amount of produce; and I may also mention that to this pullet an accident happened in August, which caused her to limp about on little more than one leg for several weeks, and of course threw her back considerably. This is merely an instance and not a solitary exception, and I shall be glad to learn how to keep pure-breds (my hobby) as profitably as mongrels.—JOHN WALTON, *Croydon.*

THE JUDGING AT POULTRY SHOWS.

"D., *Deal*," (in No. 564), has taken up a subject which needs careful and impartial investigation both by the committees of poultry shows and judges. How often do we see the judgment at poultry shows called in question! In fact, I have often noticed in reports in your Journal that pen so-and-so ought to have taken the place of the first, second, or third-prize pen. Of course, we amateurs take your Journal to be an impartial authority, and (I can only speak of myself) your reports are generally highly interesting. Now it is very annoying to any person to think that he is unjustly treated, and to see it in print makes the matter ten times worse. How, then, does this mistaken judgment occur? It may be, as "D., *Deal*," suggests, that there are too few judges and too little time allowed for judging. We must all admit that the task of the judges is a very arduous and often unthankful one. But why, if there is too little time allowed for judging, do the judges undertake those arduous duties? Why do they not raise their voices, one and all, against this unjust practice, and tell the committees plainly that they will not undertake to do what they cannot possibly do honestly towards the exhibitors, and with credit and satisfaction to themselves? But let me suggest, Are there not other causes in relation to judging besides the too-little time allowed for judging? Does it follow that because a man is a good judge of Game he is also a good judge of Brahmas, Spanish, Dorkings, Hamburghs, or many other varieties? Everyone has his peculiar fancy in fowls as in other things, and it seems to me that it is impossible for one man to be capable of judging the whole of the varieties satisfactorily. Much may be written on the above subject, but all to no purpose. It occurs to me that the matter rests mostly with the exhibitors and committees of the various shows.

If the funds of any society will not admit of the proper number of judges being engaged, I would suggest that the fees be made up equally amongst the exhibitors to provide any extra judges that may be required. Clearly something must be done to make matters more satisfactory than they are at present. Now is the time for suggestions, and if those who have grievances do not avail themselves of the opportunity of making them known, it is neither the fault of the judges nor of the committees.—AMATEUR.

DUBLIN POULTRY AND PIGEON SHOW.

I WAS never more astonished than at the very unfair comment on the Pigeons at this Show, made by "A CORRESPONDENT" in your Journal of February 1st. I did not exhibit at the above Show, so this cannot be put down to disappointment.

The Pouters were judged according to the Scotch manner, which excludes the use of the tape, and which accounts for the success of the Glasgow and Belfast birds, about which there is not a word in the report. These were well proportioned as regards length of feather and limb, narrowness of girth, with fine style and carriage, looking as well off the block as on it, carrying themselves properly, and seeming to know how to manage their tails. The majority of the English and Dublin birds were longer in feather (which ought to be considered a bad property unless combined with good points), and some of extraordinary length; when off the block their bodies were almost at right angles with their legs, caused by the great length of tail (cutting an inch or two off might improve them); in fact, they were all tail, and it appeared to be always in their way. They were runtish, and lacked shape and style. A Scotch fancier remarked to me that the use of the tape was all that was necessary to judge a Pouter in England. Some of the unnoticed Barbs were hardly able to see, they were so bunged up from old age, and were in a nasty scabby condition; their necks should have been wrung long ago. The first-prize Yellow Agates had a suspicious look about their very short beaks, and most of the Short-faced birds were in the same condition. Nobody to whom I spoke seemed to think that "Mr. Waitt's best birds" should have had a prize in the class for Reds and Yellows. If they were specimens of "Mr. Waitt's best," I wonder what his second best are like. Everyone said that the third-prize Reds should have been first. They were two cocks, which seemed to escape the Judges' notice. Mr. Waitt's Blacks should have been disqualified, as they were trimmed in the most barefaced manner, but "these were unnoticed" very properly, as there were better in the class. The correspondent was quite right in his remarks on the Fantails. Though the first-prize Blue English Owls had slightly whitish rumps, still, for all that, they were the best. He says about Turbits that "Mr. P. H. Jones's Reds should have been first, with Mr. Fielding's Reds and Mr. Horner's Blacks to follow." I did not meet anyone in the Show who thought so, except, perhaps, the owners, whom I have not the honour of knowing. Mr. Seale was first and third, and Mr. Tivy second. Your correspondent probably thought that such comparatively new and unknown exhibitors as Mr. Seale and Mr. Tivy could not possibly have superior birds, and had no right to prizes. Pigeons of the best strains have been imported into Ireland within the last few years, and English exhibitors will have to make up their minds to acknowledge that they have been fairly defeated.

In reporting on Pigeon shows, I think that it is very unfair to pass over prize birds without any comment on them, which is tantamount to saying that they were not worth noticing. The first, second, and third prizes should be all noticed, with owners' names mentioned, or there should be no comment allowed at all. Condition, cleanliness, &c., should be taken into account when judging, which would prevent exhibitors from sending the same pair of birds to shows until they are fagged to death by overshowing.

The Committee of the Dublin Show made a good rule, that anyone guilty of a dishonourable practice would be disqualified and lose all prizes that he might become entitled to; and I would suggest that the disqualified birds be sold by auction for the benefit of the society. This did not prevent trimming, &c., as there were several Nuns and Jacobins trimmed, several couples of cocks, and several couples of hens; Tumblers and Barbs with burned beaks; and Black Mottles dyed over the beak. Why were none of these disqualified? An exhibitor who would exhibit his birds in their natural state is compelled, in self-defence, to "do in Rome as the Romans do," or, if he does not, what chance of a prize has he, when a worse bird than his can be made better by a clever hand? It is all this sort of work that prevents many from showing both poultry and Pigeons, and which drives so many from these fancies. I perceive one thing—that if ever I should become an exhibitor, unless things are changed, I must go in for all the dirty work at present in vogue. As I do not believe in anonymous contributions, I give my name, and expect that your correspondent will give his.—J. CROSBIE SMITH, *Terenure Villa, Terenure, Dublin.*

[After omitting many sentences pointed against the supposed contributor whom we styled "A CORRESPONDENT," and many other sentences ascribing motives and assailing supposed cliques, we readily insert the foregoing, but we advise Mr. Smith and all other exhibitors *not* to "go in for the dirty work," not only because it is dishonest, but because sooner or later they are sure to be held up to public scorn.—EDS.]

INDUCING A HEN TO SIT.

IF "A SUBSCRIBER" or anyone, will take a *laying* hen—Brahma or Cochin to be preferred—and will place her in a sitting-box, only just large enough to hold her nest, into which have been previously placed half a dozen eggs, and will keep her very warm, she will soon show a desire to sit. Her food must be stimulating, and should consist of Indian corn, raw liver chopped, buckweat, hempseed, and a small portion of bread steeped in ale.—VINCENT FRASER.

[The above will be a reply to many querists. Many years since Mr. Holroyd, a druggist at Maldon, in Essex, had a hen that would sit until she hatched them whenever he placed her on a nest of eggs.—EDS.]

SILVER-SPANGLED HAMBURGHS.

"J. K. O." seems to think there is a great deal of difference between the Silver-spangled Hamburghs of the present day and those bred a few years since. We have been breeders of them eight or nine years and see none, only that cocks such as "J. K. O." has seen in his "Poultry Book" used to win, now they must be

well spangled all over, consequently they will be a little dark in the breast. Hens it is impossible to have distinctly marked if they have any of that green lustre that I think ought to be the first point in a hen.

"J. K. O." attacks the Crystal Palace prize birds. The first-prize pen contained an "unusually good hen" (see Journal). For large, clear, and distinct spangles, it would be hard for "J. K. O." to find her equal. The cock was well spangled all over, consequently rather dark in the breast, but not too dark to win at other shows besides the Crystal Palace. Perhaps "J. K. O." has bought a first-prize pen at some show, and been breeding from the birds. This any Hamburgh breeder knows will not do.—A. & B.

CRYSTAL PALACE BIRD SHOW.

The great Canary Show of the season is among the things that were, or it will be by the time this is in the hands of many readers of the Journal. For five months—from September to February—from Whitby (that gem of a Show) to the great Derby of the fancy, the monster gathering which is now in the last day of its existence, scarcely a week has passed without one or more exhibitions of a bird which, though supposed by many to be comparatively rare, is reared in the humble home of the artisan, and in the more pretentious establishments of the rich, by thousands.

The figures in the catalogue which, by the way, is a model for all large catalogues, show an entry of 954 birds for competition, and 152 in the Selling Class. Of these 566 are Canaries, 119 Mules, 34 groups of six, 5 miscellaneous, 118 British birds, 12 Migratory birds, and 100 Foreign specimens, including some very interesting and rare birds. It will be seen that numerically the Show is a great success, which is perhaps to be attributed in a great measure to some alteration in the classification. I submitted to the Superintendent what I thought was an improved schedule, that of previous years containing some inconsistencies, and a somewhat "Bridgenorth election," all-on-one-side, treatment of some varieties; an undue share of good things falling to some, and only a meagre allowance to others, which in point of value and intrinsic excellence were worthy of more liberal treatment. These defects I pointed out in detail in my review of last year's Show when the prize money was awarded on a principle not unlike that which report assigned to the distribution of prize money in the navy in days gone by, when it was said to have been sifted through a ladder, that which fell through going to the officers, the rest to the men. An equalisation of the scale has met with a willing response from the breeders of each variety. As I said before, numerically the Show is a great success. It always is, and must of necessity be so, as the number of "sold" tickets affixed to the cages shows what an additional inducement the opportunity of sale must be. Messrs. Judd, Mackley, Newmarch and Walter alone exhibit the enormous number of 333 amongst them; Mr. Newmarch heading the poll with 125, itself a little show. But as regards *quality* there is this year a deficiency. There are birds of exceptional beauty, as witness Mr. Walter's Clear Jonque and Mealy birds which were claimed at £5 each, and many of the prize-winners have great merit, but there is not that excellence running through the whole which in previous years has evoked a frequent comment from the Judges, but which on this occasion is appended to only about ten out of the seventy-six classes. My remarks thereon will appear next week. I am writing now under difficulties and in the excitement of the Show. Mr. Young reminds me I had better "finish Cheltenham first," but as many of the Cheltenham birds are on the stages here, and the Judges have confirmed most of my decisions, I may be able to kill two birds with one stone.—W. A. Blakston.

The British and Foreign birds were well represented, as also the miscellaneous. Amongst the former were some very rare birds, only a few specimens of them having been noted as having been found in England. Take for instance the Shore Lark, of which a very fine pair in good condition, the cock bird showing the peculiar horn-like appearance, were shown by Mr. Monk, of Lewes, in Sussex. There was a pair of Lapland Buntings sent by the same gentleman, all of which we understand were captured near Brighton. A fine specimen of the Crested Lark (Alaudus cristatus) was also present in perfect plumage. Naturalists know how scarce these varieties are, and how interesting it is to find them alive, and have the pleasure of noticing their habits and mode of life under confinement. Then, again, if these be scarce, how much more so some of the Mules. Take, for instance, that between the Blackbird and the Song Thrush, a bird possessing the characteristics of both; this was the first of the kind ever known; as also a cross between the Brambling and the Chaffinch. Then there were Mules between Goldfinch and Greenfinch, Linnet and Bullfinch, Goldfinch and Bullfinch, crosses unseen until of late years, and yet beautiful in themselves.

Some new classes were added this year, one of which was for Doves of any small breed, which brought a very beautiful pair of small Australian, but although prizes were offered for the Missel Thrush and Redwing, there was no response; but let us hope another season such may not be the case, but that the liberality of the Crystal Palace Company may meet with its reward in the way of more numerous entries, as, the more varied the collection, the more pleasing, and also the more educational it is to the public.

The show of Parrots was good, but nothing remarkable beyond other years. In the Miscellaneous pens might be mentioned a nearly White Blackbird, and several Pied Linnets,

Altogether there were 1327 entries, and nearly 1500 birds were present, as there were thirty-four aviaries which contained very many varieties, and shown in a highly creditable condition. Every care was taken of the specimens during the Show, and the healthiness of the birds reflects great credit on Mr. Wilson, the able Manager of the natural history department of the Crystal Palace.

Norwich (Clear Yellow).—1, W. Walter, Winchester. 2, Bemrose & Orme; Derby. Equal 3, Bemrose & Orme; Moore & Wynn, Northampton; Adams and Athersuch, Coventry. *vhc*, Toon & Cleaver, Kettering; R. Belgian (Clear and Ticked Yellow).—1, J. Rutter, Sunderland. 2 and 3, J. Hayes. Equal 3, J. Poole. *vhc*, J. Doel (2); J. Rutter (2). *hc*, J. Doel; G. & J. Mackley; J. N. Harrison. *c*, T. Dove; Wallace & Beloe.

Belgian (Clear and Ticked Buff).—1 and 3, Rutter. 2, J. N. Harrison. *vhc*, J. Doel; J. Poole; T. Dove. *hc*, J. Doel; G. & J. Mackley; J. Rutter.

Belgian (Variegated Yellow).—1 and 3, J. Rutter. 3, J. Hayes. *vhc*, T. Dove, Sutton-in-Ashfield.

Belgian (Variegated Buff).—1, J. Hayes. 2, T. Dove. 3, J. Poole.

London Fancy (Jonque).—1, W. Brodrick, Chudleigh. 2 and 3, T. Clark, Sutton, Surrey. *vhc*, S. Prince; J. Waller (3); C. Gayton. *hc*, R. Poole; Barwell and Golby; W. J. Marsbell, New Barnet; Moore & Wynn. *c*, Toon & Cleaver; J. Waller; Moore & Wynn.

Cinnamon (Buff).—1, Barwell & Golby. 2, Moore & Wynn. 3, J. Tear & Co., Wellingborough. *vhc*, A. B. Etherington; Toon & Cleaver; Wallace & Beloe. *hc*, G. R. Kennerley; R. Poole, Malden; Barwell & Golby; G. Cox. *c*, C. W. Hooke; J. Tear & Co.; H. Apted (2); Moore & Wynn.

Cinnamon (Marked or Variegated).—1 and 2, J. Taylor, Middlesborough. 3, W. Barnes. *vhc*, H. Stanley, Battersea; J. H. Hadland, Carshalton. *hc*, C. A. Stein, Peckham.

Canary (Any other variety).—1, W. Walter. 2, Wallace & Beloe. 3, Moore and Wynn. *vhc*, J. Spence, Sunderland; W. C. Selkirk, Dover (2); W. Walter. *hc*, R. Hawman; E. Stanfield, Bradford; Master J. Tennent, South Norwood; T. Newmarch & Sons. *c*, J. N. Harrison, Belper.

Goldfinch Mule (Evenly-marked Yellow).—1 and 2, J. Doel. 3, H. Ashton. *vhc*, J. Doel; H. Ashton; E. Stanfield. *c*, W. Barnes, Cannon Street, London.

Goldfinch Mule (Evenly-marked Buff).—1, J. Baxter. 2, E. Stanfield. 3, T. E. Jeffs. *vhc*, H. Ashton; W. C. Burniston, Middlesborough; J. Stephens, Middlesborough; W. Needler, Hull; W. Barnes. *hc*, J. Doel. *c*, Miss A. Inder, Guildford; T. Muldoon, London.

Goldfinch Mule (Any other variety of Yellow).—Special, H. Ashton. 1, 2, and 3, J. Doel. *vhc*, H. Ashton; E. Stanfield. *hc*, G. & J. Mackley; J. Baxter; E. W. Lulham.

Goldfinch Mule (Any other variety of Buff).—1, J. Doel. 2, H. Ashton. 3, T. E. Jeffs. *vhc*, J. Doel; E. W. Lulham. *hc*, J. Doel.

Goldfinch Mule (Dark Jonque).—1, J. Stephens. 2, J. Taylor. 3, E. Stanfield. *vhc*, R. Hawman, Middlesborough; T. E. Jeffs; Moore & Wynn; W. Mafield.

L. Chapman, Northampton. *hc*, J. Goode, Leicester. *c*, G. Cox; J. Jeffs. Northampton.

Goldfinch Mule (Dark Mealy).—1, Wallace & Beloe. 2, W. M. L. Chapman. 3, G. Cox. *vhc*, W. Holmes, Nottingham; Moore & Wynn. *c*, G. & J. Mackley; R. Hawman; G. Tuckwood; T. Moldoon.

Linnet Mule.—1, J. Spence. 2 and 3, J. Stevens. *hc*, W. Barnes; J. Judd.

Mules (Any other variety).—Prize, T. J. Monk, Lewes; S. Tomes; A. Skinner, Faversham. *vhc*, H. Ashton; W. Yeoman; E. Stanfield (2); W. Verner, Westbourne Park, London.

Six Norwich Canaries in One Cage.—1, Moore & Wynn. 2, T. E. Jeffs. Equal 3, G. & J. Mackley and Moore & Wynn. *vhc*, T. E. Jeffs; T. Fenn; W. Waller; T. Newmarch & Son. *hc*, T. E. Jeffs; W. Barnes.

Six Belgian Canaries in One Cage.—1, J. Rutter. 2, G. H. Nutt, Maidstone. 3, J. Doel.

Six Lizards in One Cage.—1, W. C. Selkirk. 2, J. Hayes. 3, Clark & Hooke. *vhc*, T. W. Fairbrass, Canterbury; Rev. V. Ward. *hc*, Clarke & Hooke; T. W. Fairbrass.

Six Goldfinch Mules in One Cage.—1, 2, and 3, J. Doel.

Miscellaneous.—Prize, J. Baxter (2); F. H. Gardiner.

Bullfinch.—Prize, J. N. Harrison. *hc*, G. & J. Mackley. *c*, O. Nicholaon; W. Waller.

Goldfinch.—Prize, Moore & Wynne. *hc*, T. Land; Moore & Wynne. *c*, J. Doel; J. Goode; J. Judd.

Linnet.—Prize, J. Judd. *hc*, J. N. Harrison. *c*, J. Spence; Miss M. A. Robinson, Sydenham; W. C. Barnston; A. Webster, jun.

Skylark.—Prize, J. Judd. *hc*, G. H. Nutt (2). *c*, J. S. Benton; G. H. Nutt. Woodlark.—Prize, W. Walter.

Robin.—Prize, G. Cox.

Blackbird.—Prize, G. & J. Mackley. *vhc*, E. Sweeting, Sydenham; D. Hunt. *c*, S. Harding.

Song Thrush.—Prize, W. Price. *hc*, N. Lowe, Norwood. *c*, W. Beckett, Gipsy Hill.

Starling.—Prize, G. H. Nutt. *hc*, T. B. Bailey. *c*, J. Judd.

Magpie.—Prize, G. & J. Mackley.

Jay.—Prize, Miss M. A. Robinson.

Any other Variety of British Birds.—Prize, T. J. Monk (Shore Larks); Rev. T. S. Carter (Avisers); J. Judd (Variegated Linnets and Snow Buntings); A. Skinner (Black and White Blackbird). *hc*, J. Young, Notting Hill (Aviary); E. Hodgkinson (Aviary); G. Cox (Yellowhammer); A. Webster, jun. (Bramble Finch); T. Newmarch & Sons (Pied Linnet and Snow Buntings, 2). *hc*, G. H. Nutt (Tree Sparrow). *c*, B. Verrall (Variegated Chaffinch).

BIRDS OF PASSAGE AND MIGRATORY BIRDS.

Blackcap.—Prize, L. Cossavella, Finsbury.

Nightingale.—Prize, G. Coram, Cambridge. *vhc*, G. Cox.

Siskin or Aberdevine.—Prize, G. & J. Mackley. *vhc*, A. Webster, jun.

Any other Variety.—Prize, W. Verner (Crested Lark); T. J. Monk (Lapland Buntinge).

FOREIGN BIRDS.

Cockatoo (Lemon or Orange-Crested).—1, M. George, London Docks.

Cockatoo (Leadheater or Rose-breasted).—1, T. Newmarch & Sons. 2, A. Vicars.

Any other Variety.—Prize, T. Newmarch & Sons (Slender-billed). *vhc*, Mrs. Drinsmire.

Parrots (Grey).—1, J. Cooley. 2, H. Jenner, Camberwell. *vhc*, J. Judd; T. Newmarch & Sons.

Parrots (Green or any variety of Large, except Grey).—1, Rev. A. W. Booker, Burford (Amazon). 2, J. Judd (Green). 3, W. Walter (Red). Extra, T. Newmarch & Sons (Mealy Rosella, Bulla Bulla, and Penunanter).

Parrots (King).—Prize, T. Newmarch & Sons. *c*, J. Judd.

Parakeets (Ring-necked).—Prize and *vhc*, T. Newmarch & Sons. *c*, S. Robinson, Sydenham.

Parakeets (Australian Broad-tail).—Prize, E. J. Oliver. *hc*, Mrs. Wood, Norwood.

Cockatoals.—Prize, T. Newmarch & Sons. *hc*, T. Newmarch & Sons; T. B. Bailey, Thirsk.

Parakeets (Australian Grass).—Prize, J. Judd. *hc*, Mrs. B. T. Walse, Brixton.

Doves (Barbary or Ring).—Prize, J. Lactchford, Norwood.

Doves (Small).—Prize, T. Newmarch & Sons (Australian).

Sparrows (Diamond).—Prize, Miss Rosher, Bedford Square, London. *vhc*, Master C. B. Budd, Peckham Rye. *c*, W. Walter.

Sparrows (Java).—Prize, T. Newmarch & Sons. *vhc*, Mrs B. T. Walshe.

Shells (Any variety).—Prize, J. Judd (Orange checked). *vhc*, T. Newmarch & Sons (Zebra). *hc*, T. Newmarch & Sons (Orange-checked); W. Walter (St. Helena). *c*, T. Newmarch & Sons (St. Helena).

Cardinal (Red-headed).—Prize, E. Sweeting.

Foreign Birds (Any other variety).—Prize, Miss Rosher (Madagascar Bird); Miss J. H. Price (Tame Japaoese Finch); L. Cossavella (Italian Solitary Thrush). *vhc*, Master C. B. Budd (Niger Mannskins). *hc*, Dr. Hosford, Stratford (Indian Mina or Mocking Bird); T. Newmarch & Sons (Bronze Mannakins); W. Walter (Pin-tail Nonpareil). *c*, T. Grey, Tottenham Court Road (Australian Piping Crow); T. Newmarch & Sons (Silver Beaks and Red-headed Macaw).

Judges.—*Canaries* : Messrs. Barnesby, Moore, and Willmore. *British and Foreign Birds* : Messrs. John Jenner Weir, F.L.S., and Harrison Weir, F.R.H.S., assisted by Mr. F. W. Wilson.

PORTSMOUTH POULTRY SHOW.

This was a very excellent show of both poultry and Pigeons. The arrangements, however, were certainly open to much improvement, the entries for the Selling classes having the most important and best-lighted position appointed to them, whilst the principal varieties were in many cases placed in situations in which it was difficult to see anything of their peculiarities. The placing plain boards directly upon the wire tops of the pens, whilst the only light was from the roof of the building, proved most objectionable, and appeared to have not a single redeeming feature. *Dorkings* were remarkably good, and the *Game* fowls, *Spanish*, *Cochins*, and *Brahmas* both Dark and Light, were exceedingly praiseworthy. A class for Andalusians brought no less than ten entries of capital fowls of this really useful breed. *Hamburghs* and *Polands* were well represented, and the classes of them extensive. In the Variety class Malays and White Spanish were the successful breeds. The Game *Bantams* were not so good a class in the eyes of visitors, as they actually were showing to great disadvantage, all the best pens being much exhausted by repeated exhibition.

Exceedingly large Selling classes comprised many most valuable pens, and consequently the number of lots claimed was unusually great.

Chinese Silver *Pheasants* were the only variety exhibited in the class for Pheasants. A very large entry of *Rabbits* and *Pigeons* completed one of the best Shows ever held in this neighbourhood.

Game (Black, and other Reds).—1, H. Gibson, Brockenhurst. 2, J. Jekin Eltham. 3, W. H. Stagg, Netheravon. *hc*, W. H. Stagg (2); H. Gibson.

Game (Any other variety).—1, E. Martin, St. Austell. 2, E. Wicwood, Worcester. 3, C. F. Terry, Tonge. *hc*, F. Pittis, Newport, Isle of Wight; A. Cosens, Arundel; J. Jekin; G. Potts, Chartham.

Cochins (Buff and Cinnamon).—1, H. Lloyd, jun., Handsworth. 2, S. R. Harris, Cusgarne. 3, Miss F. Milward, Newton St. Loe. *hc*, D. W. J. Thomas, Brecon; J. Sares, Pesford, Guildford. *c*, F. W. Rust, Hastings; J. Long, Plymouth; Mrs. C. F. Clay.

Cochins (Any other variety).—1, F. Brewer, Lontwithiel. 2, C. F. Wilson, Totton. 3, F. G. Coleridge, Henley. *c*, A. C. Travers, Falmouth; H. Yardley. Brahmas (Dark).—1, H. Dowsett, Fleshey, Chelmsford. 2, H. D. Dent, Cobham. 3, Rev. J. Ellis, Bracknell. *hc*, H. D. Dent; J. Chisman, Southampton. *c*, E. Martin.

Brahmas (Light).—1, H. M. Maynard, Holmewood, Isle of Wight. 2, H. Dowsett. 3, J. Sares. *hc*, Rev. N. J. Ridley, Newbury.

Brahmas (Light).—*Chickens*.—1, M. Leno, Markyate Street. 2 and 3, Mrs. A. Williamson, Leicester. *hc*, J. Pares; H. M. Maynard; J. Long. *c*, Rev. M. Rice, Steyning; Mrs. T. Turner, Avon; Mrs. Woolcombe, Lewdown; Mrs. H. Popham, Chasetcherch; M. Hall, Millbrook, Southampton; T. A. Dean, Marden, Hereford; J. Long.

Dorkings.—1, J. Chisman. 2, Rev. G. F. Hodson, North Petherton. 3, Lord Turner, Shillingslee Park. *hc*, W. S. Marsh, Winklands Oaks, Deal; Lord Turner; J. Shillingslee, Shillingslee Park.

Spanish.—1, Miss E. Brown, Chardleigh Green. 2, H. Brown, Putney Heath. 3, F. James, Peckham. *hc*, F. Pittis.

Andalusians.—1, W. Westcott, Landport. 2, T. Moore, Landport. 3, W. Wildey, Landport. *hc*, F. Pittis. *c*, J. C. Phair, Bedhampton.

Hamburghs (Golden-pencilled).—1, H. Moore, Weston-super-Mare. 2, F. Pittis. 3, G. W. Greenhill, Ashford. *hc*, W. Speakman, Nantwich. *c*, C. H. Mayo, Paddlestown; R. S. S. Woodgate, Feesbury, Tunbridge Wells.

Hamburghs (Silver-pencilled).—1 and 2, F. Pittis. 3, C. H. Mayo.

Hamburghs (Gold and Silver-spangled).—1, Miss E. Brown. 2, R. Wilkinson, Portsea. 3, R. H. Ashton, Mottram. *hc*, S. Newick, Hinton St. George; S. R. Harris. *c*, John Shillingslee Park, Ashford.

Polands.—1, J. Hinton, Warminster. 2, D. Mutton. 3, G. W. Boothby, Louth. *hc*, H. D. Dent, Cobham; D. Mutton.

French.—1, Rev. N. J. Ridley (La Fleche). 2, H. Wyndham, Rockhampton (Cuve-Cuns).

Any other Variety.—1, Rev. N. J. Ridley (Malays). 2, T. Norwood, Salisbury (Minorcas). *hc*, J. Hinton (Malays); R. Wilkinson (Minorcas); G. F. Hodson (Malay); C. Wilson (Hamburghs). *c*, S. R. Harris (Minorcas); W. Boots, Landport (Guinea Fowls); Ashford.

Game Bantams (Black and other Reds).—1, Rev. F. Cooper, Ampney Crucis. 2, W. Adams, Ipawich. 3, H. Gibson, Brockenhurst. *c*, J. Pares; F. Pittis; Bainton & Nicholson.

Game Bantams (Any other variety).—1, F. Fielder, Southsea. 2 and 3, Rev. F. Cooper. *hc*, Rev. F. Cooper; F. Pittis; J. Long. *c*, F. Pittis.

Bantams (Any variety except Game).—1, M. Leno. 2, R. Ashton. 3, H. M. Maynard. *hc*, J. Wilson, King's Heath, Birmingham. *c*, G. Hodson; M. Leno; H. Yardley, Birmingham.

Ducks (Aylesbury and Rouen).—1, F. Pittis. 2, J. Pares. *hc*, T. Hawken, Lostwi hiel; O. W. & H. Hoare, Brownlow.

Ducks (Any other variety).—1, T. E. Terry (Kasarka). 2, M. Leno (Mandarin). *hc*, R. S. S. Woodgate (Labrador); H. Brown (Carolina); T. E. Terry; M. Leno (Carolina).

Geese.—1, Mrs. Ford, Shirley. 2, J. Pares.

Turkeys.—1, T. Bailey, Landport. 2, Rev. N. J. Ridley. *hc*, C. E. Clay. *c*, J. Howard, Cosham.

Pheasants.—2, Mrs. Turner.

Selling Class.—1, W. Wildey, Cosham (Andalusians). 2, F. Pittis. 3, C. Wilson (Cochins). *hc*, J. Hinton (Malays); A. E. Smith, Gosport (Dorkings); H. M. Maynard (Hamburghs); H. Dent (Cochins); J. King, Oxford (Hamburghs); H. Dowsett (Brahmas); H. Brown (Spanish); J. Pares. *c*, W. W. Paine, Basing (Polands); D. Dunn, Hungerford (Dorkings); H. Dent (Cochin); M. Leno (Brahmas); F. Brewer.

Selling Class.—*Cock or Cockerel*.—1, J. N. Whitehead, Gnatton (Cochin). 2, J. King (Hamburgh). 3, H. Dowsett (Brahma). *hc*, D. W. Thomas, Brecon (Cochin); J. Sares, Guildford (Cuve-Cuet); T. E. Terry (Malay); G. W. Greenhill (Dorking); M. Leno (Brahma); F. Pittis; A. Cosens, Arundel (Game); A. E. Smith (Andalusians); G. Potts, Chartham. *c*, A. E. Smith (Dorking); O. W. & H. Hoare; F. W. Rust (Cochin); S. Newick.

Selling Class.—*Hen or Pullet*.—1, J. N. Whitehead (Cochin). 2, H. Brown. 3, J. Howard. *hc*, Lord Turner (Dorkings); W. Wescott; C. Pannell, Weybridge (Dorking); J. Pares (Duckwing); E. J. Reeves, Hayward's Heath (Brahma); H. Dent (Brahma); F. Fielder (Brahma); M. Leno (Dorking); F. Pittis; J. Moore (Andalusians); J. Howard. *c*, A. G. Rutherford, Tentworth, Midhurst; H. Dent (Cochin and Poland); F. Fielder (Game); M. Leno; H. Dowsett.

PIGEONS.

Pouters.—1, C. L. Gilbert, Salisbury. 2, Mrs. Ladd. *c*, G. H. Gregory, Taunton; W. Van Haansbergen, Newcastle.

Barbs.—1 and 2, H. M. Maynard. *hc*, H. Yardley; F. Fielder; W. Van Haansbergen.

Carriers.—1, H. Yardley. 2 and *c*, W. Quickfall, Shanklin. *hc*, C. L. Gilbert; F. Fielder; H. Jacobs, Sandown; W. Quickfall.

Dragoons.—1 and *vhc*, W. Bishop, Dorchester. 2, H. Allsopp, Birmingham. *hc*, C. L. Gilbert; Master Jacobs.

Tumblers.—1 and 2, Mrs. Ford. *hc*, H. Yardley.

Fantails.—1, Mrs. Ladd. 2, H. M. Maynard. *hc*, H. Yardley; H. M. Maynard.

Any other Variety.—1, F. Pittis (Jacobins). 2, C. L. Gilbert (Maltese). *hc*, C. L. Gilbert (English Owls); H. M. Maynard (Jacobins); F. Hodding, Salisbury (Turbits); W. Bishop (Persiana and Archangels); H. Yardley; W. Van Haansbergen.

Selling Class.—1 and 3, H. M. Maynard (Jacobins). 2, A. A. Vander Meerach. *hc*, F. Fielder (Antwerps and Turbits). *c*, O. E. Cresswell, Bagshot, Surrey (Fantails); F. Fielder (Dragoons); G. Gregory, Taunton (Owls).

CAGE BIRDS.

Norwich (Clear Yellow).—1 and 2, W. Walter, Winchester. *vhc*, T. Willsher, Chichester. *hc*, H. Apted, Broadwater. (2); *c*, & D. Carver, Landport.

Norwich (Clear Buff).—1 and 2, W. Walter. *hc*, H. Apted (2). *c*, C. & D. Carver.

Norwich (Evenly Marked or Yellow Variegated).—1 and *vhc*, W. Walter. *vhc*, M. Leno, and *c*, H. Apted.

Norwich (Evenly Marked or Buff Variegated).—1, *vhc*, and *c*, H. Apted. 2 and *hc*, W. Walter.

Belgian (Clear Yellow).—1, T. Moore, Fareham. 2, O. Nicholson. *vhc*, A. E. Smith, Gosport; O. Nicholson; T. Moore.

Belgian (Clear Buff).—1 and 2, A. E. Smith. *vhc*, O. Nicholson.

Belgian (Any other variety).—1, *vhc*, and *hc*, O. Nicholson. 2, T. Moore. *c*, C. Davies, Landport.

Lizards (Gold and Silver-spangled).—1, O. Nicholson. 2, L. Nunn, Southsea. *vhc*, O. Nicholson; A. E. Smith. *hc*, A. E. Smith. *c*, L. Nunn.

Goldfinch Mule.—1 and 2, R. Hawman, Middlesborough. *hc*, T. Willsher. *c*, L. Sparks, Landport; Bainton & Nicholson.

Canary or Mule (Any other variety).—1, O. Nicholson. 2, H. Apted. *vhc*, W Walter; H. Apted; T. Wilsher; C. Trower, Southsea. *hc*, O. Nicholson; L. Naun.

BRITISH BIRDS (Any other variety).—1, T. Willsher. 3, J. Harrison, Belper. *vhc*, J. Farlow, Southsea; W. Boots. *hc*, W. Smith. *c*, C. Trower.

FOREIGN BIRDS (Any variety).—1, J. Smart, Landport (Parrot). 2, C. Trower (Cockatoo). *vhc*, A. Van Senter, Southampton (Portuguese Lark); W. Walker (Spice Bird and Parrot). *hc*, G. Stanfield (Rosellas); G. Wilkinson (Paroquet). *c*, G. Stanfield (Rock Parrot).

RABBITS.

LENGTH OF EAR.—1, W. H. Webb, Coseley. 2, T. E. Terry, Tong, Leeds. *c*, A. H. Easten, Hull.

BLACK AND WHITE AND BLUE AND WHITE.—1, King & Quick, St. John's Wood. 2, F. Loveland, Lisson Grove, London. *hc*, J. Grant, Landport; T. E. Terry; King & Quick; A. L. Pearce, Doncaster; A. Easten.

GREY AND WHITE AND YELLOW AND WHITE.—1, W. H. Webb, Bilston, Stafford. 2, T. E. Terry. *vhc*, E. Cantelo, Newport; T. E. Terry; King & Quick; A. H. Easten.

TORTOISESHELL.—1, T. E. Terry. 2, H. C. Perrin, Brighton. *hc*, A. H. Easten; King & Quick.

SELF-COLOUR.—1, H. Cawood, Thorne. 2, A. H. Easten. *hc*, W. Webb; T. E. Terry. *c* E. Cantelo.

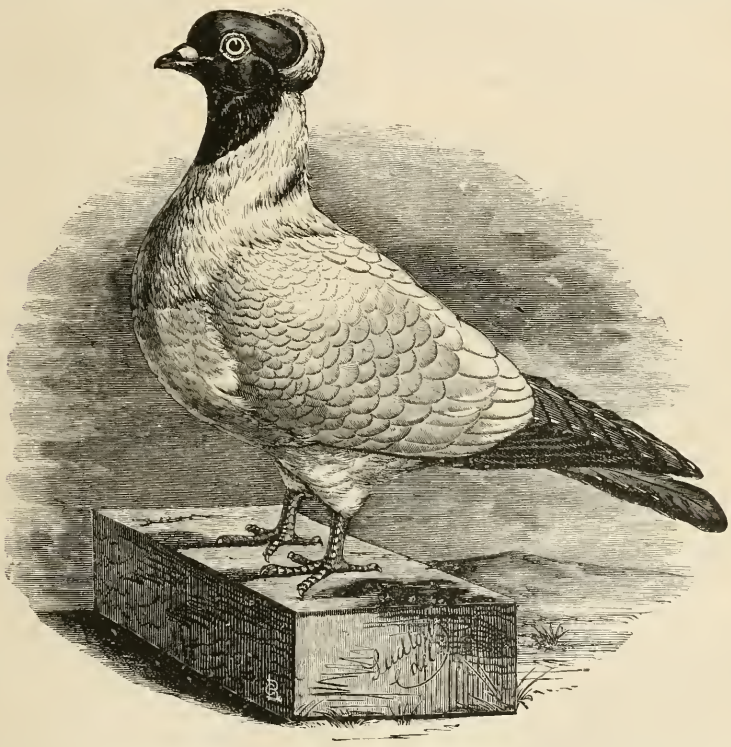
ANY FOREIGN VARIETY.—1 and 2, T. E. Terry. *vhc*, T. E. Terry; A. Pearce. *hc*, T. E. Terry (2); A. H. Easten; A. Philips, Oaklands, Waterloo. *c*, A. Clayton, Ryde.

WINNERS OF CUPS.—For most Points in Poultry, Mr. Pittis; for Brahma Chickens, Mr. Leno; for Brahma Adults, Mr. H. M. Maynard; for Andalusians, Mr. Westcott. For the most Points in Pigeons, Mr. H. M. Maynard; for the most Points in Norwich Canaries, Mr. Walter; for the most Points in Belgian, Mr. Nicholson; for the best Belgian, Mr. T. Moore; for the most Points in Rabbits, Mr. Terry.

JUDGES.—*Poultry:* Mr. Edward Hewitt, and Mr. W. B. Tegetmeier. *Pigeons:* Mr. F. C. Esquilant. *Cage Birds:* Mr. A. Willmore. *Rabbits:* Mr. E. Owen.

THE NUN PIGEON.

THIS variety is a general favourite among the Toy fanciers, and on account of its hardiness and docility it is particularly suitable for the novice. It soon accommodates itself to its surroundings, breeds well, and seldom fails to rear its offspring;



consequently Nuns are very useful for nurses, but when they are highly bred they are not so reliable in this capacity.

The chief attraction in a Nun is usually considered to be the perfectness of its markings, and a too-close attention to this has prevented their being bred to a high standard in other points, which adds so much to their beauty. The result of breeding for feather only, has more particularly caused the breed to deteriorate in form and carriage, and to become coarse and large.

The Nun should be very merry, small, and neat—very little larger than a Tumbler. The shape should be elegant, and the carriage sprightly. Whatever the colour, it should be deep and rich, with the tail of one uniform shade and of equal depth and richness as the head. In all Nuns the feathers of the head, veil, flights, and tail, with the upper and under tail coverts, should be of one colour, and those of the remainder of the bird perfectly white.

The black-headed variety is the most numerous; probably because it is the most striking and pleasing in contrast with the white body. The beak ought to be small and jet black, without any shade of ashy greyness about the nostrils or beak-wattle. The head should be small and round, rising with tolerable boldness from the beak; the irides of the eyes ought to be pearl white, and the eyelids forming ceres, or white fleshy circles, around the eyes. A gravel eye is inadmissible in a good Nun, and feathers overhanging the upper eyelid are a serious fault. In the high-bred birds the feathers of the hood are perpendicular, and do not form a cap over the head. A well-defined hood is a most important point; it should be large and the top square, it should also be as thin as possible, to be

of a perfect form, so that the loss of a single feather would break the evenness and show the deficiency. The less lined with the coloured feathers the hood is, the more admired. The veil or upper part of the throat should be of the colour of the head, and should extend well backward to the side of it, but not behind it; the veil should also be quite even on each side of the throat, of good round form, and should not extend too far down. The head should be thrown back, and the neck be small, and gracefully enlarging until it be lost in a full breast.

There should be from eight to ten coloured flight feathers in each wing, but ten we consider the best, as it causes a more evenly cut line than any other number, and when the two wings are brought together upon the back, they form a most perfect saddle. The upper and under tail coverts should also be as even as possible. The legs should be clean, and of a bright red colour, which contrasts so well with the white thighs. The claws should be black.

When the specimen is black, the whole of that colour should be deep, glossy, and intense, and the flight and tail feathers free from a bronze, blue, or mousey appearance.

As the size of a Nun is such a material point we may say that the weight of a good specimen should not exceed 10 ozs. when in high condition.—Birmingham Columbarian Society—J. W. Ludlow, *Secretary*.

WHITEHAVEN POULTRY SHOW.

The Show held in the Riding School, Whitehaven, last week was very successful, and the improvements made by the Committee in the general arrangements deserve especial mention, for on no previous occasion has the light been so generally good, nor the space for the accommodation of visitors so ample, although the entries at this year's meeting exceeded those of last season by nearly a hundred pens.

A striking portion of the Show was the entry of White *Cochins*, and we speak advisedly when we say that never before in this kingdom has so good and numerous a display of this valuable breed been witnessed. These birds were mostly shown in truly exquisite condition, and they were of much larger size and more marked character than usual. The Buff Cochins were remarkably good and extensive entries, though some of them were quite overshown, and the Partridge-feathered, though few in number, were really good. In Dark *Brahmas* the hens showed to somewhat greater advantage than the cocks, as they evidently endure continuous exhibition much better than their male companions. Strange to say, throughout the whole Exhibition not a single pen of Light Brahmas was entered, not even in the Selling class. There was a very grand display of *Dorkings*, including the most choice specimens from Messrs. Lionel Patton, Holt, and Dickenson. The Silver-Grey Dorkings proved also exceedingly good, and were, therefore, a strong and superior class at Whitehaven. *Spanish* were most excellent, and Mr. Charles Brierley secured the silver cup for this breed with a truly grand pen. The *Game* classes were not only very superior, but most of the birds were shown in extraordinary condition. The principal winners in this division were Messrs. James Fletcher, William Barnes, H. Julian, and E. Ackroyd. In the Extra Variety class Golden and Silver-spangled Polands were first and third, and Black Hamburghs took the second prizes.

Game *Bantams*, though very extensive classes, were mostly quite out of show trim, from having been almost continuously of late in the exhibition pen; the prizetakers were admirable specimens. The Selling class, from the fact of an excellent sewing machine being offered as the first of five prizes, was remarkably large, nor can we call to mind any class of the same description proving so generally good from end to end, the fact being scarcely a pen of inferior birds of any kind could be pointed out. The pen of Black Spanish that were the winners of the sewing machine were evidently well worth seven or eight times the restricted price that is usually the limit of Selling classes; but as by a prudent regulation of the Committee all the birds in the Selling classes were to be sold under the hammer on the second day of the Show, the excess, if any, beyond the entry price, if sold, having to be equally divided between the Society and the exhibitor, no collusion in "claiming" by the owners could be put in practice, and as a great number of pens of very high value would thus be offered, no doubt a very spirited and remunerative result would ensue. We have not, however, heard any particulars of the sums realised, but consider this regulation to be one that has long been needed at the majority of shows in the Selling classes.

Geese and *Turkeys* mustered only six pens in the classes combined, but all six were superior exhibits.

We have purposely left the mention of the *Hamburgh* classes to the last, having, as faithful journalists, to allude to no less than three discovered instances of "trimming" in this division of the Show alone, one of these, at least, being, we are sorry to say, of the most heartless and cruel character that can well be imagined. We must preface our remarks by saying only seldom have the classes for Hamburghs contained so many perfect birds as those on view at Whitehaven. There being a distinct rule against the "clipping" of plumage and "trimming" generally, the Committee very properly withheld in all three of these instances the ill-gotten positions previously granted to the respective pens, and we cannot but express a most hearty wish that the open exposure of the names and practices resorted on this occasion may prove, at least for a time, some little deterrent to actions so grossly cruel and palpably dishonourable.

As these were very serious charges, it was quite requisite they should be supported by the strongest evidence, and our readers will look with grave anxiety to the mode adopted to ascertain the truth of the accusations. To this end a full meeting of the Committee was called for an early hour on Friday morning, the 9th instant, and although, unfortunately, Mr. Teebay had been compelled to return home on the previous afternoon, having been summoned to give evidence in a court of justice, Mr. Hewitt was luckily still on the spot, and the examination of the pens in dispute was openly carried out in the presence not only of all these gentlemen, but also of a few of the principal exhibitors, so that not a single doubt could be entertained by anyone as to the facts about to be stated. We will first allude to pen 216, being the pen of Golden-spangled Hamburghs to which the silver cup for the best pen of Hamburghs was awarded, exhibited by Mr. John Rollinson, of Lindley, near Otley, Yorkshire, in which the plumage of the hen had been most cleverly "clipped" to take away the white tips to the general plumage, with which no small portion of her feathers had been "flecked." On taking her into a good light it was obvious that a great portion of her feathers had been tampered with, though it must be admitted it was scarcely visible in a moderately dark pen. One feather was carefully drawn from the back, and another from the breast of the hen that had been the least cleverly manipulated, and these feathers were permanently taken into the possession of the Committee as standing proofs; nor must it be imagined these were the only two, as scores of feathers more or less dexterously "clipped" still remained, and could have been produced, if wanted, in confirmation of the extent of the deception that had been practised.

The case next in order was pen 239, Silver-pencilled Hamburghs. In this instance a considerable portion of the sickle feathers of the cock were dyed black. This pen was exhibited by Mr. David Lord, of Daisy Cottage, Stacksteads. By means of a chemical appliance the colour was discharged in those portions of the feathers that had been operated upon, whilst no change whatever took place in such parts of the same feathers as were naturally black. The Committee, and, in fact, every bystander, could only express their thorough conviction, but as the bird would have been injured by the extraction of the sickle feathers, it was returned to the pen without the withdrawing of a single feather.

The last case was, beyond question, not only a gross attempt at deception, but one of such unpardonable torture to the bird operated upon, as to urgently demand the interference of the Society for the Prevention of Cruelty to Animals. This pen stood in the catalogue as 230, Golden-pencilled Hamburghs, the property of Mr. Joseph Walker, of Bristwith, Ripley, Yorkshire. It was noticed that the cock in this pen threw its head about in a very distressed and unusual manner, and that at intervals it raised its foot, apparently with the intention of touching its comb, but every successful effort seemed to produce great suffering. On taking this cock to a strong light, not only could it be perceived that the comb was evidently inflamed, but also that the extreme point of a pin or needle projected over the nostrils. It was most firmly embedded, and would not draw through even with tweezers, but was at last, after some considerable pulling, extracted by the opening at which it had been forced through the whole of the comb. It now proved to be a strong pin, with the head still perfect, but the shank somewhat cankered, a circumstance which no doubt increased not only the difficulty of extraction, but also produced the inflammatory symptoms before noticed. This poor bird was returned to its pen evidently much relieved, but the pin is still in the safe keeping of the Committee. By the conclusive means used for conviction the Committee were perfectly satisfied, and the respective owners lost a silver cup, a second prize, and a high commendation.

In the *Pigeon* department Mr. Ord's pen of well-known Dun Carriers were the winners of the silver medal for the best pen of Pigeons in the Show. Perhaps a greater novelty in Pigeons has not been seen for years past than a pair of quite a new variety, sent by Mr. A. Prosche, of 6, Fagdiveg, Dresden, at a carriage expense alone of over 16s. to their owner, quite irrespective of the entry fee, and which, from their singularity, were, at the suggestion of the Judges, awarded an extra first prize. These strange Pigeons had much of the general character of small foreign Blue Owls, being perfectly frilled on the crop, whilst immediately under the throat was a well-defined semicircle of feathers turned *upwards*, the points extending to behind the

ears, somewhat suggestive of the cowl of a Jacobin Pigeon inverted, or placed under the head and before it, in lieu of the customary position at the nape of the neck and upright.

Teebay, Fulwood, Preston. Pigeons: Messrs. E. Hewitt & R. Teebay. Canaries: Mr. A. Benson, Whitehaven.

PIGEONS GOING LIGHT.

I TRUST a few remarks, founded on facts that came under my notice during the examination of upwards of twenty birds from various lofts, may be acceptable to your readers. It is not my intention to trespass on your space by giving particulars of the various experiments made, but simply to state it is my belief that worms are in most cases the cause of so many valuable birds wasting and dying, also that the malady is contagious. A short time since I went to see the stock of an old fancier—crouched in a pen was a good-bred Tumbler in the last stage of the so-called consumption. I told the owner what the bird was suffering from; he laughed at the idea. The bird was examined after death to convince him, and it contained upwards of one hundred worms, some 2 inches in length.—J. PHILPOTT.

ALLOW me to state in reply to Mr. H. Allsop's very useful hints, that I always use cod-liver oil for my Pigeons when going light. It is done up in "capsules," which prevent the feathers becoming greased. The birds take the capsules very easily; they are to be procured at any London chemist's for a halfpenny each, or 1*s.* per box of thirty-six. Castor-oil capsules are also to be procured, and at the same price. They should be put in cold water for about half a minute before giving them to the birds; being rather large they slip down better that way. One is quite enough for a dose, two in extreme cases.—A. MEERSCH.

BIRMINGHAM POULTRY SHOW.—The annual meeting to revise the prize lists for the present year is fixed for Thursday, 22nd inst. The Secretary will be happy to receive and place before the Council any suggestions for improvements, or any offers of special prizes either in the cattle, root, or poultry department. The direction to the Secretary is Mr. John B. Lythall, 39, New Street, Birmingham.

LARGE VERSUS SMALL HIVES.

I SHOULD like to call the attention of subscribers who have read the interesting articles on this topic by "CAROLUS" (page 479, vol. xx.), and "J. LOWE" (page 520), to a suggestion of mine in vol. xviii., page 237, headed "Dummy Frames."

I think my plan would suit all parties; they could have hives of large or small capacities at will, according to the season or locality. Your opinion was, that the whole ten combs were required for breeding purposes, but my experience of ten Woodbury hives during three seasons does not correspond; I have never found combs 1 and 10 containing brood.

I had an excellent opportunity of testing the fact this summer. Most of my strong supered stocks swarmed—some more than once; and when cutting out the queen cells before re-placing the swarms, I particularly noticed that the two outside combs were not being used for breeding, but most of them were quite filled with sealed honey. I thus lost a quantity of honey which I could have sold for 1*s.* 6*d.* per lb., and have replaced with syrup at a cost of 3*d.* per lb., and at the same time profited by the advantages pointed out in the article. Last winter I lost three of my best stocks during that long frost through starvation; although each had nearly 12 lbs. of honey left in the side combs, that in the centre ones had been all consumed.

If I had carried out my plan the autumn-given syrup would have been deposited in the middle combs, and my stock have been saved. I should much esteem your reconsideration of this matter, and Mr. Lowe and "B. & W." perhaps would also favour me with their opinion.

The question is, Would the bees in a supered colony prefer to breed or to store honey in the end combs of the stock hive?

I should like to mention a curious incident that happened to me last season. I had in my apiary a colony of black bees, the queen of which had been killed for the purpose of adding a Ligurian that I had bred in a nucleus; upon opening it to take her out I found the bees ill-treating her. I dispersed them, and was about to take hold of her when she suddenly took wing, and I had the mortification of seeing my queen, after making a few circles in the air, fly clean away. I closed the nucleus and watched till dark, but saw nothing more of her. Judge, then, of my surprise when, upon opening my black stock the next afternoon, I found my queen comfortably settled in the very hive I had intended to join her to! Although there were ten others all in a row, she had selected the only one of the number that had no queen. Accident or sagacity, do you think?—THE BEE-HIVE.

OUR LETTER BOX.

BOOKS (*A. Atkins*).—Eaton's volume is out of print.

FRENCH AND GERMAN PERIODICALS (*M. Henderson*).—We know of none such as you mention.

DUNDEE POULTRY SHOW.—The address of Mr. J. Stuart, who won the first prize and cup for Brahma chickens, is Thistlebank, Helensburgh, not Scourlingburn, as printed last week.

DUBLIN PIGEON SHOW (*Reporter*).—We cannot admit replies to the statements in a contemporary. (*N. B. C. S.*).—The name cannot be given, nor can we insert any more notes on the subject.

PROMOTING LAYING (*J. S.*).—Your communication confirms us in our old opinion, that good moderate feeding is all that is necessary for laying fowls. The green food has much to do with it. We are very infants in the use of it compared with our neighbours on the Continent. We grow backward turnips on purpose to give the greens to our poultry and Pheasants, and they like it in preference to anything.

ROOSTS FOR BRAHMAS (*A. B. G.*).—Our Brahma perches are made of firpoles 14 inches in diameter, sawn in half, and fastened the round side uppermost. They are 20 inches from the ground. Most of the fowls roost on them, but some prefer the ground, and to prevent that we place some old roots of trees in the house. The only objection to these last is, they take considerable time to clean every morning. The birds prefer perches with the bark on them.

MOVING A BROODY HEN (*F. T. W.*).—There is always difficulty in moving a broody hen unless much care is taken. She should be moved in a very low dark basket with plenty of soft straw, that she may keep very warm. Put her in a low basket with 4 or 5 inches of soft straw under her, place her on some false eggs, and tie her down. Put her in a dark place. If she intends to sit, she will when the basket is opened give unmistakeable tokens by grunting and growling; if she does not, she will at once fly out and leave her eggs. If she shows a disposition to sit close, leave her on the dumb eggs (worthless ones if you have no artificial ones) for a day or two, and then put good eggs under her, but she must be always tied-in.

ADDLED EGGS (*Grausendale*).—The cock being with the hens a week before the eggs were saved for sitting was long enough, but at the season of the year when the eggs were laid cocks are not attentive to all the hens, especially if the latter are numerous, and those you mention were certainly not impregnated. The Andalusians are quite distinct from the Minorcas. A slaty blue, with dark hackle in the cocks, is their colour. They are not uncommon.

WOUNDED COMB (*G. L. P.*).—If you intend to exhibit the bird you must not interfere with his comb, except to heal it, but you must keep it upright, which may be done with straps of adhesive plaister. If you have no intention of exhibiting you may remove the piece that hangs down, but we should try to save it.

BRAHMA HEN'S ABDOMEN SWOLLEN (*J. W. T.*).—Your poultry diet will make the fowls fat, and induce constipation, especially as you do not mention green food. Very often the appearance you mention is caused by hard fæcal matter. Cut away the feathers to which it adheres, or soften them with hot water, and give her a dessert-spoonful of castor oil. If it be a tumour on the outside the hen's body, it can be easily removed if it be an ordinary one. Make a cruciform opening the size of the tumour, and press it at the base, a round hard cheesy substance will be expelled. Wash the wound with warm water, draw the lips of the wound together with a thread, and rub some spermaceti ointment on it. It will soon heal. Discontinue the potatoes and pollard and the wheat. Give plenty of green meat, and some large sods of growing grass, cut with plenty of earth to them.

DUCK EGG ABNORMAL (*J. N.*).—The egg you mention, weighing 6¼ ozs., with a perfect egg within it, is a curiosity. The double-yolked egg laid afterwards is proof that for the time the laying organs are out of order.

FEATHER-EATING BRAHMAS (*S. S.*).—Some breeds are addicted to the abominable practice you complain of, but we have never found it in Brahmas. Discontinue the beer and the kitchen scraps. On the days of confinement give green food plentifully, and watch for the worst offender; remove him or her. You will be unable to stop it while the bare spots remain, especially if they are raw; and as Brahmas do not suffer from confinement, we advise you to take all the birds that have suffered and shut them up singly till the feathers are grown. They have done it for lack of something, and in a short time they will forget it.

DARK AND LIGHT BRAHMAS (*Alwirdus*).—We are not aware of any difference in the laying of Light and Dark Brahmas, or in the size of the eggs. We believe some of the imported Light Brahmas are heavier than the Dark ones we see commonly. We cannot do better than refer you to our advertising columns, advising you to choose from the names that are most commonly found among the successful exhibitors in the classes you mention.

BRAHMA STOCK (*Just Commencing*).—There is no objection to your Brahma cock having a speckled breast. The best birds we ever had had them. The vulture-hocked hen is a much more serious matter, and there is every probability her chicks will have the same fault. She would, probably, be disqualified in competition with others not vulture-hocked.

BARNS AT WOLVERHAMPTON.—"*Curious*" wishes to know to whom the first-prize pen belonged.

CANARIES (*R. F.*).—Write to W. A. Blakston, Esq., 22, Norfolk Street, Sunderland.

PRAIRIE BIRDS (*A Constant Reader*).—We believe the idea that they are sometimes poisonous on account of a herb they have eaten, is totally groundless.

LIME WATER (*Three-months Subscriber*).—It is not poisonous. If it were, we should have said so, as we did of the corrosive sublimate.

MILKING MACHINE (*Hampshire*).—We know of no one who uses any other machine than the dairyman's or dairymaid's hand.

REMARKS.

7th.—Bright and dry in the morning, and so continued till after 5 P.M.; at 6.45 rain commenced, and was followed by a wet evening.

8th.—Rather damp morning, but beautiful day, dry and warm with fine sunset, though rather hazy afterwards.

9th.—A very fine day, dry, bright, and warm.

10th.—Fine all day, pleasant air, and starlit night.

11th.—Rather dull in morning, fair all day, but not quite as bright as the preceding day.

12th.—Fine morning, but getting more and more dull after noon; rain between 7 and 8 P.M., which continued for some time.

13th.—Dull in early morning, but clearing off before 9 A.M., bright sunny day, but rather cold; rain after midnight.

With generally finer weather, the range of temperature has naturally considerably exceeded that of previous weeks; the mean range in shade has increased from 8.9° to 14.0°, and that of the exposed thermometers from 23.6° to 41.6°.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 14.

A STEADY regular demand has characterised the transactions of the week, and a continuous supply enables all parties to be served. Continental supplies are well kept up and are very useful; from the Azores there has been a good freight of Pines again, and some good Bananas. Hothouse Grapes comprise Gros Guillaume, Black Hamburgh, Lady Downe's, and Trebbiano, the latter, however, not first-rate, and unsaleable from its brown colour. First-class Regent Potatoes obtain a better price; in all other kinds the trade is heavy.

From observations taken near London during forty-three years, the average day temperature of the week is 47.6°; and its night temperature 32.7°. The greatest heat was 62°, on the 25th, 1868; and the lowest cold 18°, on the 24th, 1860. The greatest fall of rain was 0.92 inch.

NOTES UPON FERNS.—No. 1.

OUR correspondent "Pteris" has, in a letter to us upon Fern-culture for amateurs, opened up a very wide subject. His remarks in it are good, and the subject is a popular one; but to carry out what he wishes would take up immense space; indeed, the subject is so vast that a volume might be written upon it without exhausting it. Briefly, however, as the details of the various parts of these plants must of necessity be treated upon in the pages of a Journal like ours, I shall, nevertheless, endeavour to deal with the subject so that the amateur may take up the study and prosecute it, even in a strictly scientific manner, should there be occasion for so doing.

I may state here, to prevent my being suspected of plagiarism, that many of the ideas and descriptions will be found to coincide—nay, may even be couched in very similar terms to those of Mr. J. Smith in his various writings upon Ferns. But as I acquired my knowledge of these elegant plants under the tuition of that eminent pteridologist, and had the pleasure of assisting him to some extent in his last work upon Ferns,* and am a staunch believer in his views, it will be readily understood why there is a similarity. I consider the characters obtained from habit of growth, in conjunction with the venation and the disposition of the sori, as more likely to lead to just conclusions for purposes of classification than it is possible for anyone to obtain by adopting only one of these organs as a guide. A study of the living plant, in my estimation, is of vast importance in determining both generic and specific distinctions. It is the custom of some of our eminent living botanists to speak slightingly of those who do not confine their studies to herbarium specimens, calling them mere garden botanists; but I am aware of several cases in which those systematic botanists who believe only in dried specimens would have committed grievous errors, and published them to the world too, if they had not been put right by "mere garden botanists." Do not think that I depreciate herbarium specimens; on the contrary, I value them highly, but I consider they should be used conjointly with living plants upon all possible occasions.

To resume my subject, however, it is necessary to come back to the Ferns, of some of which none of my readers will be entirely ignorant. The immense number of new species which have been introduced to Europe during the past thirty years is sufficient evidence of the general favour in which these plants are held. Popular as they have become, our correspondent "Pteris" assures us that there yet remains amongst amateurs a great lack of knowledge of their general structure, their various organs, and the relation of these organs to each other, as well as of the wants and treatment of the plants. It is to supply this want, therefore, that these lines are written.

If a knowledge of the name and native habitat of any plant, together with its medicinal or economic properties, fail not to give it additional interest in the sight of the owner, how much, then, must that interest be increased when the peculiarity of each particular organ is well understood? What a great assistance this is also to amateur cultivators who have not the command of plant houses of varied temperatures, in enabling them to experimentalise with their pets until the proper situation is found to suit their requirements. That this knowledge is not absolutely necessary I admit, for I have known several men who, without being acquainted with either the name or native country, have yet been skilful cultivators, yet the fact that their success would have been more sure, and the results more rapidly secured, had the natural surroundings of any strange plant been familiar to them, cannot be denied. Many amateurs shrink from the study of the natural history of their plants, from the supposition that the technical phrases are difficult to acquire and understand. This, however, is rather an imaginary than a real difficulty, as I have frequently found the very person who complains most of the hard terms employed by botanists converses most glibly upon the beauty of Hyacinths, Camellias, Fuchsias, Geraniums, and Dahlias, entirely forgetting that these are foreign words which have become naturalised by frequent use. Though I do not contend that pure systematic botany is essential to a good education, or likely to interest or be of great service to the public generally, yet a knowledge of the properties and organs of plants, which may be designated "domestic botany," tends to give much pure enjoyment, elevates the mind, and enables us all better to fulfil our duties in life.

With these preliminary remarks I shall leave the generalities, and confine my remarks specially to the subject of Ferns, of which our correspondent "Pteris" desires to obtain for himself and friends some information.—Experto Crede.

* Ferns, British and Foreign, by John Smith. London: Hardwicke.

CULTURE OF THE IXORA.

In many respects none of our stove plants surpasses or even equals the Ixora. When properly managed it is rarely without a few trusses of bloom, whatever the time of year. It is of easy culture where the necessary conveniences exist, and will amply repay any attention it may receive. It is rarely we see well-grown specimens of these beautiful plants amongst amateurs, though some of our well-known exhibitors show them in perfection; but taking amateurs generally, the plant is almost unknown to many of them. And why is it so? The same old tale: "I bought a plant and have lost it; I will not buy another, we cannot grow it." These are expressions I have often heard used in speaking of many of our beautiful and free-growing stove and other plants, and yet failure in their culture is not the fault of the plants but of the grower.

The Ixora is of easy culture, provided there is a proper house to grow it in; if such does not exist it is useless to make the attempt; but give it a little careful attention, together with a well-heated house, and I know of no other plant that will afford more satisfaction. Perhaps a few

hints will be acceptable to some who have hitherto been unsuccessful.

Ixoras are evergreen flowering shrubs, and therefore do not require to be dried-off in winter or to be allowed a period of rest. They delight in a moist warm atmosphere, and in abundance of bright sunshine; in fact, exposing the plant to the rays of the sun is highly necessary, in order that the growth may be matured and the buds set. The Ixoras will grow and bloom profusely in winter, as well as in summer, although it is not advisable to force them much in winter, especially if they are required for exhibition. If, however, they are kept in a moist and warm atmosphere they will produce a quantity of bloom, which is very cheering in the dreary months of winter, and whether flowering in the summer or winter, their beautiful trusses are always acceptable.

Before proceeding further I would again say, Do not attempt to cultivate Ixoras unless you have a stove or hot-water pit where they can have plenty of heat and atmospheric moisture, and where you can apply the syringe freely. I know of no other plant that delights more in being freely and often syringed, and frequent syringing will prevent the occurrence of those enemies by which the Ixoras are most liable to be attacked—viz., mealy bug, green fly, and brown scale. I do not believe any blight-composition is so effective as clean water, a syringe, and a heart to use it. The neglect of these has caused the untimely end of many a beautiful plant, and I cannot impress too strongly on the minds of amateurs and gardeners the necessity of frequently using the syringe and clean water. If they did so they would not require half the blight-compositions that are now prepared, many of which injure the plants more than the insects.

Let us now suppose we have just purchased a healthy young plant of an Ixora free from insects, and in a thriving state. Give directions to the person you purchase it from that it shall be warmly and securely packed, so that it may not be injured in transport. When it arrives place it in the stove, say in a temperature of 65° to 75°, and see that it is regularly watered and syringed with water of the same temperature as the house. It is essential—to say nothing of the convenience—to have a tank in every stove, so that the water used both in syringing and watering may be of the same temperature as the house. In a week or two the plant, if all go well, will begin to show signs of fresh growth, and should, consequently, be examined to see whether it requires shifting into a larger pot. If such is necessary prepare the soil for potting. I have found the best mixture to be equal parts of fresh turfy peat and half-decayed turfy yellow loam, with a free admixture of sharp silver sand, adding a few lumps of charcoal about the size of a walnut.

Prepare the pot, placing three or four large crocks at the bottom, then fill to a fourth part of the pot's depth with smaller crocks, and place a layer of the roughest of the soil over these. Turn the plant out of its pot, remove all the old crocks from the bottom of the ball, and if the roots are matted round the ball loosen them very carefully, so that you will thus in some degree break the ball, for if this were left unbroken the plant might suffer in consequence of the water being unable to pass through it. Place the plant in the middle of the pot, and in such a position that the old ball will be about an inch below the rim; fill-in all round with the compost, give the pot a few smart taps on the potting-board, and if the plant is a good-sized specimen use a rammer in the shape of a thick stick a foot long, so that the soil may be firmly and evenly pressed-in. Finish-off the top neatly and evenly. All being now completed, replace the plant in the stove; and if the foregoing hints are attended to I have every reason to think that success will be certain.

I may add that for established plants I have often found a little manure water very beneficial, and, when I can obtain them, I use cow-droppings diluted in water, and used in a clear state not more than once a-week.—T. B.

FORCING VEGETABLES.—No. 6.

RHUBARB, SEA-KALE, AND MUSHROOMS.

As the two first-named vegetables have been so often treated of by Mr. Fish and other writers at different times, I feel that it is unnecessary for me to go into the details of their treatment. I may, however, mention that although both Sea-kale and Rhubarb are very successfully forced in more ways than one, I still advise the old plan of forcing in the open ground as being the best both for produce and flavour. In that way there is no mutilation of the roots, nor are the plants checked or robbed of any of their stored-up juices; and if gradually forced with a mild heat, as such vegetables always should be, they will continue to produce a good second, and even a third crop, without damaging to any great extent their power of producing a successful one by forcing again the following year.

But where there is a scarcity of heating material, such as dung and leaves, then the plan of taking up the roots and forcing them in any artificially heated structure may be resorted to with good success. In making-up my out-door beds I avoid using the manure too fresh, and if possible I mix half leaves with it to prevent the produce from tasting of the manure. In the case of Rhubarb and Asparagus I find that which is sent to table unblanched is much preferred to that which is sent blanched, and is said to be of a much better flavour. This I do not doubt, and it is certainly better in appearance when it has a more natural colour. To very many growers, however, economy in space and also in forcing is absolutely necessary. To such the method of taking up the roots and forcing them in close quarters is commendable, the way of doing which may be found in some of the back numbers of this Journal.

Coming now to Mushroom-growing, we have a more delicate and important subject, of which I purpose treating in detail. I do not suppose I shall state anything but what most gardeners of good experience already know. Mushroom-growing, however, is very much on the increase, and it is for the many persons who do not know how to grow Mushrooms that the following directions are given.

In order to be better understood, we will suppose that Mushrooms are required for table the whole year round, when it will be proper to commence in the month of August, at the time that out-door cultivation ceases. My plan is to first give the Mushroom house a thorough cleansing by clearing out all rubbish, washing the woodwork, and whitewashing the walls, by searching every hole or crevice for woodlice, crickets, and other enemies to the Mushroom, and by fumigating with tobacco and two or three times with sulphur, in order to destroy any winged insect that is likely to prove destructive. While this is being done, collect all the fresh horse-droppings that are to be had from the stables until enough are procured for the size of the bed. Place them in an open shed or under some protection from wet, which should not in any case be allowed to reach them, turn the manure frequently, and mix it well. When the strongest heat has abated I add a third of leaves partly decayed, and after mixing these well with the dung I consider it is ready to form into a bed. If the bed is to be formed on the ground floor I first lay just enough rough material to keep the manure clear of the cold earth, then put on a layer 6 inches thick over the bed, and either beat it well with a mallet, or even tread it if the manure will allow of it. Afterwards I add another layer or two, and each time repeat the operation of treading or beating down, so as to reduce the bed to a solid mass of the requisite thickness, which with me is generally from 1 foot to 14 inches. After this insert two or three trial sticks into the bed, and examine them frequently.

If all go on well, in five days or a week the bed will be fermenting mildly and regularly. When the proper heat has been secured uniformly over the bed, which can be very nearly ascertained by the trial sticks or else by a thermometer, which should indicate 80° F. or even 85° Fah., the bed may be prepared for spawning. First harden the surface by gently beating with the spade, and then make holes with a large wooden dibble about 3 inches square with a small but short point. These should be about 2 inches deep, 3 inches in diameter, and about 8 inches apart, and at regular intervals all over the bed. Allow the bed to remain in this state about two days, when the inside of the holes will be dry and in a fit state to receive the spawn, which may be put-in in one piece or several. Every hole should be filled with it, and have it well beaten into them afterwards. Cover the bed with a thin layer of the short dung, and make it firm and level. In about ten days or a fortnight examine the holes, and if the spawn has spread well into the material of the bed it may be earthed-over and finished-off.

I think it will be well to say a few words on earthing the beds, because on this their success or failure greatly depends. In the first place, the earth used should be a rich, moderately retentive maiden loam. If this be too light it will not remain firm on the bed, the Mushrooms will therefore be weak and of inferior quality, and the bed will cease bearing much earlier; but if the soil be heavy it can be made solid on the

bed, and the Mushrooms will be thicker in texture, finer, and the bed will produce a good crop and keep in bearing a long time. Again, the earth should neither be too dry nor too wet, but in such a state of moisture as to present a smooth surface when beaten down, and should be put on the bed about 2 inches thick.

I may mention that it is necessary to be very particular in the selection and working-up the materials for the growth of Mushrooms. It is one of the most curious and delicate operations in gardening, for if the bed becomes too hot after spawning, or if the materials are worked-up in too wet a state, the chances are that the spawn will be much injured if not entirely destroyed by these two extremes. If destroyed by heat, fresh spawn must be inserted when the material has declined to the proper temperature; but when too wet the bed must be worked up again, and fresh dry material added.

The after-treatment of the beds depends in a great measure upon the sort of house they are placed in. If there are hot-water pipes, the heating of which should be properly under control, it will not be always necessary to use a covering of hay or straw, which generally serves as a breeding place for woodlice and other pests. If used at all it need only be very thinly scattered over the bed, the principal object being to keep the surface of the bed in a uniform state of temperature and moisture. In a house of fair dimensions containing four or more beds at work very little heating by the hot-water pipes will be necessary, unless the weather is severe or the crop is required to be pushed forward. I prefer to grow my Mushrooms without fire heat, as they are then more fleshy, the bed lasts longer in bearing, and very little if any watering is required. This latter process should not be done without good judgment, as it is easy to overwater a bed and kill the spawn, or cool it so much that the bed will not recover its original temperature. Water should be applied in a warm state, and put on the bed by sprinklings with a fine syringe or a fine-rosed water-pot, with the greatest caution, or the little Mushrooms just peeping through will be injured so much as to turn brown and die away. The temperature of the house should be kept very regular, and not above 55° nor below 50°.

To keep up a proper succession of Mushrooms much must of course depend upon the demand, but as a rule it will be sufficient to spawn a new bed every month, as the beds will not all work alike. Some produce in five weeks, while another will be seven or even eight weeks before doing so; but as a good bed generally keeps in bearing a long time no blank will occur from such irregularity, unless the demand should be excessive at one particular time.

I think I have now given the principal details of the culture of Mushrooms in a regular Mushroom house, which is the best place to grow them in through the autumn and winter months. I have not, however, spoken of ventilation, the means of applying which are not always provided for. In a Mushroom house a little air at times is necessary, and if given with caution it will prove an additional help to regulate the temperature of the house. There should also be the means provided for excluding the light, as it appears more natural for Mushrooms to grow in the dark, though I am not sure that it is so. They have, however, a much better appearance, and some assert that they are better flavoured. A Mushroom house is one of the least expensive structures to have about a garden both in the working and construction; but there are, nevertheless, very many large gardens where Mushrooms are grown without one, though it is hardly fair to expect a gardener to keep up a supply without such a convenience. In this case the spawn is imperfectly worked; the beds, too, even if made up in proper succession, will often come into bearing all at one time, and frequently not at all.

I have intended the above remarks only to apply to the culture of Mushrooms through the autumn, winter, and spring months, the time when there is generally the greatest demand for them. For summer cultivation a Mushroom house is not so much needed, and I believe many gardeners, myself among the number, do not use it at that time, but grow their crops out of doors with little protection beyond a covering of rough littery straw or bracken to shelter the bed from excessively heavy rains, and to keep the temperature regular. The beds are made up in various forms, suited to the spot selected for them, but the ridge-shape is that usually employed, and from such beds Mushrooms are produced in great quantities.

There are very many ways of growing Mushrooms. My first attempt was by forming a bed in a small stokehole over the boiler with spawn of my own making. I have also grown them in large pots plunged in a bed of leaves in a forcing vinery. Some grow them in boxes, tubs, or even old hampers, and place them in a Peach house at work, or any other convenient place where artificial heat can be given them. Others make-up beds in cellars, which prove to be very good places generally, because of the ease with which an even temperature can be maintained. Others, again, who can spare a frame, insert spawn in a well-spent Melon or Cucumber bed with not very unsatisfactory results. Still, as I have before hinted, such modes are only chance methods of keeping up a supply, though they answer excellently where an unlimited and regular supply is not the main object, and to those who have no Mushroom house, or even the convenience of getting materials for good beds, such a system is to be recommended. It should be remembered, however, that in whatever way they are grown, the same care in selecting and working-up the materials, and also in the making-up and regulating the temperature of the beds, must be very strictly attended to, in which case success is pretty sure to follow.—Thomas Record.

VINE DISEASE AND VINE STOCKS.

(*Concluded from page* 142.)

Several years since I became convinced that the great cause of the decline of the Grape Vine in the United States, was referable to a large extent to some disease affecting the roots. I examined the roots of a number of varieties, and found that those varieties possessing thick succulent roots were the most unhealthy. Among those examined I found that the Concord had the finest and most wiry roots; and without recognising the disease, I resolved to use the Concord as a stock for both native and foreign varieties, and I think that in the autumn of 1868 I directed the attention of your readers to the advantages that would probably result from the use of the Concord as a stock for varieties of Vitis vinifera. Since the publication of the valuable articles on the Grape louse, I am more than ever convinced of the importance of working the more valuable varieties upon the Concord. If this pest has obtained a foothold in England, I fear its ravages will become general; for during one of its stages of existence, that of the Grape-leaf gall, it may be easily disseminated on the growing plants, and at certain periods when it possesses wings it may be wafted by the wind from place to place. Again, when the Vine is dormant the pest has its home on the roots, and it may be widely dispersed by the distribution of Vines from an infected nursery.

Observation having taught me that the want of success in Vine culture in this country was the sequence of some disease of the roots of the Vine, during the summer of 1868 I inarched a number of foreign varieties on Concord stocks growing in pots. In the spring of 1869 I planted a lean-to house 120 feet long with Vines upon their own roots, and with others inarched on Concord stocks. The first year (1869) they made a satisfactory growth; the second season (1870) all promised well until about the beginning of July, when I found that those on their own roots did not grow so rapidly as the worked Vines. My curiosity being excited I examined the roots of the Vines, and found those of the unworked varieties presented evident traces of disease, whilst those of the Concord stocks were perfectly healthy. Being familiar with the work of Mr. Thomson, I naturally referred the diseased condition to fungoid growths. But the conditions then found I can now refer to the actual cause—the Grape louse. The worked and unworked varieties were growing side by side. In the latter part of October a living fibre could not be found on a foreign Vine within 2 feet of the collar; and to test the condition of the larger roots I pulled up two of the Vines, and to my surprise found the large roots dead. A careful examination of the roots of the Concord stocks revealed the fact, that even the smallest fibres were healthy. From my vinery I proceeded to my garden, and examined the roots of Concord, Ives' Seedling, and Christine, all native, and supposed healthy and vigorous varieties. The roots of the first I found healthy, and those of the latter much diseased. I was anxious to find a reason, and recollected that the preceding spring I had manured my garden with manure containing a small quantity of sawdust, and jumped at the conclusion that the sawdust had produced fungoid disease.

Upon carefully examining the Vines in the vinery I found that the varieties that had suffered to the greatest extent were Hamburghs, Black Alicante, Royal Ascot, Golden Hamburgh, and Mrs. Pince's Muscat. During the summer of 1870, as I expected to change my place of residence, I propagated a number of foreign varieties by cuttings, and grew them in large

pots in the affected house, training the young Vines between the branches of those growing in the border. I likewise inarched a number of the diseased Vines on Concord stocks grown in 8-inch pots for that purpose. About the 1st of November the Vines on their own roots, as well as those on the Concord stocks, were placed on the floor of the vinery, and covered with a sufficient thickness of straw to effectually exclude the frost; the result was—I protected the Vine louse, and enabled the pest to prey upon my Vine roots during the winter. I disposed of my residence, and in March made preparations to pack up my valuable collection of pot-grown Vines and transport them to my new home. To my surprise and disgust, I found the roots of my Vines dead to the collar in almost every case where they were unworked. The worked Vines, on the contrary, were found to be healthy. Again fungoid disease came to my assistance, although the Vines had been grown in a compost consisting of decayed sods and half-inch bones.

On the 10th of last May I finished a span-roofed vinery 55 feet long, and planted it with the inarched Vines raised in 1870, and with a few Vines upon their own roots. The border was made of green turf cut 3 inches thick, to which were added half a ton of crushed bones and 200 lbs. of superphosphate of lime. Although the border was made of fresh sods, and the Vines were planted on the 10th of May, they made a satisfactory growth. The Vines on their own roots, except Golden Champion, made a growth of 13 to 20 feet; but most of the worked Vines crossed to the opposite side of the house, making a growth of 28 feet, the canes being large, firm, close-jointed, and ripened to the tip. When the canes reached the opposite side of the house they were stopped, or else I might have recorded the production of longer canes. Among some of the varieties making the strongest and longest growth on the Concord I may mention Golden Champion, Black Monukka, White Frontignan, Black Muscat of Alexandria, Gros Colman, Black Hamburgh, and Bowood Muscat.

Having noticed in the Journal that the Golden Champion failed in some places to make a satisfactory growth, I resolved upon trying an experiment with this variety. I planted a strong Vine of this variety upon its own roots, and two on Concord stocks grown in 8-inch pots. The Vine on its own roots made a growth of 5 feet, wood spongy and imperfectly ripened. One Vine on Concord produced a stout cane 25 feet long, close-jointed, solid, and ripened to the tip. The other Vine made two canes, one 23 feet long, and the other 28 feet long; the latter 3¼ inches in circumference, firm, close-jointed, and perfectly ripened to the last joint.

I may again direct the attention of your readers to the advantages of using a few of the American Grapes as stocks. They will grow luxuriantly in a soil where the European varieties would languish and die. They are almost exempt from the ravages of the Vine louse, and if attacked seem to sustain but little if any injury. They are injured to the same extent as foreign varieties by defective drainage. To insure a vigorous growth a limited extent of border will supply their wants. In this country the Concord is known as "the Grape for the Million," and it can be found growing with the utmost vigour in almost every portion of the United States, in all kinds of soil, and in every situation—in fact, it flourishes and annually produces large crops of fruit where other varieties would languish and die.

After having inarched a large number of varieties upon the Concord I have found but three varieties that seem to dislike the connection—the Wantage, Syrian, and Nice. As it is more than probable that you will be troubled with the Grape louse in England, I sincerely hope that some of your leading Grape-growers will test the value of the Concord as a stock. If disposed to experiment with it, I would only be too happy to forward cuttings of the Concord to any of your leading Grape-growers; and as you have my name and address, you are at liberty to communicate the same to those desirous of experimenting.

The researches of Mr. Riley during the summer of 1871 in France with regard to the introduction of the plant louse, render it almost conclusive that its introduction was the result of importing American Vines into France. Hence, I would advise your Grape-growers to be careful, and if they require Vines from the United States to be satisfied to receive cuttings, and allow rooted Vines to remain on this side of the Atlantic.

Having discovered my enemy, I shall make him a study, and at some future time I may have something more to say about the Vine louse, and my hobby the Concord Grape as a stock.—Al Fresco, *New Jersey, U.S.*

CHEMISTRY OF MANURE.

Though agreeing with "J. S. K." in the main, yet I cannot accept all the dicta of agricultural chemists as to manures. I know many of your readers will think I have a maggot in my brain on this subject, and I am only now in a measure repeating what I have already said. There is a degree of simplicity in valuing manures altogether by the nitrogen they contain, that seems to recommend itself on this score. Plants cannot absorb nitrogen from the air—plants require nitrogen for their growth—ammonia contains nitrogen—therefore nitrogenous manures are valuable in proportion to the ammonia or nitrogen they contain. There is something delightfully simple and easy in this mode of argument; but I must say, the more I see, the more I hear, and the more I read on the subject, the less convinced I am it is true. Granted (which is not yet proved, and difficult to prove), that plants cannot assimilate nitrogen from the air—but still granted, for the sake of argument, that they cannot—is it to be supposed that when growing plants on an average contain only about 2 per cent. of nitrogen and 50 per cent. of carbon, farmyard manure, for instance, is to be valued merely for the nitrogen when it is rich in carbon in a form easily assimilated, and rich, too, in all the mineral ingredients in a soluble, or rather in a minutely subdivided form, as they have already been absorbed and assimilated by other plants?

Is it not true, also, that all nitrogenous manures are easily decomposed? and may we not argue that just as food which is most easily digested forms the most useful and necessary food for man, so those manures which are most easily decomposed form the most necessary food for plants? Ammonia is an alkali, a powerful solvent for all forms of carbon. Carbon, we are told, can be taken in by the leaves; but leaves give off carbonic acid as well as absorb it, and it is very questionable whether they do not give off quite as much as they assimilate for the plant; and it is more than probable that the greatest bulk of carbon—more than half the weight on an average of all growing crops—is taken in through their roots. Hydrogen, too, is found in growing plants in a greater proportion than nitrogen, not merely as H O—that is, in combination with oxygen as water, but in addition. Persons are apt to say this hydrogen is easily obtained from water by decomposition; but is water easily decomposed? By no means. It is this valuable property of water which makes it so useful as a solvent, that nearly all chemical salts, spirits, sugars, &c., are soluble in water without abstracting either the oxygen or hydrogen in it. Potassium and sodium are nearly the only known substances which have so great an affinity for oxygen as to decompose water, which they do by liberating hydrogen. We can also decompose water by means of powerful galvanic batteries; but as a general rule, it may be said that when once hydrogen and oxygen have entered into combination to form water there is no more stable element. I cannot see, then, that the hydrogen which exists in plants in combination with other chemical constituents besides water, can be easily obtained by the decomposition of water; and I believe that one of the important properties of ammonia, which is readily decomposed, is to give a plant hydrogen as well as nitrogen.

Again, if we make nitrogen the basis on which to reckon the value of manure, what becomes of carbonate of lime, superphosphates, common salt (chloride of sodium), potash, a most powerful manure, and other chemical manures which contain no nitrogen at all? I cannot agree, then, with "J. S. K." that "soot, malt sweepings, nitrate of soda, sulphate of ammonia, guano, all simply depend, or nearly so, on some form of nitrogen for their efficacy. For instance, soot contains carbon in a highly divided, highly soluble form, besides other important salts. Malt sweepings contain no great amount of nitrogen but a great amount of easily decomposed carbon. I need not, however, dwell upon this.

Iron is certainly an important ingredient in the colouring matter of plants, and, though it is very difficult to prove, I cannot help believing that there are certain substances which are taken up by the plants in their sap which may be valuable in helping the plants to assimilate other food, just as many medicines are found to be useful in the human system which are not assimilated into the system, or, at all events, are not necessary to the human system. We know that plants can take soluble substances not necessary to their existence into

their tissues through the sap, as experiments to that effect have been tried with colouring matter; but I do not think our chemical experiments with respect to the physiology of plants are sufficiently advanced to say whether certain substances may not act at times as stimulants to growth as well as being built up as food; and I am strongly convinced that ammonia itself acts as a stimulant, and helps in that way to induce growth, just as much as heat and moisture do.

I will not add more on this head as it is only speculative, but let me repeat one argument with respect to nitrogen that I have already used in your columns, and that is, that as nitrogen is the most inert (inactive, that is to say) chemical agent, as its tendency when in combination is always to set itself free again, when it constitutes four-fifths of the air we breathe, and is only of use as a diluent to mix, as it were, with the oxygen to prevent the oxygen being too powerful—just as we mix water with brandy to make it less injurious—it is contrary to the whole course of nature to put plants and animals in the midst of this superabundance of nitrogen, to find only a small proportion of it in their systems, and yet to argue that the value of manures and foods depends on this nitrogen. Is it not much more likely that it is only relatively of value, because all substances which contain it are easily decomposed? —C. P. Peach.

Peristrophe salicifolia aureo-variegata.—This has been flowering freely in the stove here all winter. I had a few small plants last autumn which were placed in the stove to get up a stock of it by spring for trial in bedding-out, when, to my surprise, it commenced flowering. The flowers are of a bright rose colour, but rather insignificant, yet looking extremely pretty mixed with more gaudy flowers in winter. It is worthy of a place among choice plants owing to its lovely foliage; the leaves are deep green with a golden band in the centre. The plants here are growing in peat and sand. It is a Javanese plant.—James Smith, *Exton Park, Rutland.*

KEEPING GRAPES IN BOTTLES OF WATER.

We have received from Mr. Neshit, gardener to Sir T. Whichcote, Bart., Aswarby Hall, Lincolnshire, specimens of Lady Downe's and Muscat of Alexandria Grapes, the former of which has been cut and kept in water for sixteen weeks, and the latter eighteen weeks. Both were as plump and firm as if they had been recently cut from the Vine, and were equally succulent; but there was an evident loss of flavour. The perfume had quite or all but left the Muscat of Alexandria, which, so far as flavour went, might have been White Tokay; and Lady Downe's were sweet without bouquet. Notwithstanding these evident deficiencies both sorts were in the most perfect state of preservation, and served as a sufficient proof that the method of keeping Grapes in water-bottles during winter, though at the expense of flavour in the fruit, affords the advantage of enabling the fruit to be gathered and stored early, while it is preserved in a condition to be served at table as fresh in appearance as when taken from the Vine.

We shall be very glad to receive any information on this subject from those who have practised this plan. A week or two ago we gave a description of the arrangements for this purpose in the gardens of Earl Brownlow, at Belton, where the quantity of water taken up by the Grapes was so great as to burst the berries.—Eds.

I have kept Grapes, Lady Downe's principally, with the ends of the bunches inserted in bottles of water, for four seasons, and they have kept as well as when left on the Vine. The room in which they are is dark, very little ventilated, and warmed by one of Joyce's patent stoves, in which specially prepared charcoal is burned to keep the frost out, though in severe weather the thermometer has sometimes registered 30° Fahr., or 2° of frost. I cut the Grapes between Christmas and New Year's-day, and this year I took six very large bunches of Gros Guillaume, about thirty of Lady Downe's, and twelve of Mrs. Pince. Clear glass bottles are the best to use, as those made of opaque glass cannot be refilled without spilling the water. Mr. Moore says, "Many gardeners of standing doubt the possibility of Grapes taking up water." There is no doubt that they do take up water, as the bottles in which the stalks of Lady Downe's and Mrs. Pince were inserted required refilling twice a-week, but as soon as a bunch was cut the waste of water in seven days was scarcely perceptible. As bearing somewhat on Mr. Ferme's statement, the waste of water from the bottles in which were the Gros Guillaume was very little in proportion to that from the bottles in which were Mrs. Pince and Lady Downe's. The reason of this was soon apparent, as the footstalks began to shrivel, and every one of the bunches soon had the appearance of shanking.

The berries are still plump, but, as may be expected, no water is now taken up. The stalks of the other two sorts still remain fresh, and the berries still continue to absorb the same quantity of water. I have never weighed any bunches myself before hanging them up, but it would be interesting to do so, then weigh the water they absorb, and afterwards weigh the bunches. I always use rain water with a few lumps of charcoal in the bottle, and have never found the berries crack. I think the system a good one, a great boon to gardeners, and a great saving of fuel to employers. I hope others of our readers will give their experience.—J. Douglas.

BOX-EDGING AND THE TREE BOX.

Amongst the many excellent maxims and the sound practical advice which the worthy writer of "Doings of the Last Week" from time to time places before us, there is one to which I am strongly disposed to make an exception, and that is the trimming of Box-edgings. "R. F." recommends this to be done in the spring, which is, no doubt, the time most suited to the welfare of the plant, but certainly not the best for cutting in order to secure a neat edging during the greatest number of months in the year. I make this statement on the assumption that the Box is only cut once a-year, which, with the slow-growing variety generally used for edgings, is in most cases sufficient. If the cutting is done at the end of March or in April, the Box will begin to grow again soon afterwards, and by July will have attained nearly its full growth, in which condition it must remain till the following March or April. Now although I by no means approve of close-shaven Box-edgings but rather of those which have been trimmed by means of a kind of knife-pruning, still this last mode can only be adopted where the quantity is limited or labour easily obtainable. Assuming, therefore, that the shears have to be used (and I have even known the scythe), the time and mode of doing it, so as to insure the shortest possible period of unsightliness, appears to deserve attention.

In my practice the best results have been from the cuttings done in the middle of summer rather than from those made in the spring. At the end of June or thereabouts, when the growth of the season is about half made, the Box should be cut in dull weather, by which means the browning of the newly-exposed leaves by the sun is avoided. When after-growth sets in it gives to the edging the appearance of having grown the required height and width, instead of having been trimmed to it. It quickly attains this condition if the weather be at all favourable, and from the month of August till the following May remains in a great measure stationary.

This practice has its drawbacks, for, as showery weather does not always happen when wanted, I have often had to wait till late in July, and on one or two occasions later than that. I always try to have it done in time to allow of a little after-growth, as it is more pleasant to look upon this than for a long time on a saw-cut edge. The cutting of it in moist weather can usually be effected by a little management, and the result will be satisfactory, as it is surprising how quickly the Box recovers its proper hue again compared with what it does in dry weather.

It is much to be wondered at, that of the many plants added to our various lists of the useful and ornamental classes there has not been one to compete with the dwarf Box as an edging of a durable kind; but there are more varieties of Box than one, and now and then an inferior kind gets mixed with the other. In this case the dwarfest variety does not require much clipping for some two or three years after being planted; whereas a stronger grower rushes up several inches high at once. The tree Box proper is also a shrub deserving of cultivation, as it excels in hardiness that of most others. Unfortunately it is of slow growth, and is, therefore, less planted than it ought to be; but there are places for which it is especially fitted, particularly where rabbits abound; and although I have seen Berberis Aquifolium and the common Yew destroyed, and the Rhododendron much injured by these vermin, it is rarely indeed that they attack the common tree Box.

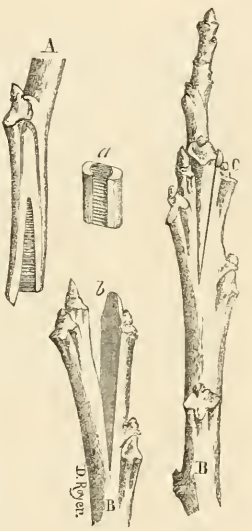
It has often been a mystery to me from whence the Box-

wood is obtained for the many purposes it is said to be applied to. Toys, mathematical instruments, blocks for engraving, and a multitude of other articles are made of this choice wood. I believe in years gone by Turkey, Asia Minor, and adjacent countries furnished supplies, and perhaps may do so yet.—J. Ronson.

GRAFTING THE WALNUT.

As the Walnut will not admit of being grafted after every ordinary method, we have tried several others, and have succeeded in effecting what the Society of Agriculture wished, by means of the same treatment as that to which the Oak and the Vine show themselves amenable—a graft in the cleft of a fork.

It should be done in the spring, just as the sap is beginning to flow, and the buds to swell. The grafts are branches of the previous year kept alive in a dark place among gravelly sand, which does not become so dry as common earth. The union of two kinds whose course of growth is unequal should be avoided, the graft being, in every case, of a kind coeval or less advanced in its nature than the stock. It should be from 3 to 6 inches in length, and cut at the end into a triangular shape—as in the case of a common graft, and placed in a cleft made by splitting up the stock as far as the centre of the knot formed at the forking of two branches. These branches should be shortened to about 10 inches, and the shoots which arise from them pinched as the buds of the graft progress, taking care that the earlier leaves are left to draw up the sap, which they do without starving the graft. In the following August the snags of the stock may be lopped off close to the graft, when the scars will heal before the fall of the leaves.



If the graft be too pithy the cut should be made diagonally, so as to resemble the mouthpiece of a flute, and the bark of the projecting side trimmed off as far as the sapwood. In this case the stock should be cut obliquely, and not vertically. A graft of two-years-old wood at the base will do very well for making the cut upon; but if it be of wood only a year old, care should be taken that it have a terminal bud. The fork in the stock can always easily be obtained by pruning or pinching the leader at the height intended for grafting.—Charles Baltet (in *Bulletin du Cercle Horticole*).

THE ROYAL HORTICULTURAL SOCIETY AT BIRMINGHAM.

Messrs. J. C. Wheeler & Son, Seed-growers, of Gloucester and London, have placed at the disposal of the Local Committee for the Birmingham Show of the Royal Horticultural Society, the sum of ten guineas, to be offered for the best collection of plants in pots, in bloom, bearing sweet-scented flowers, such as Roses, Lilies, Honeysuckles, Stocks, Jasmines, Mignonette, Violets, Carnations, Pinks, &c., ornamentally grouped.

It will have been noticed that a resolution was passed at the public meeting, requesting the Local Committee to give their attention in a special manner to the exhibition of horticultural implements, buildings, &c. If the Special Prize Committee should have ample funds at their disposal, would it not be advisable to open a few classes in which prizes should be offered for manufacturers only, of some of the leading articles? for example, lawn mowers, garden rollers, garden engines, garden seats, vases for different purposes, flower pots ornamental and otherwise, collections of spades, forks, hoes, &c. In addition to these prizes the Judges might visit the stands of all other exhibitors and distribute prizes to articles of merit not included in these classes.—H.

AMONG THE CONIFERS.—No. 3.

Near large towns where the air is tainted with smoke Conifers will not thrive. Exist they certainly will, but their begrimed attenuated appearance is not such as to add to the beauty of the spot on which they are planted. To be called handsome a Conifer should be clothed at the base with a mass of thick foliage, and should rise upwards, tapering gracefully, and being perfectly wanting in heaviness or formality.

When walking lately through a nursery near London, I noticed that whilst the Conifers were in poor condition some large breadths of hybrid and Ponticum Rhododendrons and green Holly were in excellent health. It is worthy of note that two such valuable shrubs thrive so well under conditions trying to the health of most hardy plants.

The various shades of the foliage deserve more attention than has hitherto been given them, as by judicious care in arranging them most charming combinations may be wrought out. Light and shade may here have full play, the sombre hue of Taxus baccata, the common English Yew, finding ample relief from the glaucous foliage of Picea nobilis, or losing all its heaviness when contrasted with the bright-toned Chinese Juniper—one of the hardiest and most beautiful evergreens in cultivation. Such Pinuses as muricata and insignis with their pleasing green, the Heath-like Retinospora ericoides, the variegated Biota orientalis elegantissima, and Chamæcyparis sphæroidea variegata play an important part here. Flowering shrubs should also be introduced, and the best for this purpose are such trees as Acer rubrum, Acer Negundo variegatum, the snowy Mespilus (Amelanchier Botryapium) (valuable both for its flowers and the beauty of its foliage in autumn), the purple, weeping, and Fern-leaved Beeches, the scarlet and purple Oaks, coccinea and nigra, and the variegated Elm (Ulmus microphylla variegata), a beautiful, but too-little-known tree, of which there are some fine specimens at The Mote, the seat of the Earl of Romney, near Maidstone. Then there are the Weeping Birch, the Fern-leaved Walnut, Liquidamber, and some of the deciduous Magnolias. With such materials beautiful groups might be formed.

This is an interesting work which requires more than a mere superficial acquaintance of the plants on the part of the planter, whose aim should be so to arrange them that they shall not only produce a pleasing effect in the first instance, but also annually increase in beauty, individually and collectively. To obtain such a desirable result there must be no crowding. Close attention also should also be given to the habits of growth, so that they may be graduated from the tallest kinds down to the front ranks, where even the dwarf Savins, tamariscifolia and prostrata, find a place as an appropriate edging. Here come some of the other dwarf-growing kinds, such as Abies pumila, pygmæa, and elegans, the dense clanbrasiliana, the pretty Thuja ericoides and many of the Junipers, which form an interesting fringe to the taller and more graceful kinds. In addition to these the following afford a rich variety in form, colour, and height:—Abies orientalis, the bright-coloured Thuja (Biota) elegantissima, Chamæcyparis sphæroidea glauca, Cupressus Lawsoniana erecta viridis, so fine in form and bright in colour, Cupressus Lawsoniana gracilis, Juniperus thurifera, Thujopsis dolabrata, and Abies Albertiana, which with its pendulous branches rivals that of canadensis. Then there is the Weeping Spruce (Abies excelsa inverta), the Swiss Stone Pine (Pinus Cembra), a distinct kind, of a close rigid aspect, but with its branches so disposed as to form a handsome pyramid. It is one of those kinds that acquire beauty with age. Cedrus atlantica, and Salisburia adiantifolia also deserve a place. Like the Deodar, Cedrus atlantica varies very much in the colour of its foliage, being in some instances of a dull green, and in others of a bright silvery hue. There are others not so symmetrical in form, but having beautiful foliage. The most remarkable of these are Pinus Benthamiana with deep green foliage nearly a foot in length, and Pinus macrocarpa, a valuable and distinct variety, having long dense foliage of a greyish

blue tint. These two kinds are distinct, and of such lofty growth as to be equally valuable for their timber as they are for decorative purposes.

Besides being used for the purposes already noticed, many Conifers may be introduced with good effect into large rockeries. All the prostrate dwarf kinds, as the common Savin, the dwarf Juniper (Juniperus nana), and the somewhat higher but equally spreading Juniperus squamata, appear to a great advantage spreading over and among the rocks. Then, too, the pretty dwarf Juniperus hybernica compressa, Thuja ericoides, and other species of a similar compact dwarf habit of growth, blend well either with Ferns or Alpine plants among the nooks and corners of the rocks, while kinds of loftier growth and more graceful habit form a useful shelter. Whenever trees or shrubs are planted for effect, shelter, or the production of timber, there some of this useful genus should find a place. Many of them possess valuable economic properties, but it is improbable that all these kinds will ever attain so full a development in the climate of this country as to render the culture of them desirable when contemplated from such a point of view. It is, however, I think, a subject of sufficient interest to merit a separate paper.—Edward Luckhurst.

ASTROCARYUM MEXICANUM.

The genus Astrocaryum belongs to the Cocoeæ section of the order Palmaceæ (although I am not aware that they are of any value in an economic point of view). It is composed of a few handsome species, and amongst them A. mexicanum, a representation of which we reproduce from M. Alphand's work, is by no means the least elegant.

The species are all more or less armed with long, sharp, and formidable black spines. The genus is distinguished by its unisexual flowers, which, however, are not produced on separate plants, but really upon the same spike. The spikes are simply branched, and the female flowers are confined to the lower portion, and the males to the upper, which would appear to be a wise arrangement of Nature to insure the fertilisation of the flowers, for were their positions reversed impregnation would be extremely problematical. The fruits are oval and single-seeded. In their natural habitats the plants affect the banks of streams and large rivers, and I believe they are seldom found at any great distance from water, which is the general rule with Palms armed with spines. Astrocaryums are slender-stemmed plants, carrying extremely handsome heads of broadly pinnate leaves, which, in A. mexicanum, are dark green on the upper side, and pure white beneath. This species is extremely ornamental in a collection of tropical plants, and is also one of the best for exhibition, either in a collection of Palms or mixed stove and greenhouse plants; but it will never become a small amateur's plant, or a plant for the decoration of apartments, for the simple reason that it will not long retain its beauty out of the temperature of the stove.

Astrocaryum mexicanum.

The soil best adapted for Astrocaryums is a mixture of loam and vegetable mould in the proportion of two parts of the former to one of the latter, adding sufficient sharp river sand to make the whole feel gritty in the hand. The young plants should be potted firmly; and taking into consideration the spiny character of the plant, it must be liberally supplied with water both winter and summer; indeed, in summer it will be highly beneficial to place the pot or tub in a large pan of water.—Experto Crede.

DIELYTRA SPECTABILIS CULTURE.

The opening Fruit and Floral Meetings of this year at South Kensington are already distinguished by their great excellence. Not only are the classes in which prizes are offered well filled, but the large and choice collections of Orchids and other plants add very materially to the interest and success of the meetings. There is one notable feature to which I wish to allude at this time, and that is the choice and interesting collections of hardy herbaceous plants. Since the bedding-out mania set in, these exquisite gems of the vegetable kingdom have to a very large extent been ignored. There are now, however, very evident signs of returning popularity, and no doubt ere long nearly every garden will have in some quiet nook its border of choice herbaceous plants. Many of them, though hardy, are amongst the most useful of our decorative plants in-doors, and, with a little forcing, the season of flowering is much prolonged. What would our greenhouses and conserva-

tories be early in spring without a few plants of the Hoteia japonica, with its graceful snow-white inflorescence, or without that exquisite little gem the Lily of the Valley?

Another very useful subject, and a queen amongst herbaceous plants, is the Dielytra spectabilis. A class was specially provided for this flower at the February meeting of the Royal Horticultural Society, and well deserving it is of a class all to itself, for when well grown there are few more beautiful objects than this; several collections were staged at the meeting, but all of them were far behind what the plant is capable of being grown to. I well remember the fine plants of it which used to be exhibited at a small provincial exhibition in Scotland some fifteen or twenty years ago, each plant being furnished with several dozens of gracefully-drooping racemes of its pendant bright rose-coloured flowers. Perhaps Mr. Wemyss, of the gardens, Springwood Park, Kelso, could tell us how they were grown. Each of his plants was a good load for a couple of men.

The Dielytra is, properly speaking, a hardy herbaceous plant, and to grow it successfully it should be treated as such. About the first week in February is a good time to propagate stock. The method of procedure is this:—Lift an old plant from the open border; it may have a score of crowns, more or less. By this time they will have pushed 2 or 3 inches; they should be carefully divided with a sharp knife, a small portion of roots being attached to each. The small plants may be treated in two ways: they may either be planted out at once in the open ground, or each crown may be potted separately in a small pot, and placed in a cold frame, or they will root and grow more freely if placed on a slight hotbed. After the plants are well established and duly hardened-off, they should be planted-out in the open ground. Previous to doing this, the ground should be well trenched and enriched with a liberal application of manure, as the Dielytra is a gross feeder, and its fleshy roots penetrate deeply into the ground. These plants will be useful for flowering the following season in small pots.

If the plants are required to attain a large size they should remain undisturbed in the same position for three or four years. They will flower beautifully in the open ground every season in May or June. Being a native of Siberia, the Dielytra is quite hardy, and requires no protection whatever in winter. I have seen it succeed equally well in light and heavy soils. The best potting material is a compost of four parts turfy loam, one of leaf mould, one of rotted manure, with a small proportion of silver or river sand if the loam is heavy. In forcing, the temperature should not be high until the plants are fairly started into growth, and they should be set close to the glass; if otherwise placed they are apt to become drawn. —J. Douglas.

LATE GRAPES.

Mr. Donaldson's experience with Mrs. Pince, and Mr. Freeman's with Madresfield Court Grapes, have much interested me, and no doubt all your gardening readers as well. The difference of opinion which exists with respect to the keeping qualities of these and other late Grapes has struck me as remarkable. In some places the varieties named are highly prized for their free setting, or freedom from small berries, and sound late keeping, whilst in others small berries or unsymmetrical bunches predominate, and the berries shrivel if left on the Vines beyond the commencement of the new year. What is the cause or causes of such a difference in the result, experience alone can tell us, and I am therefore glad of the observations of Mr. Douglas, Mr. Record, and of "W. D. C." (page 59). It is very desirable that those having to supply Grapes of last year's growth after January 1st should state the varieties they employ and their opinion of their keeping.

My experience is not great, but I will state it. I have a late vinery planted as follows from east to west—1, Muscat of Alexandria; 2, Black Hamburgh; 3, Muscat of Alexandria; 4, Mrs. Pince; 5 and 6, Gros Guillaume; 7, Bowood Muscat; 9 and 9, Lady Downe's; 10, Black Muscat of Alexandria (Muscat Hamburgh); 11 and 12, Black Hamburgh. The varieties are not as contemplated; what I wished for were—1, Muscat of Alexandria; 2, Madresfield Court; 3, Trebbiano; 4, Mrs. Pince; 5 and 6, Gros Guillaume; 7, Bowood Muscat, or Muscat Escholata; 8 and 9, Lady Downe's; 10, White Lady Downe's; 11, Black Muscat of Alexandria; and 12, Alicante. I found the Vines incorrectly labelled, and as they had evidently been planted as ticketed, the Trebbiano, &c., were in an early house. The latter, though ripened in July, is yet firm and crackling.

We did not commence cutting until the middle of December last, and all were plump and sound then, without so much as a damped or shrivelled berry. I do not consider, until we have passed November, or until the leaves fall, that fire heat affects the keeping of Grapes. The first Grapes to show symptoms of shrivelling were Muscat of Alexandria and then Mrs. Pince, neither being presentable after Christmas-day. Bowood Muscat could barely pass muster on New Year's-day; Black Hamburgh, also Black Muscat of Alexandria, keep sound until the close of January, the latter kind being the better of the two. I am here referring to their previous behaviour. Judging from my Vine of Mrs. Pince, the variety is not to be compared with Black Hamburgh for keeping, nor is it nearly so profitable, for it always has a majority of small berries. It is, however, a fine-flavoured Grape. Lady Downe's keeps sound and plump past March, and Gros Guillaume is then by far its superior as regards flavour and juiciness, being with me the finest late Grape.

For a supply of Grapes from the end of September to the New Year no variety surpasses Black Hamburgh, with Muscat of Alexandria as a white Grape: but they should be grown in separate structures, for the Hamburgh requires less heat than the Muscat. The Hamburghs should be thoroughly ripe by the middle of September, and the Muscats of a deep yellow colour. It is well known that unless Grapes are well ripened they will not hang for any length of time in a sound condition. It is questionable if there are any two Grapes equal to these, taking into consideration certainty of crop and quality of produce. If a black Grape with a Muscat flavour be wanted, Mrs. Pince is a finer-looking one in bunch, size of berry, and colour than Black Muscat of Alexandria, and will suit those who like firm flesh. It also retains its flavour longer. Black Muscat of Alexandria, however, is a valuable Grape, and will pass the New Year in a sound state better with me than Mrs. Pince, which I find is the worst-setting of any; yet I have seen Mrs. Pince very fine, and our Vine being young another season may entirely upset prior conclusions. Madresfield Court I have seen very fine late in autumn, but I have no experience of it.

Though agreeing to some extent with "W. D. C." that the keeping quality of Grapes is not dependant on the amount of saccharine matter which they contain, it is certain that the development of the saccharine matter is dependant on the ripening, and if this is not complete the prospect of the Grapes' late-hanging is small. The saccharine matter is greatest in the kinds that shrivel the soonest—namely, the Muscats, and unless it is well developed they will not keep, but will soon damp. When the ripening of such kinds as Lady Downe's is not very complete from want of sun in the autumn, or when it is not finished till late, the thick skin of the berries is not proof against shrivelling at the points of the berries, the part near the footstalk remaining plump and sound.

"W. D. C." considers "the latest section must be filled up with Lady Downe's without any other black Grape." It is undoubtedly the latest-hanging of all, yet I see in Gros Guillaume merits which Lady Downe's does not possess—namely, very much larger bunches and berries, considerably more juice, not nearly so thick a skin, and flesh (as Mr. Rivers would say of the Pear) more melting; Lady Downe's being so firm as to be little better than indiarubber.

I consider we have five Grapes that will hang quite long enough. Those are black Lady Downe's, Alicante, Gros Guillaume, White Lady Downe's, and Trebbiano, which is a good match for Gros Guillaume, as Lady Downe's is for its white namesake. In a house for furnishing Grapes from December to May I should plant these five varieties to the exclusion of all others. I have seen the original Lady Downe's with fine clusters of plump berries at the end of April.—G. Abbey.

THE MANURES FOR CARROTS.

By Cuthbert W. Johnson, F.R.S.

The amount of Carrots grown in our island is hardly so considerable as the value of the root for feeding purposes would lead us to expect. In the year 1870 there were in all England only 13,832 acres grown, in Wales 351, and in Scotland only 1076 acres. For this very limited growth there are, probably, one or two reasons. 1, Carrots are supposed only to succeed on certain deep sandy loams; and 2, It has been doubted whether we well understand the best kind of manure for their growth. Some late researches on this very considerable question are, therefore, well worthy of the reader's careful study. From the general results obtained from these most

valuable inquiries, it would seem that those fertilisers in which ammonia is copiously present produce the best crops of Carrots. Let us remember what has been done in this inquiry in Scotland. It is not very long since that the Highland Society awarded their gold medal to Mr. J. Stevenson, of Cumnock, for his experiments on this root (*Trans. High. Soc.*, vol. 1864, p. 149). He found that the best soil for the Carrot is a sandy loam, either naturally deep or made so. The farm manure for it—thirty to forty loads per acre—should be ploughed-in during the early winter; that of the horse is very excellent for this root. Mr. Stevenson adds 4 cwt. of guano, and 6 cwt. of salt; at Cumnock the Altrincham Carrot seed (8 to 10 lbs. per acre) is not sown till after the middle of April. The Long Red Altrincham, when a large crop, produces from 15 to 20, the common Red Altrincham from 11 to 14 tons per acre. From the result of his trials, Mr. Stevenson concludes that 35 tons of horse dung a year old, five hundred gallons of tank urine, 4 cwt. of guano, and 6 cwt. of salt per acre is the best dressing, and that fresh-made farmyard dung, or cow dung, or ashes, are not so suitable for Carrots. Soot is an excellent manure for Carrots (soot contains a considerable amount of ammonia). The farmer will find, in using soot, that its effect on light soils is materially increased by adding to it from eight to ten bushels of salt per acre.

Then we have the report (*Mark Lane Express*) of the trials of Mr. C. D. Hunter, in the season of 1871, upon Mr. W. Lawson's, Blennerhasset Farm. The results of his trials are given in the subjoined table :—

Manures per acre.	Cost of Manure.	Weight of crop per acre.	Value of crop, less cost of manures.
	£ s. d.	Tons. cwt. lbs	£ s. d.
1. No manure	—	10 16 48	14 1 3
2. Superphosphate 6 cwt., muriate of potash 2 cwt., and sulphate of ammonia 3 cwt.	5 18 0	17 18 14	22 15 0
3. Same as No. 2, but only 2 cwt. of sulphate of ammonia	4 18 0	18 5 70	26 8 7
4. Superphosphate 6 cwt., and sulphate of ammonia 3 cwt.	3 16 0	10 4 42	12 0 9
5. Superphosphate 6 cwt., and muriate of potash 2 cwt.	2 18 0	15 15 0	22 6 0
6. Superphosphate 6 cwt., salt 2 cwt., sulphate of ammonia 2 cwt.	3 17 0	10 6 28	13 3 4
7. Superphosphate 6 cwt., sulphate of magnesia 2 cwt., and sulphate of ammonia 2 cwt.	4 10 0	10 17 56	13 8 10

Upon these results Mr. Hunter remarks that "The value of potash for Carrots upon this soil is well shown by comparing Nos. 2, 3, and 5 against Nos. 4, 6, 7, the three potash plots giving nearly 7 tons per acre more weight. In plot 2 the extra cwt. of sulphate of ammonia does not seem to have been of use, but the reverse; and No. 5, which got more, and was on inferior land, comes so well up to Nos. 2 and 3 that probably 1 cwt. of sulphate of ammonia per acre would have been sufficient. The salt and sulphate of magnesia in Nos. 6 and 7 show a little better than No. 4, but not sufficient to warrant their use. From former experiments I would conclude that Carrots require less ammonia than Potatoes, and would suggest as a suitable dressing per acre for Carrots, 6 cwts. superphosphate, 1½ cwt. muriate of potash (or 3 cwts. of potash salts), and 1 cwt. of sulphate of ammonia." Then, again, the application of the dung of the pigeon has been found a very beneficial application to Carrots. Now this manure contains a very considerable amount of ammonia. When analysed by Professor Anderson (*Trans. High. Soc.*, vol. 1864, p. 170), he found in one hundred parts of the dung of the—

	Pigeon.	Hen.	Duck.	Goose.
Water	58.32	60.88	46.65	77.08
Organic mat. and ammo. salts	28.25	19.22	36.12	13.44
Phosphates	2.69	4.47	3.15	0.89
Carbonate of lime	—	7.65	3.01	—
Sulphate of lime	1.75	—	—	—
Alkaline salts	1.99	1.09	0.32	2.94
Sand	7.00	6.69	10.75	5.65
	100.00	100.00	100.00	100.00
Ammonia	1.75	0.74	0.85	0.67

These valuable examinations, we must remember, were made of the dung of birds living chiefly on vegetable matters. What would be the result upon the composition of their dung by feeding them upon a considerable proportion of animal food we can only judge from analogy. Thus, if we examine the excreta of those birds which feed chiefly on fish, we find that it abounds with uric acid and ammonia. From these analysations we learn why the Peruvian farmers so much prefer the recent guano evacuated by the sea birds to that of the older more decomposed deposits. Dr. Wollaston found that the recently-voided excreta of the gannet, when dry, contained hardly anything but uric acid; and Coindet found in one hundred parts of the solid excrement of the sea eagle—

Ammonia	9.22
Uric Acid	84.65
Phosphate of lime	6.13
	100.00

Several comparative experiments, made some time since by Mr. A. J. Main, of Whitehill, in East Lothian, are in accordance with the examinations of the chemist. He employed both pigeon's and hen's dung, in conjunction with farmyard manure, as a dressing for Carrots, with a result per acre of which the following is a tabular statement :—

Manure employed.	Carrots produced. Tons.	Cwt.
Home-made manure, 24 tons	12	13¾
Home manure 16 tons, pigeon's dung 4 cwt.	14	5¾
Home manure 16 tons, hen dung 4 cwt.	11	12¾
Home manure 16 tons, Peruvian guano 4 cwt.	13	16¾

Another inquiry suggests itself—viz., Whether the growth of the Carrot might not be promoted by being mixed with other plants? I learn from a Scotch clergyman, that in his garden in Stirlingshire he can only grow Carrots successfully mixed with Onions.

WINDOW GARDENING.

The very ring of the name of window gardening is pleasant, and suggests hosts of beautiful parlour gardens, with the Ivy twining around the edges of the window sash; or on a stand in front of the pane is a pot of Geraniums, and over all hangs a basket filled with drooping plants. We are glad to see a growth of taste for plants; a genuine love for flowers promotes the love of home.

Much that is essential to success in the in-door culture of plants must be learned from experience. One great mistake is in a wrong choice of the soil; many often suppose that any soil will do: hence, especially in cities and villages, they are often apt to choose soil from the back yard, unfit for plants' needs, being either too dry, devoid of fertilising material, or already exhausted by continual drafts from the numerous roots of the plants around. The best, and in fact only soil, should be a compost of loam, one part; sand, one part; leaf mould, one part; and well-decayed cow manure, a fourth part. The use of the sand is to assist drainage; the proportions of the manure may be varied according to the needs of the plant. Ivies, for instance, need a rich soil, but bulbs generally need little or none, pure sand being much the best for the last, which should never come in contact with manure. The sand should be well mixed with the compost. In the bottom of every vessel, box, or basket, there should be laid a few bits of broken crockery for the more perfect flow and drainage of surplus water. Most vessels have holes in the bottom also, but in hanging baskets this cannot be expected, so the crockery must take its place.

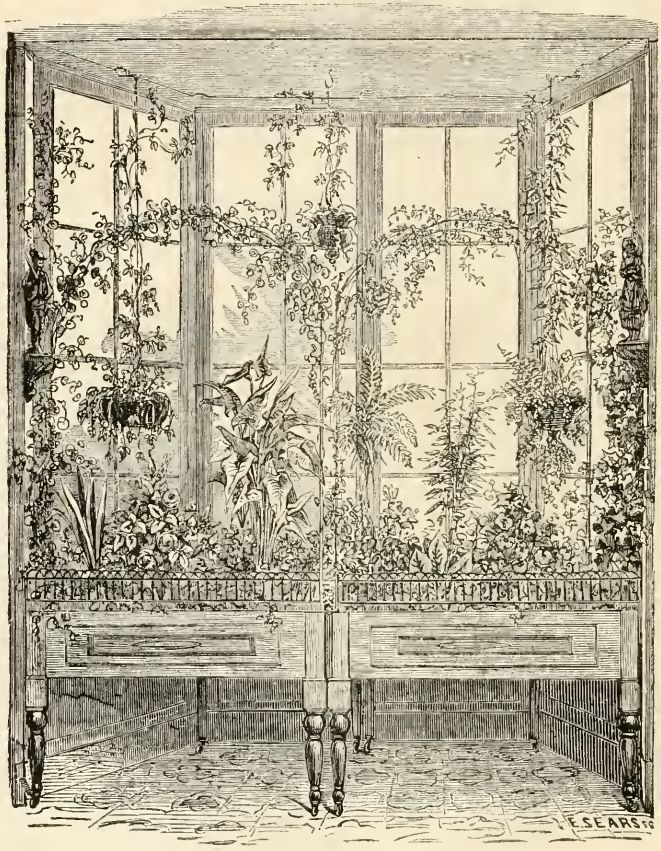
Select plants of good short-jointed stocky habits with leaves of healthy look; large specimens are not desirable. It is better to get those plants which are well started, and are growing finely, and then let them develope gradually. When you have obtained your new plants, be careful of too sudden a change from the old quarters to the new. This hasty transition is very trying to plants. The hot dry air of the living-room is a severe test upon any plant brought from the cool outer air, or the moist atmosphere of the florist's greenhouse. It would be best that this change should be gradual. Just bring them in-doors, and place them in a room without a fire for a short time. If you have a light dry cellar, this will be a good place, if not liable to frost. Here they need only moderate watering. After a short time they can be transferred to the window; here they must enjoy plenty of light. In mild weather, pull down the upper window and ventilate the air; keep their foliage free from dust and insects; wash them with a sponge, and syringe the plants with a good supply of water once a-day. If the water soaks away in the soil rapidly, then it is in good condition. Never water when the soil is already full of moisture; never water at mid-day, or when the sun is shining.

Avoid very high temperatures, and also guard against low ones; a temperature of 60° to 70° in the day, equable and uni-

form, is a good medium, but at night it should range from 40° to 50°. Beware of the danger of frost. Many housekeepers, in letting their fires go out at night, often forget their plants, and in the morning awake to find a sudden change of weather, frost on the window pane, and their plants tipped also. It is a safe plan to throw newspapers over the plants between them and the window.

All plants suitable for greenhouses needing much heat, should be avoided for ordinary parlour culture; only the more simple plants that can be easily managed should be used, but Geraniums, Azaleas, Daphne, Yellow Jasmine, Oxalis, Fuchsias, are always desirable and easily managed.

The design of a window garden of which we give a drawing, is one actually in use. The bow window is about 6 feet wide and 3 feet deep. A double stand has been made to fill it up, and the boxes inside are lined with zinc, filled with compost, and covered with moss. A wire framework is placed in front for ornament, and from the centre and sides rises an archway of wire whereon are growing some climbing Vines. The plants placed in these boxes are Madeira Vine, Manrandyas, Mexican



WINDOW GARDEN DESIGN

Cobæa, Calla, Roses, Carnations, Fuchsias, Amaranths, Coleus, and Begonias.

The hanging vase over the centre arch contains a plant of the Coliseum Ivy. On a bracket just at the edge of the window sashes is a dish of Ferns. At the left hand is a hanging basket filled with Moss, and plants of the Oxalis and Tradescantia; another basket at the right contains the Ice Plant, as well as the Tradescantia.—(*The Horticulturist.*)

POTATOES AND TOBACCO.

These plants are much closer allied and associated in many ways than the unsciencèd reader may suspect. The botanist places them in the same natural order—Solanaceæ. The chemist shows that they each contain an alkali, poisonous to some animals—solanine in the Potato, and nicotine in the Tobacco. They were brought into use almost simultaneously, and by the same man. Their use was at first opposed and neglected, and now their consumption is among the largest of all vegetable products. The duty paid last year on Tobacco was £6,613,668, and although more than one and a half million of acres are annually occupied by crops of Potatoes, yet there are also imported annually about one million and a half cwts. of this

tuber. Tobacco has become the greatest leaf-luxury of life, and the Potato "the bread-root" of the British Isles. The man who introduced their use into our native islands was Sir Walter Raleigh; I spell his name as he spelt it himself. To detail the events of his biography would not be suitable to your columns, but I must note a few relative facts and traditions. When at Bieton last year I looked down from the Tower in the lower plantation upon Hayes Barton and its surroundings —a combination of one of the most beautiful seacoast and land views in South Devon. Hayes, in 1552, was the birthplace of Sir Walter Raleigh. It is near to a large wood of that name, which adjoins the village of Yettington, and is about half a mile from the western entrance to the Bieton demesne. The house is now occupied by one of the tenantry on the Rolle estate, and is distant somewhere about one mile from Budleigh Salterton, in a south-westerly direction. There are several antique chairs in the Swiss cottage in Bieton arboretum, which are said formed part of the property of Sir Walter, and they as well as a bust of Sir Walter, are placed in a niche of the temple.

It is disputed whether Sir Walter introduced the Tobacco plant into England, but Stowe says that he first made known the smoking of "the weed." James I., "when all men wondered what it meant," detested frantically "the precious stink," as he calls it in his "Counterblast to Tobacco," and so inveterately pursued measures to prevent its use, that the tradition is that Sir Walter, who was a smoker, was obliged to row to a rock in the river Dart to use his pipe, and the place is still known as "Sir Walter Ralegh's Rock." He was a snuff-taker also, and the box from which he took a pinch when about to kneel down before the headsman was disposed of for £6 at the sale of the late Duke of Sussex's personal property. Sir Walter's having introduced Tobacco would not aid those who endeavoured to move the king to save him from execution. So offensive was it to that most selfish and weakest of monarchs, and so general had the use of "the weed" become, that the Cambridge University authorities warned scholars in 1614-15 not to go into a "Tobacco shop," nor "to take Tobacco in St. Marie's Church, or in Trinity Colledge Hall," during the king's visit. One of Sir Walter's residences near London was the house now known as the Pied Bull Inn, at Islington. There is an engraving of this house in the sixty-first volume of the "Gentleman's Magazine," and then, 1791, in one of the rooms a coat of arms had upon it a Tobacco plant between two sea horses. I now pass to the association of Sir Walter with the Potato, and relative to this I have nothing to add to the following notes published by me some years since.

Sir Walter Ralegh's Birthplace.

The positive testimony of Gerard proves that the Potato was forwarded to him from Virginia; and how they reached that province of North America will be made to appear probable by the suggestions of Humboldt. Gerard, we may conclude, received the tubers from some of the settlers in Virginia, who emigrated thither about twelve years previously, in 1584, under a patent granted by Queen Elizabeth to Sir Walter Ralegh. And thus much is certain, that, in 1693, Sir Robert Southwell, President of the Royal Society, communicated to that learned body the fact that his grandfather first cultivated the Potato in Ireland, and that he obtained it from Ralegh. Tradition states, further, that Sir Walter himself also had the root planted on his estate near Youghall, in the South of Ireland; and that he gave them to his gardener as a desirable fruit from America. When the berries were ripe in September, the gardener brought them to his master, with the inquiry of disappointment, "Sir, are these the fine American fruit?" Sir Walter, either really or pretendingly ignorant of the Potato's habit, desired them to be dug up as weeds, and thrown away; but in doing this the tubers were revealed, and found to be the available produce.

Humboldt rationally concludes that the Virginian colonists obtained the Potato from the Spanish settlements, for it is quite clear that it is not a native of Virginia nor even of intervening Mexico, and that it was cultivated in Spain and Italy before it was made known in England from Virginia.

Although the Potato was known to English botanists in 1596, yet horticulture was too ignorantly practised in this country to permit its rapid introduction among our cultivated crops. In 1619 they were here a desired yet expensive luxury; for in that year of James I.'s reign, a small dish of them provided for his queen's table cost 1s. per lb., when money was at least twice as valuable as it is now.

Potato cultivation spread rapidly in Ireland; and it became established, it is said, in Lancashire, and that portion of our northern coast still celebrated for its culture, owing to some being on board a vessel wrecked upon its shore. Yet the value of the root was not generally known at a still later period, for in a time of scarcity—namely, in the March of 1663, it required to be recommended as a crop of national importance in a letter addressed to the Royal Society. The writer of this letter was Mr. Buckland, a Somersetshire gentleman; and the recommendation was referred for consideration to a committee by the Society. The report of that committee was favourable, and the Society not only urged its cultivation to landed proprietors, but requested Mr. Evelyn to enforce the Society's opinion in his "Sylva," then publishing under its auspices, although it was no favourite with him; for in 1664, in his "Kalendarium Hortense," he says, "Plant Potatoes in February in your worst ground." Before the "Sylva" appeared — namely, in 1664, was published a pamphlet, the first devoted to the subject of cultivating the Potato, and bearing this prolix title—"England's happiness increased, or a sure and easy remedy against all succeeding dear years, by a plantation of the roots called Potatoes, whereof (with the addition of Wheat flour) excellent, good, and wholesome bread may be made, every year, eight or nine months together, for half the charges as formerly. Also, by the planting of these roots, ten thousand men in England and Wales, who know not how to live or what to do to get a maintenance for their families, may, of one acre of ground, make £30 per annum. Invented and published, for the good of the poorer sorts, by John Forster, Gent., of Harslop, in Buckinghamshire."

Notwithstanding the widely-disseminated opinions of the Royal Society, and these published appeals to the public, the introduction of the Potato as an object of cultivation was extremely slow.

Worlidge, in 1687, although he remarked that the Potato was then common in some parts of the continent, merely suggests that they may be useful for swine or other cattle.

Houghton, writing in 1699, says they were then very common in Lancashire, being introduced from Ireland, and that they began to spread over England. The roots were boiled or roasted, and eaten with butter and sugar!—(*Collections*, ii., 468.)

Sharrock, Ray, Lisle, Bradley, Mortimer, &c., writing at the close of the seventeenth, and early in the eighteenth century, make most slighting mention of the Potato; and even Miller, in the quarto edition of his dictionary, published as late as 1771, only mentions the same two varieties, the red and the white-tubered, which had been noticed by writers a century his predecessors.

Salmon, who wrote in 1711, speaks of the Virginian, and the English, or Irish Potato, as distinct kinds, though his description shows their identity—the only difference being, that the colour of the skin of the tubers of the first was dirty white, and

of the second red. "They are only nursed-up in gardens in England and Ireland, where they flourish and come to perfection, prodigiously increasing to a vast plenty. The roots are boiled, baked, or roasted."—(*Salmon's Herbal*, 905.)

London and Wise, in the seventh edition of their "Compleat Gardener," published in 1719, do not even mention the Potato (but it must be remembered that this is only an abridged translation of M. Quintinye's work, published some years previously). However, even as late as about 1770, the Potato was not known generally in our south-western counties. Mr. Knight, then President of the Horticultural Society, writing in 1831, when he was seventy-two years of age, says—

"I can just recollect the time when the Potato was unknown to the peasantry of Herefordshire, whose gardens were then almost exclusively occupied by different varieties of the Cabbage. Their food, at that period, chiefly consisted of bread and cheese, with the produce of their garden, and tea was unknown to them. About sixty years ago, before the Potato was introduced into their gardens, agues had been so extremely prevalent, that the periods in which they, or their families, had been afflicted with that disorder were the eras to which I usually heard them refer in speaking of past events; and I recollect being cautioned by them frequently not to stand exposed to the sun in May, lest I should get an ague.

"The Potato was then cultivated in small quantities in the gardens of gentlemen; but it was not thought to afford wholesome nutriment, and was supposed by many to possess deleterious qualities.

"The prejudices of all parties, however, disappeared so rapidly, that within ten years the Potato had almost wholly driven the Cabbage from the garden of the cottagers."—(*Knight's Papers*, 319).—G.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Loosen the surface of the soil amongst all growing crops, to admit the air and otherwise sweeten it. It is a very good plan in planting-out subjects that are at all tender at an uncertain season, to throw up the ground in good strong ridges running east and west, planting on the south side of the ridge. The plants are thus sheltered from the north winds, and fully exposed to the sun. Prepare stations for *Cauliflowers* and *Lettuces* that have been wintered under glass, selecting a sheltered deep rich piece of ground. *Basil* and *Marjoram* may now be sown in pans in a hothouse. Ground should be prepared for *Carrots*, *Parsnips*, and *Onions*. Trench and otherwise prepare ground for plantations of *Rhubarb* and *Sea-kale*. Plant the principal crop of Ashleaf or other early *Potatoes*. Make fresh plantations of Sorrel, of which the large French Sorrel is much the best.

FRUIT GARDEN.

Should the weather continue mild the wall trees will require nailing and pruning. Where canvas cannot be obtained, fir boughs or wooden copings should be employed to ward off the effects of frosts, which an early spring renders both probable and dangerous. Clear away dead leaves from Strawberry plants, and remove superfluous runners from the Alpine Strawberry. All should not be removed, as the runners generally bear better than the old seedling plants. Gooseberries, Currants, Filberts, and all standard fruit trees ought to be kept clear in the centre, so as to have a full surface exposed to light inside as well as outside.

FLOWER GARDEN.

Proceed with Rose-pruning, many sorts of which the late mild weather has already advanced; an exception, however, may be made of Roses recently moved. Plant and lay Rhododendrons. Trained Magnolias should be secured to the wall, and Pomegranates and tender shrubs uncovered. Conifers may be planted-out or removed. Edgings required for flower-beds (such as Box, Thrift, Daisies), should at once be planted, and Box edgings cut. Plant Pinks, Pansies, and Carnations. The laying of turf should be gone on with, and all planting and pruning completed for the present. The Dahlias are now in full course of propagation with the large growers for sale. The amateur may strike the young shoots in a common hot-bed, which, if properly managed, is easily accomplished. The first thick shoots do not emit roots so well as those which are more slender; but, generally speaking, for small establishments it is the best plan to start the roots in heat, and then divide them, each division having a shoot attached to it. We are glad to find that the merits of fancy Dahlias are now more appreciated. Most certainly they have improved much in form, and what we now want is a dwarf race not exceeding 2 feet in height, for, as they now grow, their large size and coarse growth necessarily exclude them from small gardens. Mild showers occasionally would be of service to Auriculas, and when grown in wooden frames, a brick placed under each corner whilst the weather is open would contribute to their health and well-doing. Some people top-dress their plants with rich and stimulating soil at this period, but we do not admire the system of adding anything stronger than thoroughly-decomposed cowdung mixed with an equal bulk of decayed leaves. This will grow them well without any risk of poisoning the plants. Ranunculuses may now be planted whenever the soil is sufficiently dry. Place them in rows about 6 inches apart, 4 inches from root to root, and cover them with 3 inches of soil. The seed should be sown in thoroughly-drained pans or boxes, filled with fine sandy soil and leaf mould. Water this well the night previous to sowing, scatter the seed on the surface thickly, and cover very thinly; then dip a brush in water and sprinkle the soil, so that no seeds are uncovered, and then place them in a cold frame from which frost is carefully excluded.

GREENHOUSE AND CONSERVATORY.

No time should be lost in cleaning and pruning the plants occupying the beds in the conservatory, if the season of flowering is to be retarded; but pruning may be performed later. Orange trees, Lemons, Citrons, Limes, and Shaddocks should be cleaned and top-dressed. Fuchsias should be allowed to grow, and cuttings obtained as soon as the shoots are sufficiently forward. Pot Pelargoniums, Cinerarias, and Calceolarias, and keep them close for a day or two after the operation. Green fly must be repressed by fumigation. Pot Verbenas to supply cuttings. Heliotropes may also be placed in heat for the same purpose. Cut those Heaths that have finished flowering, and clear away all dead flowers. Give air freely both night and day, but do not allow a sudden cold easterly wind to sear and scorch up the plants. The many beautiful New Holland plants may be expected in full flower at this time. Be very careful for a short time in the application of water to plants that have about finished flowering. The mode of airing as directed for Heaths cut back, such as Epacris and Pimeleas that are going out of flower, holds good.

STOVE.

Prepare a dung pit or frame for the growth of young stock of stove plants, and when the heat is sweet and wholesome place 2 or 3 inches of cinder ashes over the bed, and as soon as these are warmed the place will be ready for the reception of the plants. In places where the more modern method of growing plants over tank heat is pursued, it will be well to secure the assistance of a little well-fermented dung to plunge the pots in. I find dung heat will recover plants which, under any other treatment, would inevitably perish. Some good stocky plants of Clerodendrons and Ixoras should be potted and placed in a hotbed of dung. The former delight in a free open soil, consisting of loam, peat, and leaf mould, with a little rotten cow dung, and some charcoal and silver sand, whilst the Ixoras flourish in pure turfy peat with charcoal and gritty sand. If the plants are well rooted give a liberal shift, but do not overdo it. In addition to these plants may be named Dipladenia splendens, Cyrtoceras reflexum, Allamanda cathartica and A. grandiflora, Lucnlia gratissima and L. Pinceana, Gardenias, Schubertia graveolens, Stephanotis, &c. The showy Impatiens Jerdoniæ should also be encouraged by every possible means to make wood, and should be propagated as quickly and freely as possible, for it is just the plant that is wanted for autumn decoration, as are such softwooded plants as Gesneras, Achimenes, &c. In the management of the pit or house keep a fine growing heat of from 60° to 70°; shut it up early in the afternoon, but open the sashes a little before leaving it for the night.

PITS AND FRAMES.

Attend carefully to the stock of bedding plants, and get rooted cuttings potted-off as soon as they are in a fit state for that purpose, encouraging them with a gentle bottom heat and careful management to make quick growth, for after this season there is no time to be lost with young stock. Tender annuals must now receive attention. Heat is indispensable to the raising of these, though not necessary to flowering them. Begin sowing this month, and continue to the end of April in pans placed close to the glass, in a temperature of from 60° to

65°. Keep the soil moist, and shade from bright sunshine. Great care must be exercised to prevent the plants from damping-off or getting "drawn" from want of air. As soon as they can be handled prick-off singly into small pots, or place them round the edge of a 4-inch pot, plunging them in a gentle heat till they can be safely trusted in the open borders. They may also be pricked-out in rows in a spent hotbed, shaded carefully, and give plenty of air when the weather will permit of it. It is of the greatest importance to sow early to secure fine plants and a profusion of bloom.—W. Keane.

DOINGS OF THE LAST WEEK.

By placing our earth in narrow stacks and thatching them with turf, we generally obtain it dry and sweet enough for using a year after being so treated. Finely broken charred rubbish, with lime and soot, will be found effectual in keeping away all obnoxious animals from those spots where they are likely to do harm. Stirred the surface soil among vegetables, sowed Beans and Peas, and prepared the ground intended for roots and Onions. Potatoes we shall plant as soon as the soil is more mellow and drier. If the weather continue to be wet sow them in shallow drills, and cover them with such dry sifted material as charred rubbish.

FRUIT GARDEN.

Pruning should be done now, as trees are likely to be weakened if it is put off until late. Wash the earliest Pears and Cherries, by means of an ordinary syringe, with a solution of quicklime to keep the birds away. We are keeping back our orchard-house trees as much as possible, by giving them air both by day, and by night so long as we can do so with safety. Soft soap and quassia water will destroy the Aphis persicæ should it make its appearance. The smoke formed by burning tobacco and bruised laurel leaves together will be found very effective; but there should be but few air-holes for it to escape by, and great care should be taken, by covering with damp moss, that it does not break into a flame, as thence comes the hot smoke that injures the plants. This treatment is generally very successful, as the prussic acid of the laurel and the nicotine of the tobacco, being conveyed into every little nook by means of the smoke, are doubly fatal to the insects. It is better to do it when the buds are just swelling, as the trees will stand it better than when they are in leaf and the young fruit is just set. We prefer several slight smokings to one heavy one, as the latter is likely to do harm. To thoroughly clean an empty house the old lime should be washed off by scrubbing and using boiling water, and new put on so as to fill up all cracks which might serve as harbours for insects or their eggs. We generally mix a little lampblack with the whitewash to lessen its brightness, and thus reduce the reflection of heat from the wall, which is sometimes so powerful as to cause burning. A mixture of softsoap water and sulphur laid along the top part of the back wall will also be found of use for keeping away insects.

We have not tried to obtain fruit from Strawberry plants very early, and have therefore had scarcely a blind plant. No water should be allowed to remain in the saucer before the fruit begins to swell; indeed it would perhaps be better if beginners kept their plants altogether on boards.

ORNAMENTAL DEPARTMENT.

It is better to keep for a year or two young plants which have been just bought, and transplant them to their positions when wanted, instead of doing so directly they arrive. In the description of the manner of fixing trees by means of fir poles (page 155) the word "driven" was incorrectly substituted for the simple one "sunk"—that is, the young Firs are taken up as roughly as they can be brought away, and placed just as they are in holes triangularly around the tree that is to be secured. This does away with all the trouble of "driving them in," and they, as a rule, last much longer than those which are so fixed. Should the ground be soft the base of the supports can be steadied by stones placed on the outside of them, if the smaller ends are joined to stem of the tree. For smaller trees with only one pole the same plan may be persisted in—that is, the solitary support should be placed in a hole 3 or 4 feet from the tree in a contrary direction to the prevailing wind. Even in this case it is more effectual than if it were driven into the ground near the bole of the tree.

Fuchsias.—We repotted and placed in slight bottom heat small plants just breaking. Large ones kept in a dark shed had broken so freely as to require pruning and then repotting in fresh soil. Such plants kept in the dark should be stopped back rather than pruned, if their owners wish to have a good display of flowers with but little trouble.

Scarlet Geraniums.—Put well-top-dressed plants in a little dry heat to obtain flowers for cutting. We have found this tribe invaluable throughout the winter.

Pelargoniums, Florists' and Fancy.—The most forward ones which we want to blow early will not be repotted, but accelerated by means of manure water as soon as the flower-trusses show. The next lot we will repot shortly without stopping them, whilst the next we will stop once more, after which the younger plants will come in.

Kept dividing and repotting Ferns.

Chrysanthemums.—We will take off cuttings of these in a few days, as it is well to get the plants forward for early flowering. Will make preparations for sowing seeds and striking numbers of plants next week. In such dull weather as we have had cuttings are apt to come weak even with air. The chief thing is to get them to root downwards without drawing upwards thin and weak.

Bulbs seem to bloom more easily than usual this season, requiring less heat than ordinary to bring them in early. I find it is best to harden-off Hyacinths as soon as a few flowers are expanded at the base, so that when removed to a room or a house they continue to open, and therefore remain pleasing for a longer time than when taken when in perfection.

Camellias in flower and opening their buds should be assisted with weak manure. There are many opinions as to the best time of potting them. On the whole, we prefer examining them just when they begin to grow a little after they have done flowering.—R. F.

TRADE CATALOGUES RECEIVED.

Harrison & Sons, Leicester.—*Select Seed Catalogue.*

Laird & Sinclair, Dundee.—*Vegetable and Flower Seeds, &c.*

W. S. Boulton & Co., Rose Lane Works, Norwich.—*Descriptive Catalogue of Lawn Mowers, Wire Netting, Implements, &c.*

Alban Goodman, Londonderry.—*Descriptive Catalogue of Vegetable, Flower, and Farm Seeds.—Descriptive Catalogue of Roses, Fruit Trees, Vines, Flowering Shrubs, &c.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*E. M. L.*).—There is no elementary book on gardening with coloured illustrations, nor is such a book needed. Our "Garden Manual" details the cultivation needed. (*R. H. C.*).—We never heard of such a sixpenny book on butterflies. (*W. Weston*).—The "Handbook of British Plants," by Mr. Notcutt, we think will suit you.

Seedling Cineraria (*I. W. D.*).—The colour is very rich, and petals (florets) stout and free from notch, but we can say no more from seeing a single pip.

Sooly Qua Cucumber (*Cumberland*).—It may be cultivated like any other variety. See page 130 of our present volume.

Dissolving Bones (*F. Corbold*).—The meaning of "unleached" is explained in answer to another correspondent. If sulphuric acid is used instead of the alkaline ashes, the best vessel to dissolve the bones in is an old hogshead that is watertight. You will require a weight of sulphuric acid equal to one-half that of the bones. The finer the bones are, the sooner will they dissolve.

Watercresses (*R. H. C.*).—You must use offsets. The mode of culture is described in our No. 474.

Unleached Ashes (*Bung*).—Wood ashes that have not had the alkali washed out of them are intended.

Maiden Peach in a Pot (*A Young Beginner*).—Shorten the side shoots to 9 inches and the leader one-third, and if you pinch the young shoots judiciously this summer you will have fruit next year.

Hardy Conifers (*Subscriber*).—Gordon's "The Pinetum" will suit you.

Plants near Laurel Hedge (*A Constant Subscriber*).—In so narrow a border as 1½ foot we do not think anything will grow, and we should only have a marginal line of Vinca elegantissima, which would contrast well with the green of the Laurel. It is of little use attempting anything in the way of flowers where rabbits are so destructive, but you may have Geraniums in the border in summer. If the border had had an east or west aspect we should have advised Primroses, Oxlips, and Violets, and they would do on the south if they were shaded with grass in summer.

Salt for Asparagus (*R. T. S.*).—We consider two dressings quite sufficient—namely, one about the middle of March, and another the second or third week in May, each at the rate of half a pound per square yard.

Violets for Succession (*Idem*).—We grow the Single Russian, Czar, Double Russian, Reine des Violets, King of Violets, Devoniensis, and Neapolitan. These include early and late kinds.

Cineraria Drooping—Potting Achimenes (*Antony*).—This, no doubt, is due to the dry atmosphere caused by the gas, which is very injurious to plant life. Could you not leave the plants in the window? Plant the Achimenes in a pan well drained, and filled with a compost of two parts fibrous loam, one part leaf soil, half a part of silver sand, and the like quantity of sandy peat, sifting and placing the rough over the drainage, and over it the fine soil to within half an inch of the rim. Then place the roots about 1½ inch apart-

and cover half an inch deep with fine soil. Place them in a hotbed, or house with a temperature of from 60 to 65°, and keep the soil just moist. When flowering they may be placed in a cooler house, and should be returned to the warm house to ripen the growth.

BULBS FROM ITALY (*A. M. F.*).—The corms of Cyclamens, and roots of all plants, are best taken up when the leaves begin to fail or turn yellow. Lift them carefully, removing most of the soil, and packing them in dry moss. They are safe for transit if packed in any dry material, the chaff or husk of hemp, or any kind of seed, being suitable.

CYCLAMEN PERSICUM SEED NOT GERMINATING (*J. C. R.*).—Seed sown a month ago will probably yet germinate, but the temperature is rather low to bring up the seedlings quickly. Place the pans in a hotbed, with an atmospheric temperature of 65 at night, and a bottom heat of 70 to 75°, and we think the seedlings will shortly appear. If you wish them to flower well next winter grow them in a hotbed or Cucumber frame during the summer. Last year we had some sown early in April; the plant did not appear for more than a month. They were grown in frames on dung beds throughout the summer, and now we have them in 6-inch pots, with an abundance of fine foliage and flowers, the former finely marbled, and the latter varied in colour, and some sweetly scented.

FRUIT TREE FOR PLANTING AGAINST SOUTH WALL IN YARD (*Glerum*).—You could not have anything more profitable than an Apricot, and the kind we advise is Hemskerk. You can procure of most nurserymen a standard, giving it plenty of good soil, and leaving the surface clear of stones or gravel for about a yard from the stem. It may be necessary to protect the stem of the tree from cattle.

EPACRISES AFTER FLOWERING (*A Constant Subscriber*).—When the flowering is over, or in April, cut the plants back to within an inch or two of the old wood, and in a fortnight place them in a pit or house with a temperature of from 45° to 50°, giving abundance of air, and watering moderately. To induce free breaking afford a rather moist atmosphere. When they have shoots an inch long repot, if necessary, and shade them for a few days until they are re-established; then give abundance of air, and grow them in a pit or airy house, not far from the glass, throughout the summer. We do not find it necessary to thin the shoots; but to give compactness of growth, from the end of June to the middle of July we stop all the shoots to 6 inches in length, and continue the plants in a cold house throughout the summer, the main point being to have the growth well perfected before autumn. To secure this well-ventilated greenhouse in winter, an l dry, for if close and moist they will the plants require an abundance of air and light, and grow them in a pit or start into growth instead of flowering. We think it is a recommendation that Camellias that the flowers are not all expanded at once. You may bring them on more rapidly by giving them a temperature of from 45° to 50° at night—quite sufficient for Camellias.

SEEDS AND CUTTINGS IN A PACKING-CASE (*W. T.*).—You may raise half-hardy annuals in your packing-case, but instead of filling it half full of stable manure we should fill it to within 9 inches of the top, and tread or ram the manure firmly, taking care that it is of a nature not likely to heat very violently, nor give off rank steam. To prevent its doing so it should be thrown into a heap, watered if dry, and turned over after it has been in the heap a week, and again in three or four days, when it may be placed in the case; 4 inches of soil will be sufficient. You may also use it for cuttings, but for that purpose it would be well to have a division across the case—a thin partition of wood will do. Reserve one division for the cuttings, and the other part for the seeds. The cuttings should be kept close and shaded from sun; but the seeds, as soon as the plants appear, will need air and light: hence the necessity for the partition. Cuttings from the country will answer if put in before their vitality is destroyed by delay.

PLANT FOR NORTH-WEST WALL (*H. T.*).—We fear Clematis Jackmani would not succeed well against a wall with a north-west aspect. You may give it a trial. C. Fortunei does well with us on such an exposure, and for covering a large space C. Vitalba does excellently, also Jasminum nudiflorum and Crataegus microphylla. Marechal Niel Rose would not do. It requires a south or south-west aspect. Ivies are the best covering for such a wall, and we should plant Hedera digitata, H. Helix folbis variegatis, and H. Regneriana, placing the variegated in centre.

OLD RHODODENDRON AND TREE PEONY TRANSPLANTING (*An Old Subscriber*).—You can safely remove these, though forty years old, for both move with good balls, which you should take care to preserve. To make success more certain, cut off any irregularity of growth in both, especially the Peony, and Crataegus microphylla. Marechal Niel Rose would not do. It requires a As soon after this as the ground is in good order, or during March, transplant them—the earlier the better. Water freely after planting to settle the soil about the roots, and mulch with partially-decayed leaves and old cow dung.

PEACH TREES IN POTS CASTING THEIR BUDS (*Constant Reader*).—It arises from the defective formation of the buds, and may be occasioned by the soil being too dry, or by attacks of red spider. The only remedy is giving a good supply of water, and paying due regard to keeping the roots in a healthy state, and the foliage clean by syringing.

DRESSING FOR FRUIT TREES (*A Weekly Subscriber*).—A good dressing for fruit trees, especially Peaches and Nectarines, may be formed of 4 ozs. soft soap, and tobacco juice, as sold by the manufacturer, one gallon, bringing it to the consistency of thin paint with sulphur vivum. For Vines and the stems of fruit trees it may be used as a thick paint. It does not injure the buds, but in applying it with a brush care should be taken not to dislocate them. The falling of the buds in a previous year was no doubt due to the dressing with the compound you name. All dressings should be applied before the buds begin to swell.

POTTING-OFF ROSE CUTTINGS (*Idem*).—Pot them off now singly in small pots, and place them in the mild hotbed, which will facilitate their rooting. When they are well rooted harden them off, and keep them with slight protection until May, when they may be planted. You could leave them where they are until April, and then pot them off, placing them in a cold frame, and hardening them off for planting out in May. You may, instead, leave them until May, and then plant them out finally, only there is a risk of their failing from the loss of roots, which require very careful treatment; therefore we consider it best to have them established in pots before planting out.

TABLES OR STAGES FOR A VINERY (*R. O. G.*).—Much will depend on whether you intend to make the Vines the principal feature, or, as the vinery opens into the dining-room, whether flowering-plants will not be the main object. By giving the Vines little or no forcing, you can have the house tolerably gay all the dull months of the year without injuring the Vines, and then tender annuals would help to keep up a thin display in summer if the Vines were not too close together overhead. Camellias, Epacrises, Cytisus, Scarlet Geraniums, Chinese Primulas, Cyclamens, herbaceous Calceolarias, Cinerarias, &c., would suit such a house well. For the tables lattiecd ironwork of almost any suitable width may be procured. It is, however, so apt to rust that if used we would recommend it to be galvanised as the most economical in the end, though much more expensive at first. We have no great favour for iron as a material on which to set plants, it is so easily heated and so quickly cooled. We would prefer open wood trellisiwork, say the slats from 1 to 1½ inch thick, from 2½ to 3 inches wide, and with from one-half to three-quarters of an inch opening between them. For uestness of the little upright pillars and the cross bearers might be of iron, but we should be quite satisfied if all were wood. We would in the latter case recommend a sill all the length of the table raised one or two bricks deep above the floor, and in that sill mortice and fix the uprights next the path. The cross-pieces would be joined to these, and to the wall on the sides. The front table or wide-sparred shelf should be flat. If you wish to hold as many small plants as possible, then you should have a stage against the back wall, consisting of from three to six shelves. A vast number of small plants may thus be stored in winter. On the other hand, if that back wall were supplied with a trellis of wire is to have the best appearance from the dining-room, we would cover it entirely with Camellias, Oranges, and say one Heliotrope for scent, and if the most were to be made of them, have no stage. Even here a compromise might be made by having a flat trellised table front and back, with a walk between, and a trellised stage 2½ to 3 feet from the floor; then cover the back wall above the table with such plants as the above, or with climbers, and do not use tall plants for the back table. Several houses like yours have had the back wall covered with Camellias planted out, and were gorgeous in winter and spring, and were improved rather than injured by the shade of the Vines, coming naturally without forcing in summer.

FLOWER GARDEN PLANS (*A Young Gardener*).—All the three proposed arrangements are so good that we cannot decide which is the best. We incline, however, to No. 2, and would make no change except substituting Iresine Lindenii for an edging instead of Perilla, as it bears nipping better. We presume your beds are small and will not permit of much edging, otherwise the edging makes a good finish. The centre of your group, six clumps, seems to be filled with yellow-tinted-leaved Geraniums, and the centre, the largest of all, with white variegated-leaved Geraniums, as Bijou. If these six beds cannot well be altered, and we presume you speak of Coleus, then we would fill the centre, 9, with Coleus Verschaffelti, with a band of Bijou Geranium or Centaurea candidissima. Then, were we to go further we would recommend a suppose 5 and 13, and use a bright Scarlet Geranium as Emily Moreland or Vesuvius, or a blue Verbena as Blue Perfection, or both mixed. Then 14 and 2 we would, as proposed, plant with Amy Hogg, and 1 and 17 with Mrs. Pollock, edged and mixed with blue Lobelia, pumila or speciosa. This, with the addition of the Coleus, would blend and balance your Coleus better in our opinion.

COMMON GARDEN LILY NOT FLOWERING (*J. Parker*).—The cause of the plants not flowering is, that they are in a very stiff soil and a cold situation. In a light, rich, sandy soil and open situation, sheltered from cutting winds they generally bloom abundantly. Take up the bulls carefully, remove some of the offsets, and plant them with the ball entire, so that the crown may be at the depth of 3 inches below the surface. If the clumps are very large they may be divided, but this would rather disturb the roots. Rich, well-drained, light soil, with sandy peat and old cow dung, will grow them well. We think they will flower this year.

TOMATO FOR POTS (*M. G.*).—For growing in pots use Orangefield Dwarf. Sow in a hotbed in March, pot off the seedlings singly when large enough to handle, and shift them into larger pots as their roots increase. From 6-inch pots they may be shifted into 9 or 11-inch pots for fruiting, and be placed in the greenhouse in May. For the wall we advise Hepper's Goliath.

SOWING STOCKS (*Idem*).—The best Stocks for sowing in March or the beginning of April are Dwarf German Ten-week, Pyramidal Large-flowering, and Emperor Sow them in well-drained pans filled to the rim with a compost of two parts loam, one part leaf soil, and a free admixture of sharp sand. Place them in a gently heated hotbed, and when the seedlings are up admit air freely and let them near the glass. Water them very carefully, and give plenty of air to prevent damping off. When they show the rough leaves prick them off about three-quarters of an inch apart into a frame over a very slightly heated bed, and give them abundance of air. The Phlox and Dianthus may be treated in the same way, planting them out in May in rich light soil about a foot apart every way.

PLANTS FOR RIBBON BORDER (*Idem*).—In addition to Cerastium, Pyre thrum, and Dell's Beet, you may raise from seed Cineraria maritima, silvery foliage, 1 foot; Oxalis tropæoloides, dark bronze foliage, half a foot; and Perilla nankinensis, bronze-purple foliage, 1½ feet. They should be treated as half-hardy annuals, and planted out at the close of May.

NYMPHÆA ALBA SEED SOWING (*A. A. M.*).—Line the bottom of your fountain with a foot of mud or of strong rich loam, cover this with 18 inches to 2 feet of water, and drop the seeds in at about a foot apart. No covering is necessary for the seed. We should prefer plants to sowing seed, as some time must elapse before the seedlings flower, even should they grow, which is not always to be depended on.

DWARF PEAS (*Ex-Florist*).—For a first crop Maclean's Little Gem, which is only a few days later than the very earliest. It is the best of all the dwarf Peas, and may be sown throughout the season, or from now up to July. Waterloo Dwarf Branching Marrow is an excellent late kind. The Delphiniums may be obtained from the principal florists advertising in our columns.

RED-SKINNED FLOURBALL POTATO (*L. A. N.*).—Our correspondent says it produces very well, but a worse Potato he never tasted; they have not improved with keeping, boil yellow, and instead of a flourball, are something like a ball of soap, and have a very disagreeable taste.

DIGGING BETWEEN RASPBERRY ROWS (*C. S.*).—We have for many years given up the pernicious practice of digging between the rows of Raspberries. Instead of that we give a top-dressing, about 6 inches thick, of rather littery manure in December, and leave it to till it disappears. We consider the whole of the ground between the rows and plants. We pull up the suckers when they are about a foot high, leaving about six or eight of the best to each stool. They bear abundantly, therefore we recommend the practice.

GREENHOUSE PLANTS FOR TABLE DECORATION (*Florist*).—You restrict us to plants that may be grown in a pit during the summer, and a greenhouse during the winter. We would grow Cyclamen persicum varieties largely, and a packet of seed sown now will give rise to what will be fine plants this time next year. Primulas are also fine; Deutzia gracilis and Dielytra spectabilis are good hardy plants that do with slight forcing or a greenhouse; Spiræa japonica, also a hardy plant, with gentle forcing is excellent; Epacrises;

Ericas hyemalis and ciliaris; Epiphyllums on stems about a foot high, and Monochætum ensiferum, are the flowering plants we advise. The only plants we prefer to these are Azaleas, which when neatly trained and not too tall are surpassed by but few flowering plants. Of foliage plants we advise the following, but they must not be large:—Bambusa Fortunei variegata, Chamærops excelsa, Coprosma Baueriana variegata, Corypha australis, Dracæna australis, Eurya latifolia variegata, Isolepis gracilis, Lomatia elegantissima, Sesforthia elegans, Yucca aloifolia variegata, Y. filamentosa and variegata, and Y. quadricolor.

Seeds from Australia (*Nelly*).—Sow all the seeds you have received, and when they come up you can, if you like, retain two of each and dispose of the rest to friends. All will succeed in a greenhouse, and we will give you some information respecting them. 1 and 2, Acacias, are mostly fine yellow-flowered plants. 3, New Zealand Flax (Phormium tenax) is an herbaceous perennial, hardy in some situations, and a fine ornamental greenhouse plant. 4, Lancewood or Grass Tree (Xanthorrhœa hastilis) has a stem like a Palm, with a head formed of long grassy leaves, spreading out and hanging down in elegant curves. 5, Goodia latifolia, greenhouse evergreen shrub, with yellow flowers in early summer. 6, Hakea eucalyptoides, greenhouse evergreen shrub, with white flowers in early summer. 7 We do not know anything of. 8, Callitris, a coniferous tree that may suit as a small plant for a greenhouse. 9 and 10 we are not acquainted with. 11 and 12, Pittosporum undulatum has white and green flowers, sweet-scented; P. nigrescens, brown; both greenhouse evergreen shrubs. 13, Lagenaria is a form of Bottle Gourd that requires to be sown in hotbed and grown on until June, when it may be planted against a fence in a warm situation; it may also be treated like a Vegetable Marrow. 14, Elæocarpus, greenhouse evergreen tree with white flowers. 15, Goni (Adinandra digitata), said in Dr. Hogg's "Vegetable Kingdom" to be the "greatest vegetable wonder of the world." We think, however, the seeds you have under this name are not correct, as it is a native of Senegambia and Guinea. 16, You know, of course, what Clematis is. 17 and 21, We cannot give any account of. 18, Eucalyptus globulus, greenhouse evergreen tree. 19, Hardenbergia, greenhouse evergreen climber with purple flowers. 20, Elæocarpus, evergreen shrubs, requiring a greenhouse. We should sow all in pots well drained, and in a compost of two parts sandy peat, one of light fibrous loam, and a part of sand. Place them in a hotbed of 70° to 75°, keep them just moist, and after the plants show the first pair of rough leaves pot them off singly, but keep them in the hotbed until established; then harden them off, and remove them to the greenhouse.

Woodlice in Sea-kale Pots (*Smash*).—The best remedy for woodlice is to pour boiling water on them where it can be practised, but in your case we should be satisfied with taking off the covers of the pots and dusting with quicklime. We do not know what other means you can adopt without injury to the Sea-kale.

Names of Plants (*H. D. Nash*).—One of the narrower-leaved forms of Eriostemon myoporoides of De Candolle, a well-known greenhouse plant. Native of Australia.

POULTRY, BEE, AND PIGEON CHRONICLE.

TRIMMING BIRDS FOR EXHIBITION.

Men who take third-class tickets yet ride in first-class carriages; men who utter counterfeit coin; men who commit forgery; and men who trim in any way birds they exhibit for prizes, are all felons—their crimes are alike, for they all cunningly and secretly endeavour to benefit themselves by injuring others.

We have spared no one who has been detected in fraudulently trimming his birds, and we have proclaimed the names of the criminals just as we have often hung up thievish magpies to warn their kindred from similar thefts. Yet bird-trimmers, like surviving magpies, are not quite scared from their felonies.

The bird-trimmers, indeed, are rather increasing in number and boldness, so that one of our best authorities has written to us that some stringent measures are needed to protect honest exhibitors. We hold the same opinion, and we recommend all committees to have the following clause inserted in their forms of entry, and beneath which clause each intending exhibitor has to sign his name—

"I hereby agree that if the birds I exhibit are trimmed they shall be forfeited to the Committee, to be sold by them, and the money received for them paid to the funds of the county hospital, or of some other public charity."

POLAND FOWLS.

As a breeder of those beautiful Poland fowls during many years, I cannot refrain from saying a few words in reply to Mr. Boothby's letter. I think it would be much better, if committees of poultry shows cannot afford a separate class for each of the three varieties, to reduce the prizes and entrance fees to enable them to do so. But by all means let us have separate classes, as I think none of the Poland exhibitors wish to see the birds all huddled together in one class, which, besides, would increase the labour of the Judges in making the awards satisfactorily. Like Mr. Boothby, I think that the good, sound, and clear lacing or spangling should not altogether be ignored for the large crest.

With regard to the qualities of the three varieties as egg-producers, I find the White-crested Black the most prolific, and next the Silvers. I should not like to see any of them degenerate at our shows. In my opinion they are the most ornamental fowls that go into a show, and certainly none are more admired by visitors.—J. Dean.

LAST YEAR'S JUDGING—RULES.

Among the regulations of our poultry societies the following was formerly almost invariably inserted:—"Gentlemen of acknowledged ability and judgment will be appointed to award the prizes." It is curious to observe now with what uniformity this rule "has become conspicuous by its absence." The omission of this rule is, I apprehend, one fertile source of the "wide-spread" dissatisfaction alluded to by your correspondent Mr. J. E. Kell. I lately knew an instance of a person sending a really good pen of poultry, in excellent condition, to an exhibition, where they were unnoticed. They had previously been winners in the keenest competition. The owner was dissatisfied, he could attach no blame to the managers, they were protected by their rule, "The decision of the Judge will in all cases be final." The exhibitor must bear the disappointment caused by his indiscretion; he had sent his birds to a show where the prizes had been, awarded shall I say?——no, distributed by a gentleman whose ability and judgment were "unknown to (poultry) fame."

I have for some time past adopted a course, which if generally pursued by exhibitors would, I believe, materially lessen the "wide-spread dissatisfaction." Except under very special circumstances I never enter my poultry for a show where the name of the Judge has not either been announced together with the schedule of prizes, or in an advertisement in the Journal, previous to the day named for receiving the entries. If I entrust valuable poultry to the care of a committee and incur an outlay in entry fees and travelling expenses, I claim as a guarantee of good faith on their part an assurance that the prizes shall be awarded by a competent and able Judge. I have frequently observed that where the name of "our oldest and ablest Judge" has been announced, a large entry and good competition have been the result; on the other hand, when the name of the Judge has been withheld, a species of mistrust has been manifest by a correspondingly meagre entry. I have, I think, showed to demonstration that it is to the mutual interest of both managers and exhibitors that the ablest and most disinterested Judges should be appointed. By the adoption of some such process as I have submitted the "new blood" proposed may exercise a healthy influence on judging, and relieve our most popular Judges in some measure of their onerous duties.

There is yet one stereotyped rule in the list which needs amendment. I have had ocular demonstration of the definition of the words, "None but those actually engaged in the arrangements of the show will be admitted previous to its opening," &c. Presenting myself for admission to an exhibition on one occasion I found I had mistaken the hour; a glass door barred my entry to the room, but did not prevent my observing who were the persons actually engaged in the arrangements. There were the committee and secretaries actively engaged arranging the numbers of the pens, and all honour to them. What a staff of assistants they have! I see several well-known exhibitors, owners who had charge of their specimens, and, "last but not least," the attendants of certain famed poultry-yards. See; one of these latter gentlemen, having carefully ensconsed his favourites in their pen, is "actually engaged." A late consignment of birds remain to be placed in their respective pens. He kindly volunteers his aid. "Be careful of the tail of that Game cock," I could have exclaimed (he was removed from the basket so hastily); but the bustle of those actually engaged and the din of the cocks crowing, &c., would have rendered any advice inaudible. I remain a silent spectator. The time for the arrival of the Judges draws near; the attendant returns to his carefully-attended pen to give the finishing touch; with the daintiest morsels he persuades them to further inflate their well-distended crops (they are of the large variety—a well-filled crop is not without its advantage). A soft clean handkerchief is carefully passed over them, their wings and tails are re-adjusted, and all is ready for the Judges. They are detained a few seconds, two or three baskets have just arrived from a long distance, time enough remains to place them in their pens, and the Judges commence their work. The fine condition of the carefully-attended pen, the contented appearance contributed by a well-filled crop, secure

for them the highest honour. With the limited time at the disposal of the Judges, they are misled by the unfair preference conceded to birds with, perhaps, slipped wings concealed and wry tails during the time they examine them remaining erect; thus they take precedence of the half-famished, late-arrived, but more perfect occupants of the adjoining pen.

To meet this source of complaint a rule ought to be in force compelling all persons, whether owners or attendants, to deliver up their specimens at the doors of the exhibition, and on no pretence ought an exhibitor to be allowed to enter the show before the awards are given.

I endorse every word Mr. Kell uses as to exhibiting against dealers. Only give us an assurance that gentlemen of ability who, like one or two of our oldest Judges, exercise a courteous neutrality to the interest of exhibitors of every grade, and a guarantee that the same measure of advantage will be conceded to all exhibitors alike, and I am sure the result will be that the winning pens will contain the best birds, and that the "wide-spread dissatisfaction" will materially decrease. Unless some such steps be taken to check the system of "touting," which has increased so rapidly of late, many honourable and ardent fanciers will be alienated from the pursuit of a fascinating and pleasant pastime.—Veritas.

NEW BOOK.

The Illustrated Book of Poultry. By L. Wright, *Author of "The Practical Poultry-Keeper," &c. Illustrated with Fifty Coloured Plates of Celebrated Prize Birds of Every Breed, &c.* London: Cassell, Petter, & Galpin.

Most heartily and sincerely do I recommend this work (Part I. of which is now before me) to our poultry-fanciers, breeders, and exhibitors. The size of the number is just that of our Journal—a convenient size; and when the fifty numbers are bound it will form an ornamental as well as suitable book for the drawing-room table. To speak of Mr. Wright's powers as a writer is unnecessary, but he has evidently become even clearer in description than formerly. He begins with a chapter on Houses and Accommodation, giving woodcuts to illustrate his ideas; woodcuts of various yards—the smaller; the larger, as Mr. Tudman's; and the largest, Lady Gwyder's at Stoke Park. Then we have a plan of Mr. Beldon's poultry house, once a factory. All these plans are large in size and well drawn. Chapter II. takes the important subject "The Selection of Stock." This is a thoroughly practical chapter, and deserves being studied by those who are not feather-fanciers or exhibitors, but persons desirous of making an honest penny by poultry; and I venture to think that poultry as a food question will be more and more considered in days when all butcher's meat except pork is at a famine price. Chapter III. speaks of "Feeding and General Treatment of Fowls," in the middle of which the number ends.

And now a special word for the coloured illustrations. They are drawn by Mr. Ludlow, whose spirited and specially life-like and character-giving Pigeon portraits have adorned our pages. I have laid the portraits of the Buff Cochin cock and hen in this No. 1 side by side with every former portrait of the birds published, and it is wonderful how superior they are. Not only the outline is accurate, but the expression of the Cochin face is given with marvellous fidelity. If all the portraits equal these two, fanciers will have accurate models up to which to breed. The type of the work is bold and clear, and the printing goes straight across the page, which is always a gain.

Part I. is to be ready for general distribution with the March magazines. No doubt the work will have a large circulation in both Britain and America. In the latter country poultry is beginning to be specially studied.—Wiltshire Rector.

Poultry and Pigeon Show at Oxford.—It is proposed to hold a Show in Oxford some time in October. It is supported with great zeal by several influential gentlemen. Three cups are already promised. Oxford, from its central situation, and having railway communication with all parts of the country, possesses unusual facilities for fanciers sending their stock. A meeting was held on the 21st, in the Town Hall Buildings, to choose a committee, elect officers, and provide a guarantee fund.

Rabbits at Northampton.—To show we appreciate the energy displayed by the Northampton Committee, I have started a subscription towards an extra cup for Rabbits, to be given as the majority of subscribers think best, and to be competed for by subscribers only, so that, whatever small amount may be given, it will enable them to compete for the cup. Let me at once appeal to all fanciers to help me forward, as the time is getting on. I have, I am happy to say, met with good success, and have the following promises already made:—Mr. J. Boyle, jun., 10*s.*; Mr. A. H. Easten, Hull, 5*s.*; Mr. Charles King, London, 5*s.*; Mr. J. Irving, Blackburn, 5*s.*; the Northampton Committee, 7*s.* 6*d.* All subscriptions to be forwarded to—Mr. J. Boyle, jun., *Blackburn, Lancashire.*

SILVER DRAGOON PIGEONS.

Having been requested by several fanciers to state my opinion on the colour of the bar of a Silver Dragoon, I emphatically state it should be dark brown. In support of this the winning birds at the following Shows were Silvers, and had dark brown bars—namely, Birmingham, Any other colour class, first 1867 and 1868, first and second 1869 and 1870, first 1871 (Silver class); first Manchester 1867, Blue or Silver; first Wolverhampton 1868; first Bristol 1870; second Aberdeen 1870; second and highly commended Southampton 1871; second Portsmouth 1872. At the last five Shows all colours competed together. If this is any precedent to go by, and certainly it must be, then brown, and not black, is the proper colour for the bar of a Silver Dragoon. Surely no one will say that the whole of the gentlemen who have judged these Shows gave prizes to birds that have had wrong-coloured bars?

Further, I have for the last six years confined myself, as regards Dragoons, to breeding Silvers, and my experience is, that to produce a bird with a light body (nearly white) it is next to an impossibility to obtain the black bar. Moreover, the winning birds at such Shows as those I have enumerated, especially when shown by leading men, are often purchased by fanciers as stock birds, and when pairing like to like, or even crossing the Silver and a Blue, their progeny to a certainty have brown bars; and as the Silver is acknowledged as a distinct colour, and at Birmingham has a separate class, I maintain that a Silver should be as distinct, and as far from a Blue as a Yellow is from a White.—H. Allsop, *Birmingham.*

MELROSE POULTRY SHOW.

The sixth annual Show of the Waverley Association was held in the Corn Exchange, Melrose, on the 15th and 16th inst. The Hall is well lighted from the roof and very suitable for the purpose. It was quite full of birds, and although some showed signs of the severe treatment they have had during the season, the quality was, as a rule, very good.

Adult *Dorkings* were at the head of the list, and the first prize was awarded to a fine pair of Dark Greys, which also won the cup, the second prize going to Silvers, which were correct in all points. In the young class the prizes were awarded in the same order, both winning pens standing clear of all the rest. The *Spanish* class was for birds of any age. The first prize went to an excellent pair of chickens, and the second to adult birds; the cockerel in the first-named pen was extremely good. In *Cochins* the cocks were by far the best. The hens did not show so well, but the cup for these and the *Brahmas* was awarded to the first-prize Buffs. Only the winning Brahmas were of high merit. The second-prize cock was too yellow. In *Game* both the winners were Black Reds, the second-prize pair being best in quality, but sadly out of feather in tail. In single Game cocks the first was a Pile cockerel, and the second a Black Red cock; the quality of both was all that could be desired, and the contest for honours keen. The entries of Golden-spangled *Hamburghs* were not numerous, but there were some good birds, notably the first-prize pen; the hen in this pair was of extraordinary merit. The Silver-spangled were more or less out of condition, but the Pencilled, which were of both colours, were exceedingly good. The first-prize birds were Golden, as nearly as possible faultless, and the second prize went to Silvers. The piece of plate for Hamburghs was awarded here. In the "Variety" class Crêve-Coeurs were first, and Silver Polands second, both pens being very good; the cock in the first-prize pen was such as is seldom equalled.

All the *Bantam* classes were large, but many of the birds would have been quite as well on their walks. In Black Red Game the winners were very good, and were the only pens that were placed at a disadvantage as to light. In the "Variety" class, Piles won both prizes, the first-prize pens being chickens of extraordinary merit, and the piece of plate was won by them. In the Bantams, any other variety, Blacks were first and Japanese second. Among single cocks, Black Red Game was first, and a pure Silver Sebright second.

The Aylesbury and Rouen *Ducks* were good. The piece of

plate went to Rouens; but in the "Variety" class many of the pens were empty at the time the awards were made. In both the selling and cottagers' classes many good specimens were shown, more particularly in the latter class.

In *Pigeons* the competition was very close in most of the classes, that for Fantails being such as is rarely excelled, although with one exception there was nothing of note in the Nuns, and the timepiece was awarded to the Fantails. Pouters and Jacobins competed together for a piece of plate, which was won by a capital pen of Reds of the latter variety. The Pouters were neither in good show nor clean, except the second-prize birds, which were very runtish in appearance. Turbits were not so good as we usually find at Melrose, though the first-prize Yellows were very good. The English Owls were good throughout, and won the cup from the Turbits. Tumblers made a close run for the position. Two excellent pens of Almonds divided the honours, and the "Variety" class gave evident proof of the need of revision of the schedule, no less than eleven different varieties competing.

There was a nice show of cage birds, but the entries were not numerous.

DORKINGS.—1 and Cup, J. W. Will, Errol. 2, D. Hardie, Priesthaugh, Hawick *hc*, D. Hardie; T. Raines, Stirling; D. W. Gellatly, Meigle; T. H. Heys.

DORKINGS.—*Chickens.*—1 and *hc*, T. Raines. 2, D. Hardie. *c*, Miss Milne, Otterburn.

SPANISH.—1, D. Waugh, Melrose. 2, H. Wilkinson, Earby, Skipton. *hc*, D. Waugh; R. Dickie, Burnside, Alva, Stirling. *c*, J. Tbresh, Bradford.

COCHIN-CHINA.—1 and Cup, J. W. Will. 2, J. W. Taylor, Low Mills, Ulverstone. *hc*, J. Jamieson, Jedburgh; R. Reid, Hollenhirst, Canonbie; E. Fearon, Whitehaven.

BRAHMA POOTRA.—1, R. Brownlie, Townsend, Kirkcaldy. 2, T. Raines. *hc*, J. W. Will; J. W. Brockbank, The Croft, Kirksanton.

GAME.—1, J. Brough, Carlisle. 2, J. W Will. *hc*, R. Little, Dilkatree, Longtown; J. Campbell, Langholm; S. M'Coll, Glasgow.

GAME (Any variety).—*Cock.*—1 and Cup, J. W. Will. 2, J. Brough. *hc*, A. Dewar, Linton, Cluny, Aberheen. *c*, W. Scott, Jedburgh.

HAMBURGHS (Golden-spangled).—1, R. Dickson, Selkirk. 2, R. H. Ashton, Mottram, Manchester. *hc*, J. W. Will. *c*, Mrs. B. Sweeten, Penrith.

HAMBURGHS (Silver-spangled).—1, W. R. Park, Abbotsmeadow, Melrose. 2, Ashton & Booth, Broadbottom, Mottram. *hc*, J. W. Will.

HAMBURGHS (Gold or Silver-pencilled).—1 and Cup, W. R. Park. 2, J. Webster, Weirgate, Killbrook, West Colne. *hc*, W. Clayton, Keighley; J. W. Will; W. Linton, Selkirk; D. Cheyne, Cowpen; R. Dickson, Selkirk.

GAME BANTAMS (Black Red).—1, D. Hardie. 2, A. Hutton, Carolside, Earlston. *hc*, T. Raines; W. Rogers, Sunderland; R. Brownlie, Townsend, Kirkcaldy. *c*, G. M'Millan, Jedburgh; Miss J. M. Frew, Sinclairton, Kirkcaldy.

GAME BANTAMS (Any other variety).—1 and Cup, R. Brownlie. 2, J. Archibald, Earlston (Pile). *hc*, J. Robson, Bishop Auckland; J. W. Brockbank, Kirksanton (Duckwing); W. Bogie, Melrose (Brown Red).

BANTAMS (Any variety).—Cup, R. H. Ashton (Black). 2, J. Archibald (Japanese). *hc*, W. H. Robinson, Long Lee, Keighley (Black); T. Watson, Freeland, Bridge of Earn (Silver (Sebright); R. H. Ashton (Black); Master A. Frew, Sinclairton, Kirkcaldy; Lord Polwarth, Mertoun. *c*, R. Frew; Miss B. P. Frew.

BANTAMS (Any variety).—*Cock.*—Cup, R. Brownlie, Kirkcaldy (Black Red). 2, A. Johnstone, Bathgate (Silver-laced). *hc*, H. H. Thomson, The Oaks, Sunderland (Black Red) (2); J. Bone, Craigaford, Earlston (Japanese); R. Brownlie, Kirkcaldy (Pile).

DUCKS (Aylesbury).—1 and 2, D. Hardie, Priesthaugh, Hawick. *hc*, G. Dryden, Selkirk; J. Brodie, Pahacehill; C. Little, Woodhouselees Smithy, Canonbie.

DUCKS (Rouen).—1, Cup, 2, and *c*, D. Hardie. *hc*, H. Stephenson, Lillyford.

DUCKS (Any other variety).—1 and 2, R. H. Ashton. *c*, Lord Polwarth, Mertoun.

ANY OTHER VARIETY.—1 and Plate, W. R. Park (Crève-Cœur). 2, W. Bearpark, Ainderby Steeple, Northallerton (Silver Polands). *hc*, J. F. Fawcett.

SELLING CLASS.—1, W. Linton, Selkirk (Crève-Cœur). 2, D. Hardie (Dark Dorkings). *hc*, R. H. Ashton; A. Steele, Kelso (Dorkings); W. R. Park (Silver-spangled). *c*, J. W. Will.

COTTAGERS' CLASS.—1 and Timepiece, Mrs. Waugh, Melrose (Spanish). 2, G. Mitchell, Keighley (Silver-spangled Hamburgh). *hc*, J. Beattie, Kirk, Selkirk (Brahma Pootra); R. Mason, Barrhead (Dorkings); W. Linton, Selkirk (Golden-pencilled Hamburgh).

TURKEYS.—Plate, D. Hardie. 2, J. Anderson, Friarshall, Melrose. *hc*, Lord Polwarth.

PIGEONS.

FANTAILS.—1 and Timepiece, J. F. Loversidge, Newark-on-Trent. 2, M. Crosbie, Abbotsmeadow. Equal 2, A. Johnstone, Bathgate. *hc*, Miss J. Thomson, Fernhill, Bingley; J. F. Loversidge. *c*, J. W. Watson, Bradford; H. Yardley, Birmingham.

NUNS.—1, J. Turnbull, Melrose. 2, H. Scott, Gattonside. *hc*, G. Imrie, Bourtree, Ayr. *c*, T. Honeyman, Melrose; T. Lockhart, Kirkcaldy; J. Walker.

POUTERS.—1, M'Gill Skinner, Edinburgh. 2, H. Yardley. *hc*, F. M'Crae, Aberdeen; M'Gill Skinner.

JACOBINS.—1 and Plate, Miss J. Thomson. 2, H. Yardley. *hc*, Miss R. C. Frew.

TURBITS.—1, J. W. Watson. 2, M. Crosbie. *hc*, A. C. Laug, Selkirk; W. Goddard, London; H. Yardley.

OWLS (English).—1 and Plate, M. Crosbie. 2, W. Goddard, London. *hc*, J. Turnbull; E. Paterson.

TUMBLERS.—1, A. Johnstone. 2, W. Goddard. *hc*, W. Brydone, Lanton Mains, Dunse; F. M'Crae; J. W. Watson; H. Yardley. *c*, M'Gill Skinner.

ANY OTHER VARIETY.—1 and Plate, M. Crosbie (Letz). 2, H. Yardley. *hc*, Miss J. Thomson (Carriers); J. Webster (Dragoons); J. Turnbull (Trumpeters); W. Goddard (Carriers and Frillbacks); M. Crosbie (Black Swallows). *c*, Miss J. Thomson; A. Johnstone; J. Fawcett.

SELLING CLASS.—1 and 2, M. Crosbie.

CAGE BIRDS.

DONS (Yellow).—1, R. Hunter, Galashiels. 2, J. Hardie, Galashiels. *hc*, W. Turnbull; Miss Isaac, Melrose.

DONS (Buff).—1, R. Hunter. 2, J. Hardie. *hc*, G. Park, Galashiels. *c*, A. M'Lean, Melrose.

FLECKED (Yellow).—1, R. Hunter. 2 and *hc*, T. Wilson, Hawick.

FLECKED DON (Buff).—1, G. Park. 2, T. Wilson, Hawick. *hc*, W. Bogie. *c*, R. Hunter.

CAGE BIRD.—1 and *c*, R. Paterson. 2, J. Crawford, Melrose. *hc*, W. Douglas.

CANARY (Common).—1 and 2, W. Hatton, Purdon's Crook. *hc*, E. Waugh, Melrose.

The Judge was Mr. E. Hutton, Pudsey, Leeds.

GERMAN BEE-KEEPERS' CONVENTION.—At the seventeenth annual meeting of German bee-keepers held in the city of Kiel, in Holstein, Salzburgh in Bavaria was chosen as the place of meeting in 1872. The city of Halle was named as a desirable place for the meeting of 1873.

CRYSTAL PALACE BIRD SHOW.

IN RE FAST COLOURS—EXTRAORDINARY PROCEEDINGS.

I FEEL almost inclined to dismiss the Norwich classes without further comment than I made in my necessarily brief notice of last week. The champion birds of the season have held pretty much the same relative positions throughout, subject occasionally to some slight variation according to the ideas of different Judges. Quality will always find its way to the front, and it must have been gratifying to many exhibitors, who have supported nearly all the minor meetings of the year, to find that their public running has been no fluke, but that in the great race they have run very forward, and in not a few instances have distinguished themselves by graduating in high honours.

But I cannot conscientiously pass on from this deservedly admired class of birds without adverting to some circumstances with which the great Show of 1872 will be ever associated. And I the more readily approach the matter because I am to some extent concerned in it. Any shirking of the question would be pusillanimous, while a ventilation of the subject will be for the best interests of a fancy whose growing claims are acknowledged by an ever-widening circle of admirers. Almost every year sees some secession from the ranks, though fresh recruits are always found to fill the vacancies. Causes beyond our ken affect many. They retire, we don't know why, but they retire from the field. Death removes others, and the name of at least one veteran is missing from our catalogue this year. His mantle, however, seems to have fallen on his sons, and it is only for them to emulate their father to leave behind them a good name. But the main cause of defection is the unpleasant conviction forced upon the minds of some that "things are not what they seem," a truism, of which a practical exemplification is by no means rare. I could point to more than one, or two, or three who can tell of long prices freely paid for birds with first-class diplomas, which, in many instances (unfortunately in the case of one buyer in *every* instance), turned out impostors of greater or less degree. I cast no reflections on the exhibitors of these birds. Many of them know how birds which they thought perfection turned out the succeeding year, and have explained how they had been made victims of misplaced confidence. And here let me say in passing, how much it behoves every gentleman to carefully examine every specimen which represents perfection, and upon which, its exhibition career being over, he places such a selling price as renders its falling into the hands of a fresh owner highly probable. To find evenly marked birds growing a dark feather on one side of the tail, or a black feather on the shoulder or in the wing, or as many ticks in the back as make a respectable saddle, or to find the cap of a Lizard with a blemish as large as a split pea, or the tail of a Cinnamon growing white feathers where white feathers never grew before, or to hear supposed hens singing lustily, are matters as disagreeable to the seller as the buyer, and, in the case of sensitive minds, eventuate in conclusions by no means conducive to a pleasant state of things.

I am aware these irregularities are not confined to our fancy alone. The "Poultry Chronicle," records of a pursuit essentially English in its character, one of the hobbies peculiarly pertaining to the country gentleman, and graced by the name of many a high-born dame, teem with iniquities which must bring the flush of indignation to the cheek of many of its supporters.

But let us hope that these disagreeables are the remains of an erroneous belief as to right and wrong which, if nothing else will eradicate it, will have to take its fight with those scoundrels who practise its formularies. It is but a faint hope, for my simple conviction is that the whole guild of painters, stainers, tailors, and doctors, in general constitute a section of society which, under a more genial sun, would develope itself into candidates for the treadmill.

I am led to these remarks from the fact of there having been at the late Show some birds which general opinion pronounced to be artificially coloured. There were two Clear Jonques, one Clear Buff, one or two Variegated Jonques, one or two Unevenly Marked Jonques, and four Unevenly Marked Buff. Eight of these birds I exhibited myself at a show which was held here in Sunderland in Christmas week, and thereby hangs a tale! Previous to Cheltenham Show I received a letter from a gentleman residing in one of the midland counties, whose opinion is entitled to the greatest respect, in which, among other matters, he referred to some painted Norwich and Lizards' caps which had come under his notice, and which he said I was to look out for, as I should certainly come across them. Further information I had none, other than some clue as to the whereabouts of these birds, which he remarked jestingly were "creditably" done. How many had been seen, or whether Jonques or Mealy, Clear or Variegated, did not transpire. At Cheltenham I met an extraordinary bird in one

class, to which I awarded the first prize. One of the most noted exhibitors of that class of bird, a man whose opinion is law, and who has carried off several firsts at the Palace this year, was present, and said to me in a friendly way, "Have you not made a mistake with No. ——? My bird beats it out of sight." I knew that upon bringing both to the light he would think differently, and upon doing so he simply said, "I'm satisfied," and there was an end of the matter. Several times during the Show was this bird an object of attraction and curiosity, for the meal *over* the colour was something remarkable. On the second day of the Show I received a letter from my midland county friend, to say he thought No. —— was "one of the lot;" but I was so satisfied about it, and was so supported by the opinions expressed, that on my return home I wrote to the person in whose name it was entered with a view to buying it, but was informed in reply that he had sold it to the person in whose name it and the others appeared at the late Show. Next I had a letter from the holder of these birds to say he had some remarkably fine Norwich birds, the best ever seen in that part of the country, and if I would like a pair he would keep me some, to be delivered after the Palace Show. One letter led to another, and in course of correspondence he said some of these birds had been thrown out at ——, but that the Committee had been over, and upon further examination, and also having seen a portion of them half moulted, had come to the conclusion they were genuine and had tried to buy them. The *reason* of this wish to purchase and the refusal to sell I have since had explained. My midland friend with whom I "shed a tear" at the Palace said, "£10 for four birds was an expensive experiment!" There began my knowledge of the existence of these birds, and my acquaintance with them being limited to the single specimen I had seen at Cheltenham, and the plausible statement made by the present holder.

And now for the story of my exhibiting them. Since I have acted as Judge I have never been an exhibitor, and only once have I ever judged over a bird which had been previously my property, and it was nowhere. But a knot of fanciers who constitute one of the oldest clubs in this town projected a show for Christmas week, and from their rules and regulations expunged the *bonâ-fide* property clause. I have always maintained this rule is sound in principle, but a majority of the Committee of the old Sunderland Ornithological Society thinking it was prejudicial in its action, eliminated it from their thirteenth annual Exhibition. The "fancy" is not young here. On consulting the Secretary I found the rule was omitted purposely, under the belief that it would assist the entries, or, at least, enable any home combination to compete against a foreign confederacy, against which there is no safeguard. This being the case, I intimated my intention of competing for the silver cup, which was one of the attractions of their schedule, and for this purpose borrowed as many birds as I could, and among them these peculiar Norwich, one portion of which arrived the night before, and the remainder before daylight on the morning of the Show. By gaslight they looked—never mind how they looked, but by daylight they looked just exactly as the owner had described them, such as never had been seen "in that part of the country." I was going to say, nor in any oth——, but I should be sorry to cast any reflection on what was, perhaps, a kind intention. When I got a good look at them, I told one of the Committee who was a personal friend of mine, and who had seen the whole of the correspondence, that if the Judges suspected the genuineness of the birds I would like to be sent for that there might be a thorough examination. However, they apparently saw no reason to disqualify them, and the Clear Jonque stood first in its class, and one of the Variegated Jonques first in its class, the Buff birds coming in for a share of commendations. But one of the rules (one which I wrote for our own Society, and which I little dreamt would first be applied in my own case), stated that if clear proof be given that any bird has been fraudulently dealt with, the Judge's decision shall be null and void. And I think it is a good rule, for there are cases in which no mortal eye can detect a fraud, such as the extraction of a single dark feather from the head or back, or any other part, which would convert a Ticked bird, a Mule for instance, into a Clear one, a transformation the value of which is great. Acting on this rule the Committee subjected these birds to an ordeal in which, I think, their zeal rather outran their judgment, and in a way which was hardly constitutional, inasmuch as I was not made aware of what was going on, and only arrived at a knowledge of the fact from finding the Clear Jonque with a tail such as is not usually found on a bird, and being presented with a handkerchief which was alleged to contain colouring matter extracted from the delinquent specimens. As for the existence of colouring matter on the handkerchief, truth compels me to say that neither could I, nor any one person out of at least a score who examined it, find any trace. There was certainly a slight smear of something, a very slight smear, but nothing more than a tinge which can be got from the tail of any bird not absolutely clean, and which is simply the dried excrement which it takes up from the bottom of the cage. This I mention only as the expression of my decided conviction, that such was the character of the smear, if smear it could be called (for subsequent examination conclusively demonstrated the impossibility of discharging colour even by subtle appliances), and not as any expression of opinion as to the fact of the birds not being stained. That I will come to now, and it is the most serious part of the business. From this point I am done with the birds so far as regards being connected with them. Perhaps it was a mistake for me even to have put them on the stages. I think it was.

What I have further to add is by far the most important part of the matter. After the close of the Show I submitted the suspected birds to a skilled analytical chemist, and the result of a two-days analysis was a certificate to the effect that he could detect no trace of any pigment or foreign colouring matter whatever. I know also that they have been tried in many ways by different Judges, but always with the same want of success. Nothing comes off. If I am asked what is my candid opinion of them, I unhesitatingly say I am impelled to the belief that they are artificially coloured. *Fiat justitia, ruat cœlum.* When I say *they*, I mean specially the Jonques, Clear and Variegated. I am not so sceptical about the Buffs, two of which (Variegated) were highly commended by the Judges at Sydenham, though the Clear Buff was ignored. I can conceive the possibility of being able to stain a yellow bird, but by what process of legerdemain a Mealy bird can be dyed, at the same time retaining the meal, I cannot divine. I had some conversation with Mr. Barnesby on the subject. I believe he thinks it perfectly feasible, and showed me some samples of artificially coloured feathers. But they were the large quill feathers of either poultry or Pigeons, were not dyed jonque nor any approximation to it, nor did they show a mealy edge. It is a simple thing to operate on a single large feather; but bearing in mind that the colour on the small feather of a Canary lies on the extremity of the web, which in a Mealy bird is edged with a tiny fringe of white, and further, that it is the close overlapping of the feathers and the projecting of the edges like the scales of a fish, only in a less degree, which produce a uniform shade, it must be next door to an impossibility to colour the entire surface of a bird's plumage and then discharge the colouring matter from the extreme edge of the feathers in such a way as to produce the mealy appearance which is the striking feature in what are recognised as Buff birds. If that can be done, the mystery of the man in the iron mask, the squaring of the circle, the theory of perpetual motion, and the settlement of the Alabama claims, are problems easy of solution.

I believe that hitherto these birds have defied all attempts to discharge foreign colouring matter from them, and here we are treading on most unpleasant ground. A correspondent, a man of education (not the sort of man who carries a mysterious 2-oz. phial in his pocket, and shaking it up assures you, with one eye closed, apparently diving into the mysterious recesses of his brain, and the other winking at some familiar far-off in space, that "this will fetch it off") writes me, "I am sorry you exhibited them, the analyst's certificate notwithstanding, for anything *he* could find had done its work and gone." Is the art of staining birds so that the skill of the analyst is powerless before the knavery of the dyer a *fait accompli?* Is it only when there are too many eggs in the pudding that epicures find fault with the cooking? Can it possibly be that others of these marvellous yellow birds are doctored, and that it is only when some knave cleverer and more enterprising than his fellows ventures to introduce a new shade that his wares are turned out of the market? If it be possible to fix one colour in defiance of every known solvent, why not another? What guarantee is there that our Lizards are not blackened-up and polished, *their caps burnished* (*verb. sap.*), our Cinnamons bronzed, our evenly-marked Canaries and Mules manufactured to order, our Clear Mules bleached, and that half of the whole business is not a sham?

The art of plucking and trimming pales before this new science, which baffles the erudition that can discover a world of existence in a drop of water, can extract from the fœtid oils of gas tar dyes rivalling in brilliancy the hues of the rainbow, or produce eau-de-millefleurs from the drainage of our cow byres. Henceforth the scissors, tweezers, and surgical instruments must give away to the cunning workers in colours.

There is but one cure for this double-dyed scoundrelism. An ardent fancier suggested it to me at the Palace, though I had to some extent anticipated it in the rules of the Cheltenham Show. It is that every suspected bird should be impounded, *nolens volens*, at the will of the executive, and, if proved to be an impostor, the owner should be anything you like—lynched. But proving the fraud is the difficulty. I have had no end of receipts prescribed; liquids, solids, gases, acids, alkalis, from stuff that was warranted to change the skin of an Ethiopian down to the gentle persuasives hidden under cabalistic signs which find no parallel in Fownes, which would "fetch it off" like "snow from a dyke back."

Before dismissing this unpleasant subject I will just say that the reputed owner of these birds is an entire stranger to me. I never saw him till, as I was hurrying down to the train on the

evening of the second day of the Show, I identified a travelling cage coming up the long corridor. I had only time to express a hurried but decided opinion on the birds, in reply to which he asserted he had not bred them himself, they were not stained, and the old story, "they had got nothing off." Nothing can be easier than to prove the first proposition, while on the proof of the second hangs the reputation of the exhibitor. The *onus probandi* lies in a nutshell.

Of Belgians there was a large entry, no less than fifty. I felt satisfied that the amended classification, which included the Clear and Ticked birds in one division, would result in greater numbers being staged. I commenced my examination of the long chain of upwards of a thousand links at either end, and I regret that the limited time at my disposal did not allow of my making that minute inspection of these classes which would warrant my offering other than general remarks upon this most extraordinary Canary. The names of the winning competitors as given in the return of last week, the fact that, in a group of twenty-one, thirteen were deemed worthy of honourable notice, and the whole specially mentioned as forming a very superior class, speak volumes.

I was delighted to see such a muster of "London Fancies." What a pity it is that this *rara avis* is not more cultivated. Anything more beautiful than a first-class specimen of this marvel of Nature it would be hard to find among the varied feathered favourites of our aviaries. I can well understand the conservatism of its admirers, though, like other conservatives, they hail with satisfaction true progress. Mr. Hooke, the Secretary of the London Fancy Club, went over the birds with me, Mr. Waller too, and Mr. McMillin, hardy old veterans, still dark in the stalk though grizzled in the web through repeated moulting, dropped a little of their ancient lore, and a treat it is to sit at the feet of such Gamaliels. Neither of these gentlemen, however, figured as exhibitors this year, an epidemic having decimated their stock and reduced them to the verge of bankruptcy. Deeply wedded are they to the bird they have made a life-long study. The Bank of England may break, the expected comet may come into collision with us, but their motto will ever be, Vivat *the* Fancy! As a whole the Fancies were not up to the standard of previous years, but to look too long at the winning Mealies was to engender a spirit of covetousness.

A great Lizard fancier who name usually figures in the van said to me, "If you send any notice to the Journal say the Lizards were a lot of duffers." That, of course, includes his own. Assuming "duffers" to be a legitimate substantive, from it we get an adjective expressive of the condition of the first-prize Golden-spangled bird. It certainly was in duffing condition, its right wing in particular. It looked as if it had been in the tub, and was all in a heap. A few hours' change of temperature, however, will soon transform a blooming bird into a thing not like itself at all. I had a commission to claim a bird in this class, "but not at ruinous prices." My affections halted between 442, Smith and Preen, and 444, Mr. J. N. Harrison, second and third respectively. I think I should have been disposed to put each up a step. There have been few shows since Whitby at which these champions have not measured swords together, the same two birds always doing battle for the Coventry firm who have brought them out from first to last in the perfection of condition. No. 440, Mr. T. W. Fairbrass, was superbly spangled but defective in cap, and well merited its very high commendation. In this class were two birds with most miraculous caps, so miraculous, indeed, that the Judges evidently doubted their genuineness. I am told I once gave one of them either a highly commended or a commended. If so, I do repent me in sackcloth and ashes. My midland county friend's comment on them was "All in the same swim!" I wonder what he meant? An extract from an unpublished manuscript in my possession reads, "Mr. Blakston know no more about a bird nor a bird know about him!" For a solution of this enigma put this and that together.—W. A. Blakston.

(To be continued.)

NOTES ON BEES.

Having been much absent from home during the last six or seven weeks, and otherwise much engaged, I have been unable to notice various remarks of correspondents of "our Journal" which have appeared in its pages from time to time in the interval. I will now endeavour to make up lee-way by venturing a few observations on Mr. Lowe's paper on "Wintering Bees," page 25 of the current volume.

I observe, first, that while he "does not recommend wintering our bees either in cold, dry, dark cellars, or in burying pits," he has nevertheless given an array of names, including the most eminent bee-keepers of modern times, who have adopted one or other of the modes alluded to "with great success." He tells us that "the celebrated Dzierzon usually winters some of his weaker colonies in dry cellars and they always do well." I will merely remark, therefore, that I hope some of our apiarian friends will not have been deterred by Mr. Lowe's dissuasive from trying the plan of wintering which I ventured to recommend in December last. "Strong stocks," as I said, "are best left to themselves on their summer stances;" but in the case of weak hives, which would certainly have perished in such situations, it is worth trying whether Mr. Hosmer's plan be not a feasible one, and likely to prove a success in this country as well as in America; for, be it observed, that while Mr. Lowe speaks of Mr. Hosmer's theory as "erroneous in principle and entirely delusive," that gentleman assures us that what he recommends is not "theory," but the result of experience.

With regard to "summer-bred" bees my opinion tallies in the main with that of Mr. Lowe. They are probably all gone in active stocks by the middle of November; but surely it is possible, as it is certainly very desirable, to supply their place in rapid succession late in the autumn with a younger and more vigorous generation, and this can always be done by encouraging late breeding. It is just when breeding is going on most vigorously that the succession of population in a hive is most rapid, and then it is that the "old bees" (autumn-bred if you like) are soonest got rid of, and their places supplied by a younger generation, who will live on later into the spring, and help on with better success the early prosperity of the stock. Therefore I do maintain that it is desirable to get rid of summer or early-autumn-bred bees, that it can be done in the way indicated, and in so doing we do not weaken, but on the contrary decidedly strengthen the stock which may be thus treated, and put it into a more favourable condition for early spring progress. If, on the other hand, from any cause late breeding has been discouraged, the hive, being in a state of torpidity, maintains a much larger proportion of old bees, which will live the longer in proportion as they remain at home, and die off in their early spring flights, to the great injury of the stock, owing to the smaller number of young bees it contains than in cases where late breeding has occurred.

Should any of your apiarian readers have made trial perchance of such a mode of wintering their bees, I should be glad to hear with what result. I would gladly have tried it myself if I had had a proper place in which to stow away my hives, for I never had so many weak hives at any period of my bee-keeping life, nor have I ever had so great a mortality. Out of nineteen stocks, eight have died this winter, some from dysentary, others from starvation during my absence from home.—B. & W.

OUR LETTER BOX.

Dorkings Dying (*Lady Subscriber*).—You would render our task easier if you gave us some idea of the run your fowls have, and also the manner in which they are fed. From the fact of their falling ill in the autumn, which is their weakest time, we imagine they are in low condition, and unable to meet the change of atmosphere that takes place at that season. The long rainy time we have had may have taken the same effect now at an earlier period. The condition of the liver you mention is generally caused either by over or injudicious feeding, or by bad roosting places. We have never found it infectious, but where the management was at fault all the fowls in a yard were similarly affected. Bad water is very injurious to fowls, yet they prefer it to any other. Another information is so scanty we will tell you what you should do, and you will then, perhaps, be able to see the cause of your misfortune. The fowls should roost in a dry house or shed completely sheltered from draughts. They should have perches not more than 2 feet from the ground. The floor of the house should be earth, no brick, board, or stone. The food should consist of barleymeal or ground oats soaked with water morning and evening, with a meal of whole corn at midday. This is all they require if they have a grass run. If they have not, you must supply them with green food, sods of earth covered with growing grass, and grit for a dust bath. In any case they must be provided with lime; bricklayers' rubbish is the best. The treatment for the present malady will be pills of camphor, one the size of a garden pea morning and evening. If this will not cure, try Baily's pills. Hinder them, if possible, from drinking dirty stagnant water.

Game Hen not Laying (*Nine-years Subscriber*).—The fact of her avoiding the cock would have nothing to do with her laying, as one is quite independent of the other. Did she come in the basket alone, or was there a cock with her? These things sometimes happen in travelling. Examine her: you will likely find some injury to the back, or it may be there is inflammation of the egg-passages. It is against all rule and precedent for a young hen not to lay if she be at liberty, and we hardly believe in such a case. She may steal her nest, or eat her eggs, or they may be eaten for her, but we believe she lays. In confinement it is somewhat different, and is just possible. The drooping of the wings is a plain indication that something is wrong. We advise that you give castor oil freely, a table-spoonful for a dose, and that you also take a wing-weather and having stripped the lower part near the quill, saturate it thoroughly with castor oil, and pass it down the egg-passage as far as you can. If you repeat this a few times we believe you will find it a beneficial treatment.

Brahma Cock Wheezing (*D. J.*).—Give him a good dose of castor oil, and before you do so put a feather down his throat. He is suffering from the wet weather. Give him two pills of camphor each the size of a garden pea.

Rendering a Hen Broody (*An Amateur*).—We know no justifiable method of making a hen broody; people are, as a rule, far more anxious to prevent them from being so. The old abominable way of trying to make a hen sit, was to pluck all the feathers from her breast, and then whip it with stinging

nettles, or rub it with ointment producing painful itching, to alleviate which she used to press hard down on the cold eggs.

REDCAPS (*An Amateur*).—The last "Redcaps" we saw were at Sheffield; there was a class for them some years ago at that Show. These were so little known to ordinary Judges, that special Judges officiated for them. If we recollect aright, Mr. Halliday bred them in that town.

FOWLS IN CONFINED SPACE (*Nemo*).—You may keep twenty fowls easily in the space, 50 yards by 2 yards. We think Brahmas would suit you best. A 4-feet fence will keep them in, and we think wire the cheapest, because when taken down it cannot be used for firewood. When you have chickens they should go into the kitchen garden. If it is not already done, part of the space you have should be laid down in grass.

PINIONING MANDARIN AND CAROLINA DUCKS (*W. R.*).—These birds cannot be properly kept unless they are pinioned; therefore, it would not disqualify them for exhibiting. It is said a gipsy may be kept tame till he comes in contact with other gipsies, when he immediately joins them, and it is so with every description of wild fowl. You may hatch them from eggs and have them so tame that they will come to your whistle to be fed, and will be your delight all the summer; but when winter comes, and the wild birds are in the air, when they settle among the tame birds in the night, and prepare to leave in the morning, all the tameness disappears, and unless the birds are pinioned they go with the new comers. It would be impossible to exhibit full-winged birds in cages, as when frightened they would fly up and seriously injure themselves. Tameness is greatly induced by the inability to fly. A full-winged bird shut in an aviary covered at top never becomes perfectly tame, but on every occasion beats and dashes himself about; while a pinioned one, after some few attempts at flying, finds it impossible and accepts the situation.

EGG-PRODUCING HAMBURGHS (*F. S. H.*).—There is no difference in properties. Both are equally good layers. If it is near a town the white of the Hamburghs gets sooty, while the Golden do not show it so much. We have a prejudice in favour of the Golden, but we should be troubled to justify it.

GROUND OATS (*J. H.*).—Ground oats are so skilfully prepared in Sussex, that although nothing of any kind is taken from them, not even the husk, they are reduced to so fine flour that they might easily be made into fine paste. It is the fact that the meal contains the whole of the corn, which makes it so nutritious. Fowls have an aversion to very coarse food, and ordinary ground oats when mixed with water have the appearance of sawdust and bran mixed. Often they will not eat it, and we know that Mr. Baily, no mean authority, has given up grinding oats, and buys them in Sussex. In his opinion the bran of wheat is advisable only for animals that have teeth.

JUDICIAL DECISIONS (*W. M. Mann*).—All that you state is not inconsistent with correct judging. The health of fowls, and other circumstances at the time of judging must be known before the awards can be pronounced erroneous.

WHITEHAVEN POULTRY SHOW.—We have letters from Mr. Rollinson and Mr. Lord denying that they trimmed their birds. They must discuss the subject with the Committee, and we will readily publish the result.

DUBLIN POULTRY SHOW (*Reporter*).—We omitted the names merely because they were in the prize list, and we do so always as far as possible to economise space. You inserted the names evidently impartially.

PORTSMOUTH POULTRY SHOW.—The address of Mr. R. Wilkinson who took the second prize for Spangled Hamburghs at this Show, is Waterden Road, Guildford, not Portsea, as printed at page 160. (*T. A. D.*).—Write to the Secretary and ask him to return you postage stamps to the amount you claim. He ought not to have retained the money for the catalogue and yet neglect to send it; but allowances ought to be made for the pressure of business on the Secretary at the show time.

BIRMINGHAM POULTRY SHOW.—A pen of Aylesbury Ducks exhibited at the last show by the Rev. G. Gilbert, of Claxton, Norwich, were highly commended. This was omitted in the prize list by accident.—J. B. LYTHALL, *Sec.*

ALMOND TUMBLERS (*A. Atkins*).—It is in No. 489.

DRAGOON'S EYES (*B. G. S.*).—Get some fuller's earth, make it into a paste with water and put it on the eye, and it will cure it very soon.

FANTAILS AT WOLVERHAMPTON SHOW.—Mr. W. Choyce's and not Mr. Loveridge's pen of Fantails was highly commended.

BARBS AT WOLVERHAMPTON.—"If 'CURIOUS' will give his name and address, I will give him the information that he requires, as I object to anonymous correspondents.—B. R. WRIGHT."

LIGURIAN BEES (*W. C. C.*).—We know of no separate work on their management. We do not think you can do better than apply to Messrs. Neighbour.

QUEEN BEE DEAD (*Jane*).—A lost queen bee at this time of year cannot be replaced. The earliest period at which one could be procured would be towards the end of April. We fear your case is beyond recovery. However, we put your appeal in print. "A lady will be extremely obliged if any kind bee-keeper will send her a queen, for which she will be glad to pay what is asked. The name and address is at the office of this Journal."

BEE MANAGEMENT (*E. M. M.*).—It is not necessary to cut out old comb every season, but the hives should be examined early every spring, and any black, mouldy, or misshapen combs should be cut out. We advise you to do this with yours. It is advisable also to cut away any drone comb which appears to be in excess in the central parts of the hive. To repair old hives of straw appears to us to be useless. Better commit them to the manure heap or the fire. Boxes can be repaired if necessary with the same material.

HIVE PERISHING (*W. J. H.*).—The comb you sent was quite empty, and the accompanying bees were in a stinking condition. There is little doubt that the bees perished of starvation, and have been dead for some time.—EDS.

PRESERVING RABBIT SKINS (*G. R.*).—When the rabbit skins are cleared of all fatty particles that may remain, nail them fur-side downwards upon a board, stretching them to their full extent, and tack them down; then wash them with a solution of 1 oz. of saltpetre to a quart of water twice a-week, and generally three applications will render them fit for use. When removed from the board, roll them up a few times, and they will become soft and flexible. Tanning is resorted to, but is more expensive, and is the work of the furriers or leather-dressers.

CANNIBAL CANARY (*W. Sage*).—The egg-eating propensity is a thing no one can understand. There is no radical cure for it. You may try the experiment of filling an empty shell with cayenne pepper, but the probability is, she will eat the shell and its contents. You are beginning to breed a little too soon. Give the hen a rest, and in the meantime supply her with plenty of shell-producing material in the shape of old lime rubbish.—W. A. BLAKSTON.

ZEBRA LOVE BIRDS (*Edith*).—There are no Zebra Love Birds, the Australian Grass Parrakeets are probably meant. They moult irregularly here, our summer is their winter season. They breed, and even hive out of doors freely in England. They rest in a hole in a tree like other Parrots, and Hawkin sells cocoa-nut nests for them to build or lay in, if placed in a cage. None of the other foreign Finches, &c., mentioned, breed in this climate in confinement.—C. H. F.

TEACHING CANARIES TO PIPE (*A. H. B.*).—I have never attempted the task of teaching any bird to pipe, but the usual way is to begin with a young nestling, which must be confined in the dark or covered up in such a way as to give him little opportunity of having his attention taken off by surrounding objects. If you are a good whistler you can pipe the melody yourself, which should be simple and always whistled from beginning to end without a stop. This occupation is at once delightfully monotonous and well calculated to develope the virtue of patience, at the same time making your family well acquainted with the musical phrases in "The Blue Bells of Scotland," "Over the Water to Charlie," and other melodies in which Bullfinches, Starlings, and other piping birds delight. If you have not confidence in your own musical ability, purchase a bird-organ, which can be had of any musical instrument dealer. You can then take a time at the crank every morning after your breakfast, but before the bird has had his, and when you find he makes a response to your music reward him with a grain or two of hempseed or any delicacy, and leave him a while to study. Repeat the lesson at frequent intervals during the day, and when tired of the crank get somebody else to take a turn. If you persevere with this plan, the prisoner may learn to pipe—or he may not.—W. A. BLAKSTON.

REMARKS.

14th.—Dark and foggy morning, cloudless for a few hours about noon, and nearly so at night with bright moonlight.

15th.—Overcast almost throughout the day, the only exception being a few gleams of sunshine in the forenoon.

16th.—Overcast with northerly wind and no sun.

17th.—White frost in the morning, and very fine till noon, when it clouded over, and between 3 and 4 P.M. slight rain fell, but most of the rain recorded for this day fell after midnight.

18th.—Rain in early morning, and rather dull all day.

19th.—A few minutes after midnight (0.10 A.M.), a sharp squall from S.W. with heavy rain, and it is reported some hail. The day was fine and sunny. Fine lunar halo for several hours at night.

20th.—Bright fine day, white frost in morning, fine evening.

The week has been slightly cooler than the three previous weeks, but the temperature is, nevertheless, considerably warmer than the average. The temperature in the sun on the 20th was higher than had yet been reached this year.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 21.

THERE is scarcely any alteration to report. Large quantities of rough vegetables come into the market, and the supply of Broccoli from the west of England and the Channel Islands is almost unprecedented at this season. Forced Asparagus, Sea-kale, and Dwarf Kidney Beans are all ample for the demand. French Asparagus is coming in good, but the sale is heavy at prices ranging from 12s. to 18s. per bundle.

From observations taken near London during forty-three years, the average day temperature of the week is 48.7°; and its night temperature 32.9° The greatest heat was 70°, on the 4th, 1860; and the lowest cold 14°, on the 3rd, 1862. The greatest fall of rain was 0.48 inch.

BROMELIACEOUS PLANTS.—No. 2.

BROMELIA LONGIFOLIA.—Bromelia is the genus which gives the name to the whole order, and it contains several species of great beauty. That now under consideration well deserves a place in every plant stove, or it may be planted in the fernery, where, placed in a suitable position, it forms no mean object, and as its bracts are hard and persistent, the moist atmosphere which it is necessary to maintain does not affect them. The leaves of B. longifolia are usually from 18 to 24 inches in length, somewhat narrow, and armed with long spines;

Bromelia longifolia.

the upper surface is dull green, while beneath they are silvery white. The head of flowers proceeding from the centre of the plant is very dense and bright rose colour, whilst the bracts which accompany them are deep crimson. It usually comes into bloom about the end of July, and retains its full beauty for a long time. Its native country is Guiana; it was introduced to our gardens about 1846.

B. Fernandæ.—This is a plant of quite recent introduction, having been discovered in 1866 by that indefatigable traveller and collector Mr. G. Wallis. It is a native of Para, affecting the forests bordering upon the river Amazon. It flowered for the first time in Europe in 1870, and is beautifully figured in the June number of "L'Illustration Horticole," published under the direction of the distinguished Belgian nurseryman, M. J. Linden, thus affording another proof of my former remark, that the public taste for these plants is decidedly upon the increase. This species is a robust grower, producing long, somewhat narrow, acuminate leaves, which are channelled above and rather distantly toothed with short obtuse spines; they are full dark green on the upper side, tinged below with dull red. The whole plant presents a somewhat vase-like appearance, its long leaves arching, and the upper portion becoming pendulous. The flowers are produced in a large capitate head, and they, or rather the surroundings bracts, have a grand effect; these bracts are very numerous, brilliant carmine red on the upper side, somewhat paler below. This is, undoubtedly, a magnificent plant, and I hope to see it widely distributed when M. J. Linden places it in commerce.

Distiacanthus scarlatinus.—I have no knowledge of this genus, and cannot say in what it differs. This plant was first exhibited in Brussels, I believe in 1867 or 1868—I am not quite sure which—and attracted much attention at that time. Since then I have occasionally seen it, and although it is certainly not amongst the most superb of its class, it is well deserving the attention of all plant-growers who are not limited for room. The plant is of robust growth; the leaves are long and spreading; the flowers do not rise above the foliage, and the chief attraction is the vivid scarlet of the inner leaves, which retain their intensity of colour for a long time. It is a native of the country bordering upon the river Amazon, and enjoys an abundance of heat and moisture.

Bilbergia.

A genus distinguished for numerous beautiful species, many of which exist in our gardens. They may be grown in great perfection on blocks of wood, or in baskets suspended from the roof of the stove; in this way they are frequently grown in verandahs by the inhabitants of Brazil and other parts of South America, their brilliant colours and lasting beauty making them general favourites, even where gay flowers are not rare. However, if it should better suit the taste or convenience of the amateur to have them in pots, there is nothing to prevent this method of cultivation being adopted. The pots must be well drained, and the soil should be two parts fibrous peat to one part of loam, and my previous remarks concerning watering these plants must be followed out if good plants and flowers are looked for.

B. Baraquiniana is a native of the Amazon country, and delights in strong heat. The leaves are somewhat narrow, some 18 inches high, and erect. Like the leaves of all this family, they overlap at the base; they are pendulous at the ends, and in colour bright green, with several transverse bands of powdery white underneath, being, in addition, armed at the edges with red spines. The spikes of flower are pendulous at the upper part, and the stem densely powdered with white. The flowers are green, and the stamens much exserted; these colours, however, are beautifully set-off by the large oblong bracts, which are of a brilliant scarlet. When grown in a basket, and

well established, its numerous gay spikes render it a very attractive object, and as these usually appear early in spring it is all the more valuable.

B. THYRSOIDEA.—This is a magnificent Brazilian species, erect in habit, with numerous broad, clear, bright green leaves, armed at the edges with numerous sharp spines. It is of robust habit, and I prefer to grow it in a pot with rather more loam than usual. The gay inflorescence is erect, both flowers and bract being of an intense rich crimson.

B. MINIATA-ROSEA is another species from the same country as the last-named. I prefer growing it upon a block or in a small basket. The leaves are semi-erect, spreading outwards, and recurved towards the apex, armed at the edges, and light green, overspread with a thin farinose covering. The scape is erect, producing quite a number of flowers of a deep rose colour; the bracts are large, deep red tipped with blue, and suffused with a white farinose powder, which gives it a peculiarly handsome appearance as if clothed with hoar frost.

B. MARMORATA.—This is a very strong-growing kind, which should be grown in a pot or planted in an erect position in a pocket in a rockery; indeed, many species of this order make charming objects in a similar situation. The leaves are broad, regularly armed at the edges with spines, deep green, mottled and blotched with dull red. The scape is erect; the flowers dark blue; the calyx green at the base, but tipped with the same deep blue as the flowers; the bracts large, and, like the stems, of a uniform brilliant scarlet. It is a native of various parts of Brazil.

B. MORELIANA.—Another fine plant from Brazil and South America. The leaves are broad, dark green, banded on the under side with a white farinose powder. The bracts and flowers are extremely handsome; the flowers are deep violet, beautifully set-off by the large persistent rich reddish rose-coloured bracts, which are its chief attraction.—EXPERTO CREDE.

POTATO CULTURE.

THE Potato-planting season is at hand. It is, perhaps, not easy to say anything that is not generally known respecting this the most useful of all root crops. Change of seed is no doubt good, but change of soil is better. At first sight it would appear that one change involves the other; so in one sense it does, but there is a difference. If seed is procured from a brown hazel loamy soil, and planted in a garden of rich black vegetable mould, a benefit is derived by the mere change of seed; but if seed is saved from that black vegetable soil and planted again in the same garden, but in a plot containing a large admixture of fresh field soil, the benefit is still greater, and change of soil is, therefore, better than change of seed. As an instance, I may state that the soil I have to operate on is the dark vegetable mould of a very old garden. For the past six years seed of the same kind has been grown and again planted in the same garden, and each year the crops have been better than in the past. This is a direct result of change of soil. The soil introduced was roadside trimmings and parings, or failing this, a load or two of the garden soil was exchanged for field soil. The practice is mutually beneficial, and as manure is saved, is economical also. It is surprising how soon the staple of an old garden may be improved by steadily carrying out a simple system of exchange of soil. Nothing more fully proves the truth of the old maxim that "exchange is no robbery" than a practice of this kind. The vegetable soil of the garden improves the field, and the field soil the garden. Every year, also, I have had seed grown in the field and planted in the garden, but in no one instance has the produce been so good as from seed grown in the garden and planted in the garden with a good admixture of fresh soil. Fresh soil in an old garden is infinitely better than manure for Potatoes, and, with a limited quantity of manure, for all other crops too. The practice cannot be carried out in all places, but it can in many. Likewise, it cannot be carried out to influence the entire crop of Potatoes. In this event change of seed must be resorted to. There is room for a few words on this subject.

It is a popular notion that seed should be procured from a light sandy soil. That impression is held so strongly and authoritatively that in some districts it amounts to an absolute rule. Now, in general, I do not believe in rules relative to soil, management, and general culture, and at the risk of appearing singular I put aside the notion or rule above stated, lay down another diametrically opposite—that Potatoes for seed should be drawn from a stiff soil, and assert that it is as safe and sound as the old light-soil theory. An inflexible adherence to either theory, however, is not wise. The soil to which the Potatoes have come should be considered as well as the soil whence they come, to rightly determine a change.

On the matter of change of seed I claim a lengthened experience, which added to some years of observation and practice leads me to the conclusion that as a whole, and speaking generally, seed grown in a strong soil will afford a better yield than those grown in light sandy soil.

My father was regarded in his little sphere as a "great Potato man." Potatoes were a vital question with him, having to bring up a family of eight on from 10*s.* to 15*s.* per week. He had Potatoes in isolated plots, in all sorts of soils. Such a position made a man look out and endeavour to turn an honest penny by any possible means. His experience of fifty years taught him that the plan that paid him the best was to obtain seed from strong soils. I will add to that fifty years twenty more of my own individual observation and practice, and I arrive at the same conclusion. I have tried to prove it and disprove it fairly, over and over again; the last time was in the past year. I planted a rood of medium soil, fine Potato land, using one kind of Potatoes, with equal portions of seed from light sandy land, strong warp land, and fen land. The warp seed gave the best yield, fen next; that from the sandy land coming out a bad third. If I had a thousand acres of such land to plant I would, if possible, draw all my seed from warp land, and none from soil of a light sandy nature. My experience is, that the poorer and more sandy the soil, the more and the smaller the eyes in the tubers; the stronger and heavier the soil, the fewer and finer are the eyes formed. Now, a fine stout stem will produce a fine root of Potatoes. A cluster of wiry-looking stems produces a multitude of small trashy tubers. Two or three eyes, whether on a cut Potato or a whole one, will give a better yield than half a dozen smaller shoots springing from the same set. If, then, a whole Potato is planted, it is wise to take out a number of eyes before putting it in the ground. A rough and expeditious mode is to cut off, by a slice, the cluster of eyes at the end of the tuber; a slower but better plan is to pick out all but two or three of the most prominent. Cut Potatoes are as good as whole ones if not less than two good eyes are secured to each set; but the sets are better if the whole tubers are not disbudded for the reason above stated.

It is unwise to put freshly cut Potatoes in sacks or in large heaps and leave them there for a length of time, as they will often heat. This kills the eyes and is the cause of many blanks one meets with, and which cause some surprise. If allowed to dry, and the wound to heal over before being packed away for a reasonable time, no harm will result. Dusting newly cut seed with lime hastens the wound healing and is good practice. It is a bad plan to allow seed Potatoes to lie thickly and produce long weak sprouts which must be rubbed off. Allowing them to be produced weakens the Potato and tends to cause disease. This neglectful plan, by impairing the vital force of the tubers year by year, has done more to foster disease than almost anything else. Bleed the lambs and calves a few times in their infancy, and continue the practice for a few years, and what sort of flocks and herds would be the result?

As regards planting, in light and dry soils plant early and deep; in cold, wet, and heavy soils, late and shallow. By planting Ashleafs, for instance, in light soil in this dry district, 5 or 6 inches deep in February, I obtain quite double the crop as compared with late and shallow planting. The roots take a good hold of the soil, and are out of reach of the sun's rays, which otherwise burn them up extensively. On the other hand, in wet strong soils the second week of April is quite early enough for planting the same kinds. In such soils planting on the surface, and digging trenches between the rows to cover the sets, cannot be too strongly recommended. I have seen fine crops on this plan on ground worthless for Potatoes if planted in any other way. For free workable soils the ridge-and-trench plan has no advantages, at least I have seen none, over the ordinary level system of planting.—J. WRIGHT, *Gardener to Hon. A. L. Melville.*

SPRING-BLOOMING PLANTS IN THE DUBLIN BOTANIC GARDEN.

AMONG the pleasures which a traveller has may be reckoned the opportunities he has of visiting botanic gardens. I have this afternoon (February 24th) spent several pleasant hours in those at Glasnevin, Dublin. These have, I consider, the

most beautiful grounds of any botanic gardens in the United Kingdom. My object in writing to you is to bring before your subscribers information which in years gone by would have been very useful to myself; for, being an ardent lover of flowers and fond of cultivating them, I was exceedingly desirous of having early-blooming plants in my garden, and succeeded in that respect in far surpassing all my neighbours in a wealthy neighbourhood; but the spring-blooming plants I then knew were few in comparison with those I have this day (Feb. 24th) seen in blossom.—P. N. W.

MUSHROOM CULTURE.

Have the dung in good order, neither too dry nor too wet, and keep it about a hundred days to allow of its getting cold. In making the bed beat it thrice, the harder the better, and I always have the dung beaten very small before heating, as then the heat is more lasting than would otherwise be the case. With the last lot of dung to go on the bed I always mix loam, as then the spawn runs better. When the bed is made I insert a drain-pipe in the middle, put a thermometer in it to show the exact heat, and when the temperature is 70° or 80° I place the spawn on the top of the bed, cover it with 2 inches of hot dung and loam, and beat down hard. Some people cover the bed with straw or hay; I do not, as I find it answers much better without anything. Keep the air of the house at 65° or 70° and moist, and in six or seven weeks there will be Mushrooms fit for use. If the bed becomes too dry, supply water of the same heat as the bed.

In taking the crop cut as you like. I cut mine with about an inch of stem. Three days after cutting look at the old stems, and you will find them moulding at the soil; if they are allowed to remain they will spoil many good Mushrooms; take them between the forefinger and thumb, give them a twist, and they will come off easily without spoiling the others. By this management I have as good a bed as one could see. Do not allow even a drop of rain to reach the dung.—J. W. Crowood.

[There are good ideas in your communication, but on the whole "much cry and little wool." First, with regard to having Mushroom dung in preparation for a hundred days. Why, with the roughest material we would often have a heavy first crop and a second bed coming on in that time. Secondly, with respect to the beating of the dung so small before heating, we convinced ourselves more than thirty years ago that it is worse than a mere waste of labour. We would rather keep the good properties of the dung. Thirdly, as regards not putting any covering on the bed, it is a matter to be regulated by circumstances. In a regularly heated house it is not required. In the open air or in open sheds the covering is indispensable, perhaps not so much with the view of securing a crop as for getting the crop when you want it. It is a poor result to obtain Mushrooms in six months when you want them in six weeks. Before spawning the thermometer is useful, but any gardener will know the heat by a mere trial-stick inserted in the bed. The mode of gathering will always be a disputed matter. Some twist and some cut, and where there was a good bed we could never discern any difference in the result. It is better not to use too large pieces of spawn, nor to place them thickly together, and then the Mushrooms do not come up in such large masses as to render the gathering difficult. Ever since we received lessons of economy from a man cook we have been careful to send Mushrooms with almost every bit of stalk. He showed us a dozen large preserving-bottles filled with little bits of the stems of Mushrooms, and these for most purposes were just as useful as small button Mushrooms.—R. F.]

LYCOPODS.

When a regular supply of plants is required for room-decoration, Lycopods are indispensable. They possess charms peculiarly their own, and their pleasing shades of green enhance the beauty of all plants with which they are associated. The gardener who has a well-grown collection to choose from for the purpose indicated, has at his command an acquisition that cannot fail to be of service to him, and impart pleasure to those whom it is his duty to please.

The culture of the majority of Lycopods is simple, and might be summed-up as follows: A regular supply of moisture, shade from the direct rays of the sun, a still atmosphere, and good drainage. This is applicable to both greenhouse and stove species; neither will succeed well if exposed to scorching sunshine, a dry airy atmosphere, want of water, or bad drainage. The size that Lycopods can be grown to is limited only by the room at the disposal of the cultivator. Large pans of Lycopods are very beautiful, and for special purposes it is desirable to have a few such; but for general usefulness small plants are preferable. Their most important use is edgings to vases and baskets, and as carpeting to other plants used in the decoration of rooms; and for both purposes small plants are superior to large masses. It is best, therefore, to grow a number of the more useful varieties in small pots, say from 2 to 8 inches in diameter. The former will be found very useful, and the latter is large enough for most purposes. Those growers who have only a greenhouse will find April a good month to repot them. Where there is a vinery repotting can be done in March, as in most cases the Vines will then be receiving assistance from fire heat; and the additional temperature and moisture of the vinery will assist the Lycopods to establish themselves with greater certainty of future well-doing. In repotting, use clean pots, both inside and out, and be careful to drain them properly, remembering that the plants will require daily supplies of water; and if the drainage is imperfect, the soil will soon get sour, and the plants cease to thrive. A few days previous to repotting, have the fresh soil taken into the structure where the plants are growing, so that it may get warmed, and be in fit condition to receive them.

All the greenhouse Lycopods will grow well in a mixture of fibry loam and leaf mould, with sufficient silver sand and pounded potsherds added to keep it porous. Let the loam be rather rough—the plants will do all the better for it being so. When ready to commence repotting, turn the plants out of their pots, and divide them into the requisite number of pieces, taking care in the case of the branching varieties, such as Selaginella stolonifera, to secure a piece of root with each division. Fill the pots with the compost described, and press it rather firm, keeping it a little higher in the centre of the pot; then with a stick for the purpose make a hole in the centre, and insert a division of Lycopod, around which, towards the edge of the pot, insert as many pieces as may be thought necessary to form a symmetrical plant. When potted, place the plants in the least airy part of whatever structure they are to stand in, but in such a position as they will not be exposed to hot air from the hot-water pipes or flues. Give them a good watering through a fine rose, attend to the directions already given, and in due time you will be rewarded for your care.

For the benefit of those who may not be acquainted with Lycopods, I append the names of twelve that can be successfully grown in a greenhouse. Selaginella apoda, Moss-like habit, very beautiful; S. Martensii, close habit; S. flexuosa, small branching fronds, pretty; formosa, very close habit, a most useful variety; S. Wildenovi, handsome drooping Fern-like fronds; S. cordifolia, grows about 6 inches high, very elegant; S. Schotti; S. denticulata, will grow almost any-

where, and for general usefulness and carpeting to other plants it has no rival; S. stolonifera, an easy-grown useful sort; S. Burghalli; S. cæsia; S. cuspidata, very pretty, forms a bird's nest, fronds branched.—(*The Gardener.*)

BLACK HAMBURGH OR BLACK HAMBRA GRAPE.

"What's in a name?" Not much, perhaps, unless it leads to correct apprehension; and the name "Black Hamburgh Grape" does lead to the erroneous idea that the original Grape was brought to England from the German port of Hamburg, sometimes spelt Hambro', a place where the Vine does not grow except under hothouse culture.

The Vine in question was introduced into England, I believe, by Mr. Warner about 150 years ago, the original Vine being found by him at the Moorish Palace in Spain called the Palace of Al Hambra, whence he called it the Black Hambra Grape. Now, the Palace in question being little known in comparison with the town of Hamburg, the spelling was soon by many persons corrupted to Black Hambro', the final letter only being changed. When that spelling became general it, no doubt, somewhat obscured the history of the Grape; but the present spelling, Black Hamburgh, does so effectually, and it seems to me, therefore, desirable that the original spelling, Black Hambra Grape, should be at once restored.—T. Thompson, *Welton, Brough, Yorkshire.*

[The derivation you advocate deserves to be correct. This Grape and the Red Hambro' were introduced in 1724 by Mr. Warner, and cultivated by him in his garden at Rotherhithe. It is described in many books as *Warner's Grape.* Bradley mentions him as "a gentleman who makes good wine from his own vineyards." The opinion that both the varieties were brought from Spain is in some degree sustained by the fact that the Red Hamburgh is spoken of by some writers as the Gibraltar Grape. Such names, however, are not reliable evidence of derivation, for the Turkey is certainly not a native of that empire. We know of no positive record that Mr. Warner obtained the varieties from Spain; and if he obtained them by the agency of Hamburg merchants that town's name might naturally have been applied.—Eds.]

LOVE OF EXCESSIVE PRUNING, EVEN THE STRAWBERRY PLANT.

Pruning is by many considered an absolute necessity. By others, including myself, it is believed to be of little importance; and certainly there are the laws of Nature to support the latter conclusion. This is pre-eminently an age of pruning. What escapes the knife or shears? Nothing, not even the Strawberry plant. I think there are many crops endangered, nay, wholly destroyed, as lately stated in these columns, by strictly adhering to a fashion of pruning. How few of the many amateurs' gardens do not bear ghastly marks of the same! Enter one on a fine day, and nip! nip! nip! will be the sound that will greet you long before any person is visible. Yes, here it is. Walks strewed with the tops of every possible shrub; all are subjected to that love of using the knife, or more commonly scissors. Fruit, flowers, and foliage are all cut for the twentieth time the same summer. Of course, any part of the shrub that is out of arm's reach is left in all its wild profusion. What a contrast to that which is under the hand with a pair of nippers! It seems almost incredible, but such is a fact. One instance will suffice. I knew a retired steward, a person we should suppose would have known better. Whenever he was in the garden, a stout pair of pruning scissors were his companions: woe to any shrub that had made a growth of a few inches. A fine lot of Rhododendrons had bloomed well the first season after planting. It was the first and last, for as soon as the annual growth began the nippers had their usual work to do. The same thing is too often seen in a less marked degree with professional gardeners. How can it be said

> "This is an art which does mend Nature,
> Change it rather, but
> The art itself is Nature."

But to Strawberries again. I am always open to conviction, but I have not yet, after many years' practice, found it necessary to pinch off all the runners. Doing so causes an undue exertion of the parent plant to put forth new ones, and so a constant strain is kept on it in that direction; whereas, if left, the offspring will soon take root and maintain itself, and then, like a dutiful parent, after her young are established, she takes care of herself and makes no further exertion for a new brood. Deprive her of them, and she instantly begins again. I believe there is little or no strain on the parent when the young plant takes root; sever it when slightly rooted, and it will maintain itself. The extra labour required in going over the plants five or six times I say nothing about. "They want plenty of muck under them if you keep pinching off the runners" said a brother gardener when I was speaking to him on this subject. I do not vindicate the practice of leaving ground a mass of Strawberries for months, for this would be impoverishing the ground, which would be equal to impoverishing the parent plant by continually nipping off the runners. Does it not endanger the plant, too, to keep up this activity too late in the autumn, so that before growth is thoroughly matured, winter is on it, and leaves its marks by destroying the major part of them, especially those of a tender constitution?

There is yet another practice; happily I believe it is not carried on to any great extent, nor yet so much as formerly. If we were to reflect for one moment, and consider the importance of the leaf, surely no one would venture to take a scythe and cut off the leaves long before they assume the appearance of having performed the functions allotted to them. Many years ago my father was persuaded to do it, under the idea, as his informant assured him, of doubling his crop the following year. Forthwith, upwards of an acre of beautiful luxuriant foliage was destroyed. But was the crop doubled next summer? No, nor was there half the crop usually obtained; and as market gardening is a matter of pounds, shillings, and pence, it was the first and last time the leaves of Strawberries were molested by him. Leave them; they help to protect the plant through the winter.—J. T., *Maesgwynne, South Wales.*

ENTOMOLOGICAL SOCIETY'S MEETING.

The annual meeting for the election of Council and officers, and other routine business, was held on the 22nd of January at Burlington House, the President, A. R. Wallace, Esq., being in the chair, by whom an address was delivered on the progress of the science, dwelling especially on the views recently advanced as to the gradual evolution of insect life by tracing it back to some primary germ or element, views subversive of intelligent design and creation in the animal world. The following gentlemen were elected as officers for the ensuing year:—President, Professor Westwood; Treasurer, Mr. S. Stevens; Secretaries, Messrs. Grut and McLachlan; and Curator, Mr. Ianson.

The first ordinary meeting in February was held on the 5th inst., the newly-elected President in the chair, who returned thanks for his election, and expressed a hope that his efforts for making the meetings of the Society successful would be seconded by the members keeping the benefit of the science and of the Society in view rather than indulging in personal discussions; the President then nominated Messrs. F. Smith, H. T. Stainton, and Edward Saunders to act as Vice-Presidents. A large and important list of accessions to the Society's library was announced, and certificates read in favour of five new members. Mr. F. Smith read a note from Mr. Moggridge, at Mentone, relative to the publication of his notes on the habits of Ants. Mr. McLachlan exhibited part of a branch of a Poplar tree growing at Kentish Town covered with the desiccated skins of Aphides, which had been destroyed by some parasite, resembling clusters of the eggs of some large species of insect.

Major Parry read a paper containing descriptions of a number of new and very fine exotic Stag Beetles, including a very remarkable species just brought from Ecuador by Mr. Buckley. Mr. Bates, in reference to this insect and the geographical range of the family, stated that during the whole of his residence on the banks of the river Amazon, for eleven years, he had never once captured a Lucanus. Mr. Druce exhibited a number of cases containing portions of a very extensive series of Butterflies recently received from Costa Rica, collected by M. Van Patten, amongst which were at least fifty species new to science; three of these belonged to the genus Papilio, three to Morpho, three or four to Leptalis, and a new genus allied to Pronophila. Some of these new species had been already described by Mr. Butler in the "Cistula Entomologica."

Professor Westwood exhibited several new Arachnida belonging to families and species not previously recorded as British, including a species of the genus Trogulus, taken by Rev. P. Cambridge in Dorsetshire; the singular Argas reflexus, of which a colony had been found under a stone in the crypt of Canterbury Cathedral; a new species of the same genus taken in the church of Whittlesford, Cambridgeshire, apparently parasitic on the Noctule bat; also a specimen of the poisonous Argas persicus from Persia; and a new genus from Sumatra, allied to

the cavern-dwelling genus Hyphophthalmus. Mr. F. Smith stated that a specimen of the Dog Tick had been sent him from Canterbury Cathedral as a fat Spider peculiar to that building.

Mr. Lewis made some observations on the nomenclature of Lepidopterous insects, occasioned by Mr. Crotch's paper in the last part of the "Cistula Entomologica."

EFFECTS OF BOTTOM HEAT ON PLANTS GROWING OUT OF DOORS.

The following facts are of sufficient practical importance, I think, to merit attention, and some of your readers may probably have something further to say on this subject.

Late in the spring of 1870, we had occasion to move a number of somewhat stunted common Laurels that formed part of a bank. Some of them were planted about the pleasure grounds in ordinarily favourable situations, but as the season was very dry they may be said to have survived only without making any growth. Last year (1871) they recovered themselves, and made about 6 inches of young wood generally. I state these facts for the purpose of comparison. Another lot of the same plants were planted behind a lean-to Melon pit, on a north aspect to hide the brick wall, and, so far as soil and situation are concerned, under less favourable circumstances than the others. Instead of remaining dormant the first year, however, they started into growth immediately, and by midsummer had made a luxuriant growth, when they rested a bit and then made a fresh start again, finishing a still more luxuriant growth about the end of October, and producing two distinct growths on every shoot, each about 1 foot in length, and which anyone unacquainted with the circumstances would have pronounced decidedly to be two years' growth; the first growth having all the hardness and matrurity of a last year's shoot. As the later growths were soft, and as last winter was severe, I fully expected they would be killed by the frost; but they suffered no injury whatever, while the Laurels in other places were browned considerably.

Last summer (1871) they again made two distinct growths, adding to their stature from 3 to 5 feet in two years. Now for the secret. The pit against which the Laurels are growing is kept at a high temperature all the year round, and the ground where the roots of the shrubs are is about a foot or more above the level of the path inside the Melon house, hence the warmth to the ground outside for nearly 4 feet from the wall.

I tested the temperature of the soil among the roots of the Laurels, about 2 feet from the wall, and found it to be 46°; while in an open bed, a few paces off, the thermometer stood at 39°; this was about the end of December last.

I think it is Dr. Lindley who somewhere discusses the probability of plants having the power to resist a considerable degree of cold when their roots are in a comparatively warm medium, the theory being that the heat is communicated to the stems and leaves through the roots. The facts I have stated would seem to bear out such a theory; and, no doubt, similar instances might be recorded. Some of your readers will perhaps remember a paragraph which appeared in a contemporary some time ago, recording ripe Strawberries in the open air early in May, if I recollect aright, in Yorkshire. This was true enough, but their earliness was due to a strong bottom heat, originating from nothing less than a coal pit on fire. We saw the Strawberry patch in question last summer, and found the plants blooming and bearing then, in a bottom heat of 85° or 90°.

With such facts as these before us, we may reasonably suppose that such things as Apples and Pears, &c., might be safely and advantageously treated to a higher root temperature, when growing out of doors, than is naturally communicated to the soil under ordinary conditions. There can be little doubt that, with their roots in a comparatively warm temperature, the trees would be able to resist a greater degree of cold when in bloom, and we may be sure the fruit would be earlier and better ripened. Here, on the extreme limits of Pear-growing, we have been cogitating on the practicability of heated borders for the better kinds of dessert Apples and Pears. We would propose to plant in quantity dwarf pyramids in rows about 6 feet apart and would furnish bottom heat by means of 2-inch hot-water pipes; a single row of pipes being laid under each row of trees, burying them in the subsoil, say 4 feet from the surface. This would be ample heating power, and the depth at which the pipes lay would prevent all danger from accidents to the roots. Mulching the surface would, of course, be advantageous in various ways, and be a means of economising the heat. I am not aware that anything of this kind has been tried yet; and these are only suggestions, which I leave your readers to discuss.—J. S., *Wortley*.

[Along with this we have received a shoot of Laurel from Mr. Simpson, showing the two distinct growths, each about 1 foot in length.]—(*The Gardener.*)

Rose in Flower.—To show the mildness of the present season, let me mention that I have a Lamarque (Noisette) Rose tree in bloom in the open air (Feb. 26th). Will any of your subscribers say if they have ever known a Noisette Rose tree bloom in February? The tree is against a south wall, and was only planted last spring.—John R. M. Camm, *Monkton Wyld, Charmouth.*

INFLUENCE OF MANURES—PREPARING GROUND FOR ROSES.

In my former communication I was induced to make a few remarks as to the possibility of iron and other agents having a marked effect on the growth of plants; and, I may mention that I was much interested by the account contained in your columns of some experiments with regard to the influence of this and other manures on the colours of plants. By these, it appears that iron does not produce so marked an effect on the growth as might have been expected. I myself think that iron, being a constituent in the blood of animals, must be a necessary one in the ash of plants.

Two or three other manures occur to my mind, the effect of which can only be mechanical. Of these cocoa-nut fibre and charcoal are notable instances. The former may be very valuable in its way for Orchids, or any plant requiring a fibrous soil; and I have no doubt that your correspondent's suggestion that Hyacinths may be very successfully grown in it is a good one; but the actual manurial value of either may be considered almost *nil*.

I should now like to give my ideas as to the best method of forming a rosarium; and although the subject is one that has been often pretty well handled, I may, perhaps, notwithstanding, be able to throw a little fresh light upon it.

The first thing to be seen to is that the soil is brought into a proper state by mechanical means, and the second that it is enriched to such a degree as to insure success. If your soil is light, and you intend to grow the Briar to some extent, or even Roses on their own roots, you must stiffen it more or less. Where money is no object, you may get a contractor to provide you at, perhaps, a cost of 10*s.* to 15*s.* per load, with some rich clay loam and grass sods to a depth of two spits; but if you cannot afford this, take the opportunity of laying-in a stock of good clay, which you may often obtain for little more than the cost of cartage. This should be put on to the extent of 4 inches in depth, or about a barrowload to a square yard, and left exposed to the action of the winter's frosts until the spring, when the process of amalgamation will be found to be much accelerated. Your plants, if already purchased, should in the meanwhile be carefully laid-in in a sheltered spot. If you happen to have one of those wretched gravelly soils mentioned by the Rev. S. R. Hole, add a quantity equal to its own bulk of the best ordinary soil that can be procured; and where burning it is practicable, I strongly recommend clay. If your soil is rather stiff it must be somewhat lightened for the Manetti and China Roses, and this can be effected by addition of sand or light loam.

I now come to the important question of manure. I strongly inculcate laying a good foundation of what is best called mineral manure. For obtaining a supply of phosphoric acid I recommend bones; and I do not think it is of great moment in a proper close soil whether they are half-inch or crushed, though perhaps the latter may be rather slower and more lasting. Apply them at the rate of two tons per acre, or 1 lb. per square yard, and even double this amount may be given with safety, as this only allows about 3 ounces for the 12 inches deep of soil, the least we can calculate to enrich. One per cent. would be a grand basis. Potash must next be supplied, if it is even at the risk of some trouble or of disgusting your gardener. It should be sulphate of potash, and should be applied to the extent of half the quantity of bone dust. Be careful, however, not to buy any substance containing only a

small per-centage of potash, as the application must then be considerably increased, and is consequently rather more dangerous; it must therefore be used with caution, especially in the case of pot Roses.

Thus enriched there is no absolute necessity to use farmyard manure, but a littering-over after planting, or the following autumn, may be useful for protecting the roots. For prize Roses we must apply some nitrogen every spring by watering with the liquid drainings of dung heaps, or dissolved guano, or nitrate of soda, to act as the so-called stimulant, producing a strong and rapid growth, and rendering the other food more soluble. Be careful to dilute well, and choose wet days for application.

If with soil thus treated in a favourable situation and with proper drainage, &c., you cannot vie with your neighbours in growing good Roses, then I will cease to offer any advice on the subject, and listen with patience to the praise of fibre shavings and scrapings or sawdust, and acknowledge that there is something very peculiar and incomprehensible about the predilections of this plant. I am glad to see that Mr. Radclyffe does not express great faith in the iron manure. I should like to ask him whether a climbing Rose in a very dry position would have its roots kept damper or otherwise by placing a slab of stone over it. I should also like to know where I can get a well-grown plant of Cloth of Gold Rose for a greenhouse wall.—J. S. K.

P.S.—I have just noted the Rev. C. P. Peach's communication. He has to some extent misunderstood me, as a perusal of the foregoing will show; but I will proffer a few remarks on his views in your next issue.

GRAFTING.—No. 3.

The examples we have given of inarching in our previous papers are those which are most generally adopted among us; but there are numerous other forms of it practised by the French in constructing the fancifully-shaped fruit trees met with in the gardens of the *bourgeoisie* in the suburbs of the large towns of France, which we consider of little use to our readers. One example of this style is shown in *fig.* 1, where

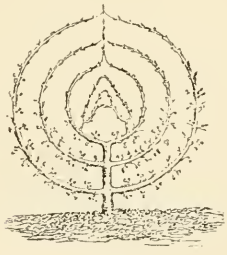

Fig. 1.

the branches, following a regular curve representing a target, meet at the summit and are united by grafting. In the centre M. Forest, who is skilful in this sort of training, has formed a letter A by means of inarching. In the garden of M. Nallet, of Brunoy, his name NALLET is reproduced in six trees. In the same way M. Baltet has formed his own name by the junction of trees by means of inarching.

There are several other illustrations of this mode of training and inarching given in M. Baltet's book, but those which are really of useful application are those that are thus described.

We have ascertained the good effect of inarching the principal branches of winged pyramids, goblets, and lyre-shaped trees, either isolated or in trelliswork, in the fruit garden of M. A. Mas, pomologist at Bourg, and in the orchard of the École d'Agriculture at Soulaise (Ain) formed by Verrier. The *single cordon*, particularly applicable to the Apple tree, ought to be terminated by grafting it into another, each leader being pruned at the extremity in a slanting cut, and introduced under the bark of its neighbour at the curved part by the system of buttress-inarching (*fig* 2); a continuous line of small trees well balanced is thus obtained.

Fig. 2.

[M. Baltet then proceeds to give an example of grafting which cannot be called inarching, since the scion is free and does not remain in contact with its parent. It is employed to fill up a space between single cordons when the leader is not long enough to reach from one to the other, and it is done by grafting a scion of the length required, first the base into the summit of the leader, and the apex into the curve of the neighbouring cordon. The next illustration is ingenious if not productive of great results.]

Inarching Applied to Increase the Size of Fruit.—This application of inarching is not very widely practised, because on the one hand it requires some skill on the part of the operator, and on the other success does not always reward the work. We have meanwhile authenticated more than once its good results, and particularly with M. Luizet, fruit-grower at Eculty. He exhibited beautiful specimens of it at Lyons in 1856 at the institution of the Congrès pomologique.

About the month of June a young herbaceous shoot is inarched on the stalk of a Pear (*fig.* 3). It is bound with a

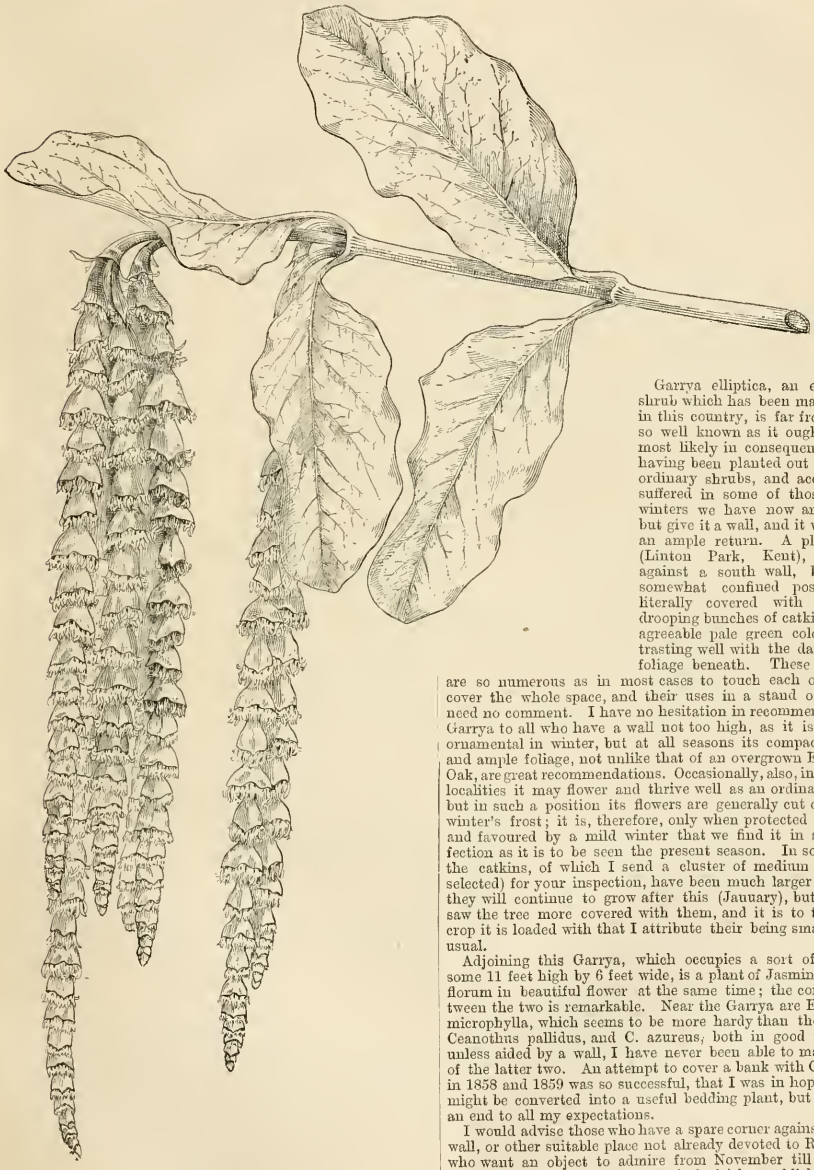
Fig. 3.

woollen ligature without bringing the two parts too closely in contact. If the shoot continues to grow vigorously the extremity ought to be pinched, but if it sets at the extremity then it is to be left alone. It is thought that the fruit, receiving by this means a supply of nutrition, ought thus to increase in size. When the fruit is produced on a fruit-bearing spray, a nurse-scion can be grafted on the spray besides the scion grafted on the stalk of the fruit. We have tried it successfully. In the case of fruit with too short or too fine a stalk, as the Apple and the Peach, the herbaceous shoot on the fruit-bearing branch is to be grafted by the ordinary mode of inarching or buttress fashion, as near as possible to the point of junction of the fruit on the branch. The ligatures of grafts will be in these two examples tied in such a way that they can be loosened without cutting should they become too tight.—Charles Baltet, *L'Art de Greffer*.

GARRYA ELLIPTICA.

Gardens would be dreary in winter were it not for evergreens, and in those districts where the severity of the climate limits the number of such ornaments, the few that can withstand it are the more prized. It is fortunate that among these there happen to be two or three of the most handsome evergreens we have. Hollies, Rhododendrons, Box, and Juniper are all very hardy and beautiful as well. The Holly, in par-

ticular, is invaluable from its clothing our woods and dressed grounds in the loveliest of green, enlivened, too, during the winter by multitudes of carmine berries. My purpose, however, is not to call attention to the Holly and the other hardy plants referred to, but to urge the claims to greater attention of a shrub which is not so hardy as they are.



Garrya elliptica.

Garrya elliptica, an evergreen shrub which has been many years in this country, is far from being so well known as it ought to be, most likely in consequence of its having been planted out amongst ordinary shrubs, and accordingly suffered in some of those severe winters we have now and then; but give it a wall, and it will make an ample return. A plant here (Linton Park, Kent), growing against a south wall, but in a somewhat confined position, is literally covered with its long drooping bunches of catkins of an agreeable pale green colour, contrasting well with the dark green foliage beneath. These bunches are so numerous as in most cases to touch each other and cover the whole space, and their uses in a stand of flowers need no comment. I have no hesitation in recommending the Garrya to all who have a wall not too high, as it is not only ornamental in winter, but at all seasons its compact growth and ample foliage, not unlike that of an overgrown Evergreen Oak, are great recommendations. Occasionally, also, in favoured localities it may flower and thrive well as an ordinary shrub, but in such a position its flowers are generally cut off by the winter's frost; it is, therefore, only when protected by a wall and favoured by a mild winter that we find it in such perfection as it is to be seen the present season. In some years the catkins, of which I send a cluster of medium size (not selected) for your inspection, have been much larger; indeed, they will continue to grow after this (January), but I never saw the tree more covered with them, and it is to the heavy crop it is loaded with that I attribute their being smaller than usual.

Adjoining this Garrya, which occupies a sort of buttress some 11 feet high by 6 feet wide, is a plant of Jasminum nudiflorum in beautiful flower at the same time; the contrast between the two is remarkable. Near the Garrya are Edwardsia microphylla, which seems to be more hardy than the Garrya, Ceanothus pallidus, and C. azureus, both in good form, but unless aided by a wall, I have never been able to make much of the latter two. An attempt to cover a bank with C. azureus in 1858 and 1859 was so successful, that I was in hopes that it might be converted into a useful bedding plant, but 1860 put an end to all my expectations.

I would advise those who have a spare corner against a south wall, or other suitable place not already devoted to Roses, and who want an object to admire from November till April, to plant Garrya elliptica, and after it is fairly established not to

prune nor trim it too much. Tie it in a little if it project too far, but in the summer dressing leave a number of the shoots at their full length, otherwise, in all probability, there will be no blossom, as it is all at the points, or what botanists call terminal.—J. Robson.

A SOJOURN IN THE HIGHLANDS OF SCOTLAND.

(*Continued from page* 127.)

The morning of the eighth day was again gloriously fine and we determined to devote it to the valley of the Lochart. This valley or glen is rather narrow, and the sides of the mountains are not so well wooded as those of the Lochay. Our main object was to hunt for varieties of Blechnum and Lastrea montana, of both which there was plenty; and we soon discovered a fine patch of the rare Blechnum S. heterophyllum. This plant, as previously found, has been solitary, but here it had a sporadic character. We gathered some twenty or thirty plants, and left several for the next adventurers. After some time we took to the sides of the mountain, and there found the Calluna vulgaris, variety dumosa, with many other interesting plants, but which we cannot stop to notice.

The next two days were spent in an excursion and journey to Ben Lawers. The morning of the eleventh day we rose early. The clouds rested sleepily on the lower shoulders of the mighty Ben, not more than 1000 feet above the base; but we felt confident they would rise as the day advanced, and accordingly commenced the ascent by a route which, the day before, we had laid down as most eligible. Following one of the fences which run up the base of the mountain, we came upon a fine form of Blechnum near the B. caudatum of Moore, which was a good find of ours, in North Wales, some years ago. In this the cauda, or tail, was very blunt, therefore B. obtusicaudatum would be a more appropriate name. Then we came upon a fine patch of the White Mother Thyme (Thymus Serpyllum album). Well, up and up we go, and now we win the first shoulder of the mountain, and are fairly among the heather; but where are the clouds which rested here when we were at the foot of the mountain? They, too, have been creeping slowly up the mountain, and are still 700 feet above us. Higher and higher we go, and at every step we gain upon the clouds. It was not till we touched the base of the rock-crowned summit of the mighty Ben that we fairly encountered the fleecy vapours; but, oh! how delicious was the atmosphere—so soft, so pure, so warm and genial, that it was mildness itself! It was the most delicious cloud bath, and the greatest atmospheric luxury that we ever enjoyed. These clouds were not of equal density—some were thick and flocculent, others thin and attenuated, so that we had occasional glimpses of high and steep cliffs of mighty rugged masses of rocks, assuming all sorts of gigantic forms. By the occasional thinning of the clouds here and there we were enabled to make our way slowly up among the rocky heaps and steep cliffs.

As soon as we came to the rocks our astonishment and gratification began—we were in another world. The rocks (micaceous schist) showed an endless variety of distribution, form, and contour, and the surface of the ground and steep face of some of the cliffs were literally carpeted with the Alpine Lady's Mantle (Alchemilla alpina) over large areas. It was impossible to set down a foot without treading on this mountain gem. The upper surface of the leaves was a brilliant green, the under a shiny silvery satin. We almost shuddered at trampling under foot such beautiful verdure. Interspersed with the Alchemilla there was the still more rare Sibbaldia procumbens, and here and there dense silvery tufts of the dwarf Alpine Cudweed, Gnaphalium supinum. Up in the cliffs there were fine hoary masses of the Alpine Mouse-ear Chickweed (Cerastium alpinum), and, as the numerous hairs which clothe the whole plant were each terminated with a minute dewdrop derived from its cloud bath, it seemed almost like a mass of snow. Late as the season was, several of the plants high up among the rocky cliffs showed their large snow-white flowers. Its congener, the rare Cerastium latifolium, matted many of the little shelves among the rocks. The Alpine Meadow Rue (Thalictrum alpinum) was creeping among the Moss here and there, and showing its tiny Fern-like foliage, humble it is true, but not less beautiful on that account. Long lines of the Arctic Willow (Salix herbacea), not more than 1 inch in height, ran along the clefts of the rocks. There were large banks and patches of the little Moss Campion (Silene acaulis), its dense foliage packed so close together as to present the aspect of a mossy cushion; when in flower it is a vegetable gem of the first order. A companion to this, and imitating it in its mode of growth, but with still smaller foliage and more closely-packed shoots, was the Mossy Cyphel (Cherleria sedoides). As this was the first time we had seen this modest gem in its native home, and we believe almost its only British home, we were in an ecstacy of delight; but not this plant alone, but the multitude of others, now seen for the first time, yielded us many pleasures, and a new joy at almost every step, and we were kept in a constant thrill of astonishment and delight. Our spirits were exhilarated beyond measure; we were almost young again, giddy as a girl and buoyant as a youth let loose from school. It was impossible to feel hunger, thirst, or fatigue; the wading through miles of heather up the mountain's brow was nothing, and all our toils and difficulties were forgotten; and not a breath of air disturbed the delicately poised Bent-grass. The silence was deep and profound, save the faint murmur of a mountain stream, and the occasional distant croak of a raven. The only things which seemed to move were ourselves and the ever-varying clouds above, below, and around us, and we cared not for them so long as they retained their vaporous form. We were in the finest and the rarest alpine garden in Britain; we were very probably, though mere neophytes, treading in the steps of the botanists of old—Lightfoot, Don, Graham, Hooker, Brown, Greville, and a host of other worthies, who have made Ben Lawers renowned the world over.

We ascended higher and higher as the clouds permitted us to have glimpses of our course—zigzaging, now this way and then that; several times fancying we could see the summit, but when that was attained there was another point still higher; but as we rose the clouds became thinner, and by-and-by we left them below and stood on the top in a clear atmosphere. The vegetation near the top is very scanty, and the rare plants, Mosses and Lichens; of the latter Lecbanoras, Parmelias, and Gyrophoras were plentiful. But the one most interesting to us was the Solerina ochracea—seen for the first time. It is very striking, covering the loose stones with its leathery green rosettes, the under surfaces of which are of a rich golden hue. As we stood on the highest ridge we wished for at least one peep at the nether world, and waited for some time; but no, the fleecy masses, though occasionally thin, continued to obscure all beneath them. Once, and once only, through a nearly round hole in the clouds we got a glimpse of Loch Cat, on the eastern flank of the mountain. Passing slowly and cautiously down the western cliffs we came upon a depression or slight ravine—"corries" they are called in Scotland, and here the rare alpines were in rich profusion. The beautiful reticulated Willow (Salix reticulata) was very fine; the Saxifraga oppositifolia and miralis were abundant; and here we found what we had been long looking for—the vegetable gem of Ben Lawers—the Alpine Forget-me-not (Myosotis alpestris). We are told by good authorities that, when this plant is in flower, it is worth a journey to Scotland to see it, as the size and brilliant amethystine blue of its flowers gathered into compact heads, and the neatness of its foliage, render it one of the most beautiful of all alpines. When in flower it may be easily found, but now it requires to be looked for. It was nestling among the damp moss, on ledges of the rocks, among other rare denizens of this alpine garden; there also were found, in plenty, Polystichum Bonchitis, Pseudathyrium alpestre, and Lastrea dilatata alpina; also the companions to the exquisite Myosotis alpestris, the alpine Veronica, and Alpine Willow Herb (Epilobium alpinum).

We lingered long on this charming spot. The evening was drawing on, and we had to make a precipitate retreat. It was nearly ten o'clock when we reached our quarters.—(*Extracted from Mr. Stansfield's notes read before the Todmorden Botanical Society.*)

(*To be continued.*)

SHOWING VEGETABLES.

I am quite delighted to see vegetables taking the places which belong to them, although they are not so inviting as the beautiful Orchids and Roses, nor yet so luscious as Royal George Peaches, or the good old Hamburgh Grapes. Nevertheless, when we come to usefulness and health combined, I think your readers will agree with me when I say they are not to be placed beneath anything. Vegetable-showing is in its infancy, and I think proper regulations should at once be adopted to the satisfaction of all exhibitors, and if I may pre-

sume to give a few hints, I hope my doing so will be taken in good part by all.

I am sure you will admit that we Midland gardeners cannot successfully compete at such an early season as the gardeners of Cornwall and Devonshire. Take, for instance, the Carter cup at Nottingham last year. The Peas were full and good from the outh, but ours were not so, the reason being that the southerns enjoyed a better, warmer, and more congenial climate. I should like to know what is to be done to satisfy us all? I am sure your correspondents' great experience will be able to solve the problem.—R. Gilbert, *Burghley*.

AN AUSTRALIAN ADVENTURE.

The day was far spent as we neared a stream where we intended to encamp for the night, when "sounds of revelry" and boisterous mirth became more audible as we descended a hill. The noise and "rolicking-fun" soon after ceased, when the vocal strains of a fine tenor voice sang loud and clear the charming air and pleasant song,

"The maids of merry England, how beautiful are they."

The sentiment, so sweet and true, was harmoniously joined in by the party, whose voices commingled in the pleasing refrain.

As we listened to the once familiar words we felt certain that the voice of the singer was equally so, but when and where heard could not well remember. Our footsteps were quickened, as anxious "to join the jovial crew," we pushed onwards to the camp-fires, where a number of happy-looking mortals were enjoying themselves in various ways, which seemed to prove that there was such a state as rural felicity even in the forest shades of New Holland.

With but little ceremony we introduced ourselves as "travellers from Melbourne, on our way to Geelong," and were cordially welcomed to a share of their glowing fires and bivouac for the night. In the person of a handsome and gentlemanly fellow we fancied we recognised the singer whose song awakened thoughts of home and the loved ones there. Scarcely had we been seated, before our new acquaintance inquired, What part of England did you come from, and how long have you been away, and what are you doing now? Similar questions were asked and answered all round, when our interrogator somewhat surprised us with the information that his name was May, and was at one time in the nursery business near Bedale, in Yorkshire. "And my name is Harding, and well do I remember you when a young man, and in your father's employ years ago." The recognition was mutual when we referred to the time we heard him sing the same song he had just repeated, at a village party long ago. He, too, had not forgotten the time when bidding each other "good-bye" at the nursery gate, one cold December's morning, when, with "great expectations," we journeyed to the great metropolis, the centre in circumference of horticulture, where all young and aspiring gardeners aim for.

It was then, and may be so now, considered necessary to have a course of practice in and around London to qualify a gardener for a first-class position.

To sleep was out of the question; it seemed utterly impossible for anything mortal to slumber with the myriads of mosquitoes, fleas, ants, and other abominable insects torturing us in every way; so we passed the night in the smoke of the camp-fire, discussing "auld lang syne."

It was our good fortune to have fallen in with a party of "gum-pickers," who were gathering gum from the Acacia trees for exportation, and little inferior to the gum arabic of commerce procured in Senegal and the East Indies; from Acacia fera and A. arabica trees.

The varieties of Acacias are many, and number nearly two hundred species, indigenous to Australia alone; and are indispensable for greenhouse and conservatory decoration. Few, if any, flowering trees or shrubs are more beautiful or interesting than some of them. Such, for instance, as Acacia pubescens, A. conspicua, A. undulata, A. grandis, and A. Drummondii, grand beyond comparison. A. cultriformis, very curious; A. platyptera, A. Nielii, A. albicans, A. urophylla, so fragrant and pretty; A. amœna, a lovely gem; A. suaveolens, deliciously sweet; A. pulchella and A. spectabilis, beautiful indeed. These are but a few named of the many varieties, and all of easy culture. They will bear a good deal of hard usage and thrive moderately well, or perhaps better than most plants, in dwelling-house windows, and for setting-off a choice bouquet we know of nothing more graceful or pretty.—(*American Gardener's Monthly*.)

BATTLE ABBEY,

THE SEAT OF THE DUKE OF CLEVELAND.

When the Anglo-Saxons are named it is usual to associate their possession of England with the name of Alfred, to dwell on their triumphs over the early Britons and the Northmen, and to remember how they fostered the Christian missionaries in England; but when six centuries had passed they no longer retained the same characteristics, and one who has written their history tells that for the most part their sovereigns were feeble-minded, their nobles factions and effeminate, their clergy corrupt and ignorant, and the people servile and depressed. Thus England was becoming the possession of a debased, divided, and ignorant people. At this time of their decay the Normans came. Their dukes, though foremost as warriors, loved peace, their subjects were brave, united, and truthful; they were charitable, pious, lovers of literature, decorous, and moral. They conquered the Anglo-Saxons, and "from the mighty ruins with which the Conquest overspread the land, raised that great character of government—clergy, nobility, and people—which has since never ceased."

Knowing this we stood but a few days ago on one of the terraces of Battle Abbey, looked over the valley where eight centuries since the one decisive victory effected that conquest. Behind us—we were about to write "in our rear," for we had been reading of the strife until we had on our mind the military phraseology—was higher ground, and on it "The Watch Oak," marking where the Saxon sentinels looked out on the plain towards Pevensey on the movements of the approaching Norman host; and on Telham hill, beyond that plain, was planted the standard of the invading duke. Our feet were within the Saxon position. Harold's standard was here, near to it he was slain; the spot where he fell was covered by the High Altar of the Abbey, and the ruins of the altar's foundation remain.

We could dwell long and detail minutely the incidents of that bloody contest, but they are not within our province, and we may only note that the Conqueror had vowed, if victory was with him, he would build an abbey on the battle-field. He fulfilled his vow—

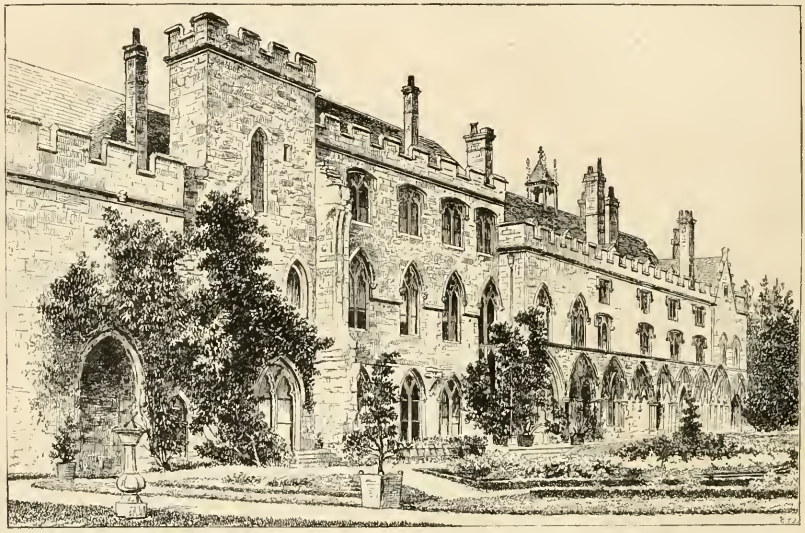
"And ther, as the bataile was,
An abbeÿ he lete rere
Of Seint Martin, for the soules
That there slayn were."

The Abbey was dedicated to the Trinity, the Virgin, and St. Martin, but this title, as usual, was popularly abbreviated, and it was known as "St. Martin's Abbey of Battle." Although commenced the year after the victory, the Conqueror did not live to see it completed, and William Rufus was at its consecration in 1094. It was surrendered to Henry VIII. when he abolished monasteries in 1538, and he granted, in the following year, the Abbey and the manor to his Standard-bearer and Master of Horse, Sir Anthony Browne. His son, created Viscount Montacute (erroneously spelt Montagu), demolished the chief part of the Abbey, and adapted the remainder for a residence; but the sixth Viscount, about the middle of the last century, sold it to Sir Thomas Webster, from whose descendants it passed to the family of the Duke of Cleveland. The Viscount was high in the favour of Queen Elizabeth, but we are not aware that she visited Battle Abbey. It is certain that she was entertained in the August of 1591 at Cowdray, the other residence of Viscount Montacute, and afterwards she was in the western parts of Sussex. The weather was propitious, and the company numerous, for it is recorded that the Queen frequently dined in the garden, that the table was 48 yards long, and that for a breakfast three oxen and one hundred and forty geese were provided.

We have endeavoured to give a slight historical sketch of Battle Abbey, but for a monastery so important and richly endowed, strange to say, comparatively little appears to be known of its history even a hundred years after its completion. Some parts of the building have evidently been built at a later date than the rest, and some are known to have been rebuilt by Sir Anthony Browne soon after the Reformation; but we are sorry to record the fact that little care seems to have been taken by former proprietors to preserve what at one time must have been, indeed still is, a noble and interesting building. Parts of it have been used as barns and granaries, and other parts lay long buried in the earth, or were suffered to fall to the ground. The entrance from the street of Battle is by a Norman archway and tower; eastward the

whole is lawn encompassed with belts of Laurels, Aucubas, Laurustinus, with tall Elms near the boundary; and beyond, the kept grounds merge into the extensive park. On the principal front, which faces the west, are trained fine plants of the Narrow-leaved Myrtle, Magnolias, Jasmine, and Garrya elliptica, the last covering a space 15 or 16 feet in height, and 12 feet wide. This shrub, of which a figure and notice are given in another column, was covered with its pale yellow male flowers in catkins as much as 9 inches long. So numerous, in fact, were they that the dark-green foliage was all but completely hidden by them. No one who saw such a plant could fail to recognise its suitability for covering a wall, and desire to see it more extensively employed for that purpose, being ornamental by its foliage and much more so by its flowers, especially when these are produced by a wall-trained plant on which, as at Battle, they appear to attain twice the length they do on shrubbery plants. Stauntonia latifolia, a greenhouse plant from China, trained against the same front of the house, had attained a height of about 20 feet, but had not fruited, though another plant had done so where the aspect was south.

What is supposed to have been the Guest House is a detached building covering an area 195 feet long and upwards of 40 feet wide, but all that remains of it are two octagonal turrets at the west end, and the niches of the windows at the sides, now used as seats, those on the south commanding a view of the battle field, Telham Hill in the distance, and on a clear day of miles of country besides. The space once occupied by the rooms devoted to the use of the guests and their attendants is now laid out in three neatly-kept grass plots surrounded by gravel walks. Considering that the religious establishments in early times served also as houses of entertainment for travellers, more especially those of the higher ranks, it is not surprising that so large a building should be devoted to their accommodation; and from the fact that beneath the



Battle Abbey—Cloisters.

whole is a range of cellars which even a great London wine-merchant might envy, it may be inferred both that the visitors were many and the cheer good. Of the dormitory, which runs north and south, and is 154 feet long by 35 wide, part of the walls are still standing, and beneath it are vaulted chambers, supposed to have been the living-rooms of the monks when not engaged on their religious or gustatory duties, for the performance of which last an ample refectory was provided. However, it is not for us to dwell upon these details, which belong more to the province of the antiquarian than of the horticulturist, but in a notice of such a place as Battle Abbey the remains of the past are so intimately connected with the present—in fact, serve as landmarks to it—that it is next to an impossibility to dissociate the one from the other. Nevertheless, we cannot but remark that those old masons had done their work well, not only in beautifully arched crypts, but in buttress facings, where their chisel marks remain fresh and clear at the present day, though the intervening work was of a rougher nature.

We have now reached the east side of the Abbey, where there is a garden laid out in small beds hedged-in by Box neatly kept to 6 inches high by 9 inches wide at top, with raised beds in the centre. The accompanying is a view of this side of the Abbey* with its cloisters, including also a portion of the garden referred to. In summer it is filled with bedding plants, and the broad Box edgings to the beds give it a unique appearance. We noticed here some remarkably fine Laurustinuses 18 feet high. The Laurustinus appears to luxuriate at Battle, flowering freely, and attaining a large size. The next garden is a square with an ancient Yew hedge 15 or 16 feet high, forming a dark, sombre wall on one side; Laurels and Sweet Bay nearly 20 feet in height are the other two sides. The ground within is laid out as a rosery, there being in addition a number of Camellias planted out, and two beds of Lilium speciosum (lancifolium of gardens) rubrum and album, which have been there for ten years; all the protection given is a covering of ashes over the bulbs in winter. At the back of the Yew hedge referred to is a row of Yew trees equally ancient, and the branches of the two form a Gothic arch over a walk running the whole length of the back of the walk, and in some cases the branches are naturally inarched. This walk has a quaint, rustic character, as well as being venerable by its age. The Monks' Walk, parallel with the boundary wall, is also interesting, and from the raised walk on the wall one can see miles of the surrounding country. Just pausing to notice another Yew-bordered walk, the trees not so old as by that previously noticed, we come to the site of the High Altar erected on the spot where Harold fell, and near which are several magnificent old Cedars of Lebanon, and a fine Deodar about 40 feet high. Her Grace has herself tastefully planted Ferns and herba-

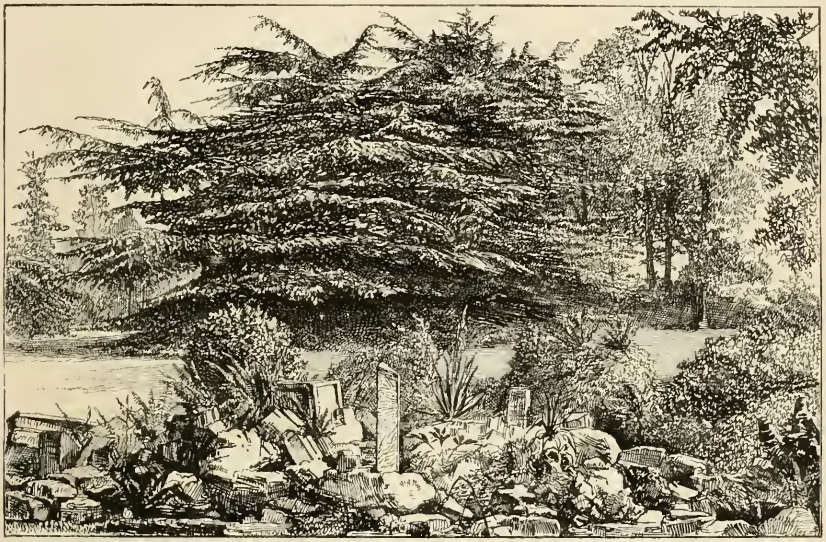
* The two views which we give were obligingly furnished to us by Mr. Mann, Photographer, of 13, Wellington Place, Hastings.

ceous plants among the ruins at this interesting spot (of which we give a view), as well as elsewhere in the grounds. A little further on we come to a picturesque walk with fine old Lime trees on one side, and behind these is a rustic ice-house, which holds about one hundred loads, and keeps the ice in excellent condition throughout the season. Here a heathery is being formed, and beds of hardy Azaleas have been planted as kindred subjects. A few Gladioluses are put in to give life in summer.

On the south side of the Abbey, where the old stabling, offices, and houses were, the ground has been converted into lawn and planted with Araucarias, Pinus insignis, Wellingtonias, and other Conifers, which are in a thriving condition, and some of them are already fine specimens. A new drive to the station has also been formed through this part of the grounds, the only drawback being that portions of the village are too plainly visible in parts, but this will be remedied in time by the growth of the trees which have been planted as a screen.

On the south side of the Abbey a new terrace 180 yards long has been recently formed. The place of a terrace wall is supplied by a dense low Holly hedge 3 feet wide at top, with standards on 6-feet stems at every 30 feet. Along the walk next the hedge, and rather interfering with its line in one or two places, are three fine trees of the Scarlet Thorn, but though, as stated, they interfere a little with the walk, the trees have been wisely preserved; it would, indeed, have been a pity to have touched such fine old trees, so beautiful, too, when in blossom.

Ascending to another terrace we reach a walk 14 feet wide and 200 yards long, with, on the side next the park, we believe, the finest Laurustinus hedge anywhere to be met with. It is 4 feet high and from 6 to 8 feet in breadth, with standards at every 30 feet or so, and is perfectly furnished from bottom to



Ruins of High Altar.

top. It must be a beautiful sight when in flower. Here there are compartments for bedding plants, of which from 25,000 to 30,000 are required. The walls of the Guest House, which is at the back of this terrace, are covered with Monthly Roses, Oleanders, and Clematises, and when the Roses are in blossom the effect must be very fine. But more noteworthy than the Roses are several plants which elsewhere are kept in greenhouses. Among these are Stauntonia latifolia more than 20 feet high—this fruits well; the Pomegranate, which flowers but does not fruit, Mandevilla suaveolens covering 25 feet of wall, and Poinciana gracilis. As a measure of precaution, these, Coronilla glauca coming into flower, Aloysia citriodora, and some others of the more tender subjects, were covered with spruce branches. That useful early-flowering Jasminum nudiflorum unfortunately a scentless one, was gay with a profusion of its golden blossoms. The terrace walk terminates at a gateway flanked with two handsome specimens of Cupressus macrocarpa.

We next enter the conservatory, in front of which are a set of beds that are kept gay in summer with Clematises and bedding subjects. This conservatory is upright-sided, with a half-curvilinear roof, and measures 71 feet in length by 17 in width, and the same in height. Great credit is due to Mr. Jack, the excellent gardener, for the gay appearance which it presents, more especially as he has not a great extent of glass from which he can draw unlimited supplies of plants. Among the inmates were some fine pyramidal Camellias standing 8 feet high blooming freely, Azaleas, Epiphyllums grafted on Pereskia stocks so as to form standards 2 to 3 feet high, Begonias, Epacrises, and an excellent collection of miscellaneous flowering plants. Tacsonia Van-Volxemi is trained on the roof for shade, and among other climbers Lapagerias, Stephanotis, Passiflora princeps, and Fuchsia corymbiflora. Two very fine specimens of the Abyssinian Banana, Musa Ensete, in tubs, give a tropical air to the house, not the least notable ornament to it being handsome Orange trees, one of which in particular was loaded with rich golden fruit, not sour half-ripened fruit, but fit for the dessert.

Before quitting the pleasure grounds we must notice a new walk being made, skirting the park and passing through a well-wooded portion of it between the trees and Ivy-covered banks. This when finished will be upwards of half a mile long, and will, no doubt, add a fresh charm to this old place.

The kitchen garden, including the outside slips, is two acres and three-quarters in extent, and is new, having been made since Mr. Jack came to the place, the old garden being now an orchard and used for growing early Potatoes, &c. The walls are English bond, 14 inches thick, 12 feet high, and surmounted by a coping projecting 8 inches. The Peach, Plum, Cherry, and Pear trees are trained with great neatness and care, and look very healthy and fruitful. Apricots, however, are apt to die off in the unaccountable manner so often complained of.

The vineries are three in number, in addition to which there is a Peach house. They are all lean-to's, 30 feet long by 12 wide. The Vines are all planted inside, but the front walls being arched the roots can pass outwards. In the early vinery Mr. Jack had grafted on one Vine the Golden Hamburgh, Muscat of Alexandria, and Canon Hall Muscat, but he found that the Muscat of Alexandria had robbed the Golden Hamburgh. Mr. Jack states that by notching the wood of the Canon Hall he finds it sets as freely as the Royal Muscadine. The trees in the Peach house are trained on a curved trellis in front, and on the back wall as well. They looked healthy, and gave promise of bearing an abundant crop.

The other houses consist of a span-roofed Cucumber house 30 feet by 9, and 9 feet high, heated by two flow-pipes one on each side, and two returns one under each bed. Besides Cucumbers, Dwarf Kidney Beans and Asparagus are forced, the former in a heated pit and in the Peach house as well, though not desirable inmates for such a structure, and Mr. Jack would gladly dispense with them there. The other pits are filled with bedding plants, Lettuces, Cauliflowers, &c. There is a Mushroom house, heated by a 3-inch pipe, in which fine crops are obtained, especially from the beds on the floor; Sea-kale and Rhubarb are also grown here. In the fruit-room, which contained more fruit than some even in larger gardens, we noticed that the fruit was laid on dry Fern spread over the open-slatted shelves, and in this way it keeps exceedingly well.

We have only to add that the out-door crops and general keeping of the place were most creditable to our friend Mr. Jack, the careful and painstaking gardener, and we take this opportunity to thank him for his kindness and the trouble he was at in pointing out all that might interest us and our readers.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The preparation of the quarters intended for main crops must be persevered in whenever the soil is dry enough to admit of its being trodden on without being too much consolidated. This is of great importance in the case of heavy soils, and those who have such to deal with should take advantage of every dry day to prepare them. It will also be advisable to defer sowing main crops for a week, or even a fortnight. On light dry soils, on the other hand, the sooner the main crops are in the better, because such soils are most liable to suffer from drought should it occur; therefore the sooner the crops can be well established the better will they resist dry weather. If, on the contrary, the season is wet they will be in the best possible condition to profit by it. Make a small sowing of Grange's Early White *Broccoli;* the sowing made now will come in useful by-and-by. Sow another patch of early *Cabbage*, also some Red Cabbages for winter supply. Prick-out the young seedling plants of *Cauliflowers* and *Lettuces* either on a warm border or a gentle hotbed, and shelter them for a time with hoops and mats. The first sowing of *Celery* must also be pricked-out as soon as it can well be handled. Make a first sowing of the true Drumhead *Savoy*. Sow a good breadth of the best Curled *Parsley*. On light soils lose no time in getting in the main crops of *Peas* for summer, together with a few of the later kinds. The ground on which the Peas are sown comes in well for Celery, a width of 6 feet being allowed from row to row; but this distance might be increased with great advantage, and the intervening spaces sown with *Spinach*, early *Turnips*, *Radishes*, and *Lettuces*, all of which would come off in time for the Celery.

FRUIT GARDEN.

Pruning should now be quite finished in every department, and whatever nailing is left undone must be completed immediately. See that new-planted fruit trees are properly staked and mulched, and after high winds it is necessary to look round them and press the earth gently to the base of the stems. All danger of very severe frost being over, Figs may have the covering completely removed, and be neatly pruned and nailed. Do not crowd them with wood.

FLOWER GARDEN.

The digging of flower borders must now be commenced in good earnest, in performing which use the fork in preference to the spade. All kinds of herbaceous plants may now be planted, either to fill up empty spaces, or to make new plantations in borders which have undergone a course of preparation this season. Pay particular attention to the arrangement of the plants according to height, and colour and succession of flower. Bear in mind that a profusion of bloom alone does not make a flower border beautiful and attractive, unless the plants are disposed in such a manner that harmony of colouring may prevail throughout the whole. Proceed with the planting of hardy Roses. If the plants are strong prune their heads according to the classes to which the varieties belong; if weak, cut them back to two or three eyes, shorten all long and straggling roots, and prune away such as may be bruised or broken. If the ground has not been prepared as previously directed I would recommend pits to be made, and to two pits give a wheelbarrowful of rotted dung and good loam, well mixed. By all means avoid deep planting. Have a quantity of stakes and tar-twine close at hand, and stake each plant whether it is a dwarf or standard; many losses are incurred and much injury sustained when this is neglected. Continue the pruning and nailing of climbers, also arranging and tying such as are against trellises, verandahs, &c. Due attention must be paid to the sweeping and rolling of walks and turf. This should be done at least once a-fortnight at the present season. Those walks which have become dirty upon the surface and are overrun with moss should be turned to the depth of 2 or 3 inches. By this means they will have the appearance of having been newly made. The beds of Tulips being great favourites of the amateur will now require great attention, the foliage being generally well above the surface, and consequently liable to the vicissitudes of our changeable springs. At this season a rainy day is often succeeded by a sharp frost, or hailstorms mercilessly pelt the rising plants. Some florists think it is of little use to cover, supposing the Tulip to be sufficiently hardy; but when the leaves form a kind of cup which holds a considerable quantity of water, which in a frosty night is turned into a mass of ice, enveloping the rising bud, I think it will be allowed that protection in this case at least is advisable. It is desirable to stretch a thin calico over the bed at night if frost is expected; this will be found sufficiently effective. Canker will often make its appearance on the foliage; this must be carefully removed with a sharp knife, exposing the part as much as possible to the air, but keeping a shade over it for a few days. Now is a very trying period for Carnations and Picotees; many layers that have apparently withstood the winter with impunity will often wither and die, and if examined they will be found not to have made a single fibre since they were potted last autumn, showing the propriety of early potting, in order that the plants may, by being thoroughly established, be enabled to stand the weather. Continue to shade the rising blooms of Polyanthuses on seedling beds. If pin-eyed flowers show any good property in a marked manner, cross-breed that variety and save seed from it.

GREENHOUSE AND CONSERVATORY.

We have previously recommended the removal of plants from various houses, to aid in embellishing the conservatory; their beauty past, they must no longer be allowed to remain, but should be restored to a situation suitable to encourage a healthy growth, and consequently an assured provision of flower-buds for a future season. It is a great advantage to possess a pit which can be appropriated to this purpose. When it is found that plants are much exhausted by early forcing they should be supplied with fresh and suitable soil. Allow no essential variations in the temperature; 60° should be the average. The occupants of the greenhouses will require from time to time increased pot-room to follow the extension of the leaves and branches. Fuchsias, Pelargoniums, and Calceolarias must receive the benefit of this rule.

STOVE.

In this structure much is to be done every day. The plants of Poinsettias, Euphorbias, Clerodendrons, Aphelandras, Gossypium, and Gesnera oblongata and longifolia that have previously been cut down and are now breaking should be shaken out and repotted in good, open, rather light, fibrous, turfy loam, coarse sand, and a good portion of charcoal, which all plants delight in. Prick off carefully into small pots, as they appear in the store pots or pans, the various kinds of Achimenes, and put in another batch, likewise various Gloxinias. The whole of the above delight in a moderate bottom heat at this season. See that the plants of Gongoras, Stanhopeas, some of the beautiful Dendrobiums that are now making their season's growth, are not suffering from want of water; it is sometimes found essential to soak them once or twice in the tub of tepid water. Syringe carefully about the blocks and baskets that have plants of Vandas, Saccolabiums, Sarcanthus, &c., growing or adhering to them.

PITS AND FRAMES.

Pot off into 3-inch pots plants of the Bouvardia triphylla and splendens which have been raised from small portions of the roots; replace them in a kindly heat. Those who have not as yet attended to the propagation of plants for bedding-out, must now begin with all possible speed to put in cuttings of Salvias, Petunias, Fuchsias, Verbenas, Scarlet Geraniums, &c., so as to have good plants for bedding-out in May. Pay due attention to watering and topping-back weak and straggling shoots, so as to form robust bushy plants. If snails or slugs have found snug quarters in this department they will do much mischief during the mild weather, if not looked after and destroyed.—W. KEANE.

DOINGS OF THE LAST WEEK.

Preserving Seeds from Birds, Mice, &c.—At one time I found it vain to expect an early or even a second crop of Peas unless I planted them out when the plants were from 3 to 5 inches in height. Even before the Peas reached that height wire netting proved ineffectual, as the vermin got in one night and spoilt some rows. I found that coating seeds of all sizes with a colouring of red lead saved them from the attacks of all intruders. This season, however, the rats have been most unmerciful on a piece of Beans, notwithstanding the usual red colouring, in consequence of a number of changes here, which have rendered us more liable to their visitations.

Sowing Seeds in wet soil. In unusually wet seasons like the present seeds should not be sown too deeply, nor covered up excessively in stiff soils, as in that case they are almost sure to rot. We have known whole rows of Peas never come up at all, in consequence of having been too deeply sown. We certainly approve of sowing Peas and Beans in a somewhat deep furrow, but then the seeds are covered very slightly—not more than from 1 to 2 inches in such a season as this. In extreme cases we can, in the garden, pat the seeds gently into the ground, and cover them over with some fine dry material. Moist soil beneath and rather dry soil above are, perhaps, the best of all conditions for a free healthy germination, as the moisture swells the seed, the air gets access to it, and the covering keeps out the light. We know there are seeds which, if they have moisture, will germinate in full sunshine. We are, however, convinced from our own experience that many seeds are much injured by free exposure to sunshine before they are sown, whilst many more are injured by being sown and covered too deeply in moist soil, so as to exclude the air as effectually almost as if they had been surrounded with a piece of putty. Sow, therefore, in well-stirred, well-aired, rather dry soil, and the rains will percolate freely, and the seed and seedlings will be benefited rather than otherwise. We have known instances in which different gardens were supplied by the same seedsman, the seeds taken out of the same bag, drawer, or paper, saved and stored at the same time, and therefore as much as possible alike in quality, and yet almost totally unproductive in one case, and perfectly good in the other.

The same fact holds true with respect to all our more artificial sowings in pots and boxes under glass, such as those of Lobelias, Calceolarias, Chinese Primulas, and Cinerarias. I do so thoroughly believe it to be the true interest of our seedsmen to send out the best article they can command, that when I have anything like a failure, instead of blaming a tradesman, I think it better to inquire if there has not been carelessness and inattention on my part.

One of the chief secrets of success, therefore, in sowing, especially under glass in pots, and when using such small seeds as those of Calceolarias, is to have the soil beneath moist enough to secure germination and rooting, and the covering fine and rather dry. When sowing any of these small seeds, or larger seeds, as Primulas, &c., drain the pot or pan well fill it with three sorts of soil, the roughest at the bottom, the finer above that, and finest at the top, pressing it down so as to be within an inch of the rim. The pots are then thoroughly watered, or set in a tub of water until all air-bubbles cease. This secures a thorough moistening. The pots then stand to drain for twenty-four or thirty hours, when the surface will be a little dry. Some dry sandy fine soil is scattered thinly over and slightly pressed, the seeds are then sown, another slight sprinkling given and pressed level, a square of glass put over the pot, and the glass shaded. In many cases, when the pot is set in a bed, the seedlings will be up and strong before any watering is wanted.

One word more as to the safety of such small seedlings. If moisture is needed avoid watering overhead, but sail the surface with water by pouring it on a tile or shell near the side of the pot. Give moisture by any mode, except pouring it over the top of the young plants, however fine the rose be, and you will take the best means for preventing seedlings that come up thick foxing, or rotting, or shanking-off at the surface of the soil. Another preventive is to prick-off these seedlings as soon as you can handle them, singly or in little patches, as the patches may be divided singly or in pairs afterwards. Many a fine pot of valuable seedlings has been destroyed by a careless overhead watering.

Cucumbers in hot-water pit versus those in frames with fermenting material beneath them.—As respects the earliest spring-planted Cucumbers, we have amused ourselves in holding the balance evenly, and for years there was little to draw between the two modes. This year the pit will have all the first running, as we have only turned out good strong plants in the frames on the 22nd, whilst those in the pit are running and showing freely. For the benefit of beginners I may mention the causes of delay, the plants being nearly of the same age. First, we made the beds a little later than usual; secondly, the want of sun heat, and the more free use of leaves, kept the heat from rising sufficiently; and thirdly, this was partly owing to the mode we have more than once described of putting all the soil we require into the bed at once—a mode attended with much future economy. The frames we have left average 16 inches in depth at back, and 10 inches in front. These, therefore, to give ample room to the foliage, are above the level of the soil. The frame stands upon a wide ridge all round, leaving a trench in the middle 16 or 18 inches in depth, and from 24 to 28 inches in width. A board is placed lengthwise at the back and front of this trench, between which the soil is placed; the boards on each side confine the roots and prevent them running into the decomposing material at the sides. In this dull weather it took more time than usual to heat this trench of cold soil, but when the inside temperature showed 60° in the morning, and the soil was nearly 80°, we planted. As regards simplicity there are several advantages in this mode. A shallow box can be made to answer the purpose. Only about one-third of the quantity of soil is required when contrasted with a bed earthed over in the usual way. The earth is put in at once, and there is no anxiety in watching and waiting for a favourable time for earthing-up the plants bit by bit, and very likely injuring them more or less. The earth thus sunk is placed on the lowest level of the bed, and therefore there is scarcely any likelihood of root-burning, that evil from which so many beginners suffer, whilst the fermenting material round the trench keeps the roots comfortably warm. Lastly, the limited soil and the curbing of the roots by the boards tend, truly, not to huge parasol leaves, but to an abundance of good Cucumbers.

We have satisfied ourselves over and over again that a width of from 24 to 30 inches of soil in the middle of a 6-feet-wide frame, with a few rich surfacings during the season, will yield more Cucumbers than if the soil had been 6 feet wide. Our most prolific crops, even in hot-water pits, are chiefly owing to the little room given to the roots.

Heating Pits and Houses by Hot Water.—In answer to many inquiries, we would remark on our experience of the importance of not being too sparing of piping. Some tell us how soon they can make the water boil in their pipes, and the great heat thus given off. We think it much better never to have the water in the pipes within some 30° of the boiling point. I have several times alluded to the superiority of little houses over pits, chiefly because one can work in them. Another advantage is that they contain so much more air that the temperature is less liable to sudden changes. In addition to these advantages, a lean-to Cucumber house, or a span-roofed one with an inclination steeper than 45°, has a great advantage in the winter months over a pit, owing to the greater amount of light presented to the plants. Our present little Cucumber pit was originally a common pit 6 feet in width, 3¾ feet above the ground at the back, and 1½ foot in front. We made a little house of it by forming a sunk pathway at the back 18 inches wide, and 7 feet from the floor to the top of the wall, and ran a wall along to make a bed in front. Now what we want others to profit by is our faulty example. We had two 3-inch pipes laid in rubble for bottom heat, and that does well, but we only had two for top heat. Such piping would do very well with little or no protection to the glass from March to November. But for winter Cucumbers we could not safely make it do without a

covering of the glass at night, and protecting the back wall with a thatching of straw, or even at times placing a lining of fermenting material against it. To be safe without such covering in midwinter we would need double the piping for top-heat. If we were to do the work over again we would use 4-inch pipes, two beneath, and at least three above for top heat. The more confined the space the more will Cucumbers suffer in winter from having the heating pipes over-warm. Many people think they are very economical if they can save a few feet of piping. Whenever pipes must be made very hot the economy is actual waste. We know of many instances where in moderate-sized houses the saving of 40s. in piping has occasioned the spending of more than that for additional fuel every year, and then the enclosed atmosphere was anything but so genial as a further supply of pipes, and these less heated, would have rendered it. We have made our pit do very fairly, but with more piping we would have saved extra labour and care. We could furnish more examples to the same effect.

Our general work has been chiefly a repetition of what has lately been alluded to in detail. In the kitchen garden we took the opportunity in a dry day of sowing Peas and Beans, and planting Potatoes on a raised bank, and in such mild weather giving more air to these and other things in pits and frames.

In the fruit garden, besides pruning and washing out of doors, we were engaged in cleaning and washing the walls of the orchard house and late vineries.

In the ornamental department, besides moving and transplanting out of doors, we have done much potting inside, and examined and repotted as needed Camellias that had begun to make fresh growth after blooming. Most Justicias, Eranthemums, and similar plants have been pruned back and placed in a rather cool place to break afresh, when they will be repotted in the same-sized pots. Poinsettias have been laid down beneath the stage in a cool house to keep them alive, and allow them to become dry before pruning them back. Many plants of a similar nature require little trouble until they begin to grow. Few things in winter are more gorgeous than huge heads of these Poinsettias. Even when a head begins to fade, the leaves that are fresh come in well for dressing. For fine heads there must be strong stems. We have had some little plants in 4-inch pots with two or three small heads, and the plants only from 6 to 9 inches in height, that looked very nice. The heads, of course, were small. Potted Gloxinias to obtain the flowers for dressing.—R. F.

TRADE CATALOGUE RECEIVED.

George Yates, 23, Little Underbank, Stockport.—*Descriptive Catalogue of Select Vegetable and Flower Seeds.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Peach Blossoms Falling (*Peach*).—The hearing wood was not thoroughly ripened, either from being over-shaded or ill-ventilated in the orchard house.

Maréchal Niel Rose-buds (*B. D.*).—We should advise you to leave the young buds and cuds of the Maréchal Niel on some of the strongest shoots for the sake of experiment, as, if the weather do not soon materially alter, the buds may come to perfection. Thin out weak shoots, and shorten only slightly the stronger ones on which you do not leave the buds. As a rule, Maréchal Niel does not require much pruning. Our weather of January and February of this year is equal to that of March and April of last year.

Mr. Fountaine's Fruit House.—"In the report of the Horticultural Directors, page 141, it is stated that in the Rev. Mr. Fountaine's house at Cliswick, where the Madresfield Court Grape was so successfully grown by Mr. Barron, there is no provision of any kind for artificial heat. Will you kindly state, to prevent mistakes, that although the heating apparatus has not yet been applied to the Cliswick house, artificial heat is necessary for growing properly stone fruit, flowers, and Grapes in these vineries, and they are prepared accordingly ?—John Fountaine."

Twelve Good Varieties of Potatoes (*K. M. H.*).—Hogg's Early Coldstream, Turner's Union Round (early rounds); Mona's Pride, Myatt's Prolific (early kidneys); Daintree's Seedling, Dalmahoy (round, second early Regents); Rivers's Royal Ashleaf, or Veitch's Improved Ashleaf, *Almond's Yorkshire Hero (second early kidneys); *Gryffe Castle Seedling, *Rintoul's New White Don (round, class Regents); *Paterson's Victoria, *Dean's Excelsior (kidneys).

The asterisks denote good keepers, and sorts which require to be planted 3 feet 6 inches apart row from row. Good coloured sorts are Paterson's Scotch Blue (round, second early); *Paterson's Alexandra (kidney, late); and *Dean's Cottagers' Red. A Potato fit to displace Hogg's Coldstream is a new sort which the Messrs. Veitch are just sending out, called Veitch's Early Perfection. Fenn's Onwards, by the same firm, is also a second-early garden variety of good quality. The much-vaunted American sorts are no longer grown by me. I cannot recommend them for table purposes. As great croppers or for very poor, sandy, light soil they may be approved.—Robert Fenn.

Lightening Clayey Soil (*Lobelia*).—Lime, chalk, bricklayers' rubbish, coal ashes, and sand, one and all, if mixed with your soil will render it more friable; but the most effective treatment, and at the same time destructive of weeds and vermin, is to pare and burn the top spit of the entire surface, and to spread and incorporate the ashes with the next spit.

Summer Use of Garden Frames (*F. J.*).—The most profitable crop would be Cucumbers, and there is no necessity for more than a moderate bottom heat, so as to give the plants a start. Though there is a hard bottom, we do not know why you should not put in a depth of 12 inches of fermenting dung at the back, gradually sloping it to 8 inches in front, treading firmly, and put in 9 inches of soil at the back and sloping it so as to be 4 inches in front. If you were to have a wood partition you might employ two lights for Melons. The soil for the Cucumbers should be a good, rich, light loam, enriched with leaf-soil or old manure; and for Melons strong loam to endure firm is most suitable. The seed should be sown early in April, in a brisk bottom heat of 70° to 75°. When the plants show their rough leaves they should be potted-off in pairs in 3 inch pots, and be returned to the hotbed. When they have made two rough leaves, take out the points of the plants. The frame should be prepared a week previous, so that the soil may be warmed for the reception of the plants at the beginning of May. One plant will be sufficient to put under each light, selecting the better of the two and cutting the other away. If the frame is not clear of bedding plants by that time, you have only to time it so that the plants will be a month old when you have the frame ready. You may have Cucumbers in about six weeks from planting, and they will continue to produce up to October. You may have Melons at the end of August or early in September. Ne Plus Ultra Volunteer is a very abundant-bearing and excellent Cucumber. Gilbert's Improved Victory of Bath Melon is a fine green-flesh, Heckfield Hybrid is also a free-bearing sort.

Tacsonia Van-Volxemi Culture (*Tacsonia*).—Merely thin out the long and bare shoots, leaving the shortest and strongest, especially those from the base of the plant. Leave a good number of shoots for training-in, and what you do prune cut to within a joint of the plant whence they originate. Remove the surface soil, not going so deep as to injure the roots, and replace it with a 2-inch depth of loam from turf, leaf soil, and well-rotted manure in equal parts. Water with liquid manure once a-week from May to September, taking care not to use it too strong.

Ficus elastica Culture (*W. H.*).—The lower leaves have probably fallen from old age, for though the plant is evergreen, the old leaves fall when new ones are formed. If your plant is taller than you wish, you may cut it down as low as you like, and it will break again freely. The part removed may be made into cuttings, taking the end with two joints and the growing point, and the rest may consist of two joints each, removing the leaf from the lowest joint and cutting across below it. Insert the cuttings singly in small pots, in a compost of two parts sandy loam, one part sandy peat, and one part silver sand, making a hole for the cuttings in the centres of the pots, and dropping a little sand in the hole; then introduce the cuttings and fill all round with silver sand. Place the pots in a brisk bottom heat of about 75°, and a top heat of 65° to 75°, keeping close, moist, and slightly shaded from bright sun. When rooted remove them to a stove or vinery at work, potting them in larger pots as those they are in fill with roots. The plant may also be propagated by eyes. In winter it requires to be kept rather dry, and in a temperature of 50° from fire heat.

Forcing Pit (*J. G.*).—The manure or leaves should be changed about every six weeks, placing some fresh on the top every ten days, in order to keep it to the height required. Of course, there is no necessity to change the fermenting material so long as it retains sufficient heat, and one side only should be changed at a time, so that the plants may receive no check, as they would do were you to remove both linings at once. The space under the bed should be filled with hot dung or fermenting material. 10 inches of soil should be provided for the Cucumbers or Melons, and its surface should be about 15 inches from the glass.

Musa for Warm Greenhouse—Areca lutea (*Omega*).—Musa assamica, a dwarf-habited sort from Upper Assam, would do; also M. Cavendishii and M. Eusete if you have room. Areca lutea we do not know, but A. lutescens is in most of the principal nurserymen's catalogues. It would thrive in your greenhouse.

Colours of Geraniums (*Pro Bono Publico*).—1, Mrs. Pollock, leaves green; zone bronzed red, dashed with crimson, golden margin; flowers crimson scarlet; 2, Christine, light green leaf without zone, flowers rosy pink; 3, Attractive (new), we have not seen; 4, Amy Hogg, light green leaf with faint zone, flowers bright purplish rose; 5, Buijo, leaves green with rosy scarlet flowers. The best use for a frame 8 feet long and 3 feet 6 inches wide would be planting it with Cucumbers or Melons. Two plants of either would be sufficient. The frame would be very useful for raising plants from seed and for cuttings, and might afterwards be used for either Cucumbers or Melons.

Climber for North Wall (*F. H.*).—The wall being a high one, we should advise Virginian Creeper or Clematis Vitalba. If you wish for an evergreen, Ivy is most suitable. If only a low wall, then Jasminum nudiflorum or Cotoneaster microphylla, the latter an evergreen.

Lilium eximium Thinning (*A Constant Subscriber*).—Do not remove any of the shoots, but top-dress with rich compost without delay. The bulbs are not weakened by the shoots not flowering; on the contrary, they are strengthened; in fact, the better leaf-growth you secure the better is the prospect of flowers another year if the growth is well ripened.

Select Camellias (*C. B.*).—Fimbriata, white; Mrs. Abbey Wilder, white, striped with carmine; Valtevaredo, rose; Wilderi, rose; Storyi, rosy pink;

GARDENERS' EXAMINATIONS (*A. E. J.*).—Gardeners may be examined by the Royal Horticultural Society of London, and you will be furnished with particulars if you write to J. Richards, Esq., Assistant Secretary, Royal Horticultural Society, South Kensington. The great advantage of passing honourably such an examination is, that it is known that you have a theoretical, and so far a practical, knowledge of gardening. If there has been a disadvantage, it has been from the fact, too general, that young men cram for such examinations, are apt to trust too much to certificates, and hence to be outshone in practice by plodding attentive men, who have far less real scientific knowledge. The test is results.

VALE ROYAL (*Constant Subscriber*).—We had no scale.

GARDENER AND HELPS (*M. Denton*).—We should say, at a random guess, that three men would be required for such a place, but much depends on the quantity of grass, how it is kept, and on the means for keeping the conservatory gay in winter, as there seem to be little means for that purpose, except the Melon and Cucumber house. Pleasure grounds can give no definite idea. According to the grass and beds, one place of the same size may require three times more labour than another. Then there is such a difference in keeping a place tolerably neat, and having it always in first-rate order. We have known places such as you describe managed by two men. We have known places of similar size underworked with six men.

BULB SHOW (*Coleus*).—We know of none except those at the Royal Horticultural and Botanic Societies.

VINE FOR STABLE-YARD (*A Regular Subscriber*).—If the soil is not a light friable loam it will be necessary to remove it to a depth of 3 feet, but if it is so it will only be necessary to take care that water does not lodge. If wet, drain the ground efficiently, and trench it 2 feet 6 inches deep, mixing with it a moderate amount of manure and some old lime rubbish; or, failing that, broken sandstone or freestone. If the soil is very strong take it out to the depth of 3 feet for about 6 feet in width, placing 9 inches of drainage at the bottom—any stones or brickbats will answer—and below these there should be a drain. The border may be formed of the top 3 inches of a pasture, the soil a light loam, and to every ten parts of this add four of lime rubbish from an old building, two of manure, one of charcoal, one of crushed bones, and two of sandstone or freestone not broken very small, but without removing the small parts. Mix the whole well, and then place it in the border, 9 inches higher than the intended level, to allow for settling. You may cover the border with gravel, but it is well to leave a foot of it bare or 18 inches next the wall. Black Cluster or Royal Muscadine is the variety we would plant. Of either you can procure a Vine with a cane the length you name, at any of the principal nurserymen, but we would not plant until the Vine had begun to grow; then turn it out of the pot, spread out the roots, and cover them about 6 inches deep with fine soil, giving a good supply of water at a temperature of 70°.

ROSES—MANURING, &c. (*T. W. W.*).—I did not speak of superphosphate, but of nitrophosphate blood manure. I advise you to pulverise the nitrophosphate, but as much as a man can hold in his hand into three gallons of water, and pour the contents over the roots of six plants. That is how I use nitrophosphata. Put the stuff on when the plants are in a growing state. Cut down some of the naked stalks of Marguerite de St. Amand and Madame Clemence Joigneaux close to the ground, and merely shorten the other long stems by instalments. Cut down closely all your pet growers. Gloire de Dijon could not have given cracked blooms for want of water last season. You should have stirred the ground, it is a good plan whether the season is wet or dry. I keep the hoe going among my Roses. Charles Lefebvre is a fine grower here. I have at least 170 plants of it on Manetti—all good growers. I consider Charles Lefebvre and Maurice Bernardin, taken at all points, to be the best among crimsons.—W. F. RADCLYFFE.

PRUNING MARÉCHAL NIEL AND SOUVENIR D'UN AMI ROSES (*St. Edmunds*).—They do not require to be cut hard. If their wood is weak and bad, cut them down tolerably closely, otherwise only cut out the weak wood and shorten the remainder a little.—W. F. RADCLYFFE.

PETUNIAS IN POTS (*An Amateur*).—You do not say in what size of pot your plants are, but we presume them to be in 3 or 4½-inch pots, and to have been stopped; if not, stop them now to about four joints. You will thus secure two or three shoots. Shift the plants when the shoots are an inch long into 6-inch pots, and when the shoots have three joints take out their points, and again whenever those resulting from the stopping have grown to that extent, up to within ten weeks of the time of exhibition. Have the plants in their blooming pots by the middle of June, shifting into 8-inch, and finally into 10-inch pots. The drainage should be good, and the compost may consist of two parts light fibrous loam, one part leaf soil, half a part of old manure, and a quarter of a part of charcoal, from the size of a pea to a hazel nut, and silver sand, well mixed, but not sifted, though it must be broken small. Water moderately, and only when dry, but before the foliage flags, and then give a thorough supply. When the pots are full of roots weak liquid manure may be given at every alternate watering. Keep the plants in a cold pit after April, not more than 16 inches from the glass, and admit air abundantly, excluding frost. In mild weather the lights may be drawn off after May, but when the plants are advancing for flowering the lights will be needed to protect them from heavy rains, yet admit air abundantly. To have Gesnera zebrina in good order at the time named, start the plants at once, and grow them in a brisk heat with plenty of moisture.

BOILER FOR GREENHOUSE (*A. Aitken*).—Our opinion is that not one beats a saddle-back boiler. If not much more than 3 feet in length we prefer cast iron. If much larger we prefer wrought iron, but we have no great preference.

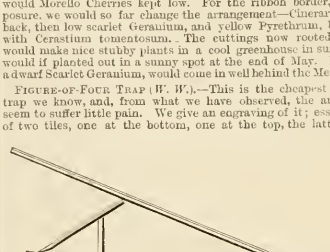
BOTTOM HEAT FROM HOT-WATER PIPES (*A. D.*).—By enclosing the pipes in a close chamber you will have bottom heat in the bed over them. The proposed openings are good, but the doors must fit closely. As the pipes are heated by gas we would propose the top of the chamber, otherwise the bottom of the bed, to be of zinc or galvanised iron, and without perforations. The supports across may be of wood or iron, and the closer they are, say 18 inches apart, the less will the iron give way. We would have the zinc vessel turned up at the edges for from 1 to 2 inches, so that a little water would stand at the bottom when required. A few pebbles or bits of charcoal might be placed along the bottom for the bottom of the pots to stand on, with a little moisture beneath them when deemed necessary. There is not the slightest danger, as you have been told, of the zinc melting. We would use the cocoanut refuse between, not below, the pots. The zinc may be nearer the pipes than 3 inches. Your success will much depend on having hand-lights, or moveable wooden boxes with glass tops, over the bed.

CROCUS STIGMA PROMINENT (*R. K. C.*).—The white Crocus flowers you enclosed to us do not differ from the usual type, only the stigmas are very prominent: their deep yellow or orange colour contrasts well with the pure white of the rest of the flower. You will find the stigmas are present in the coloured varieties as well, but are not so conspicuous. The specimens are perfect and very pretty.

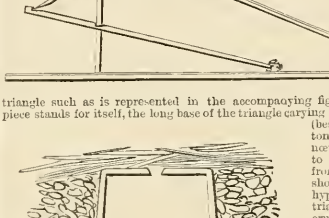
SEEDLING VIOLET (*A. Godward*).—It has no special merit.

FLOWERS FOR BORDERS (*A. A.*).—On your narrow north border Violets, Snowdrops, Crocuses, and Forget-me-nots would do admirably in spring, and Daisies and low herbaceous plants in summer. For fruit, Black Currants, Red Currants, and Gooseberries would succeed well against the wall, and so would Morello Cherries kept low. For the ribbon border, with a better exposure, we would so far change the arrangement—Cineraria maritima at the back, then low scarlet Geranium, and yellow Pyrethrum, blue Lobelia edged with Cerastium tomentosum. The cuttings now rooted of Alternanthera would make nice stubby plants in a cool greenhouse in summer, and so they would if planted out in a sunny spot at the end of May. Purple Verbena, or a dwarf Scarlet Geranium, would come in well behind the Mesembryanthemum.

FIGURE-OF-FOUR TRAP (*W. W.*).—This is the cheapest and most effective trap we know, and, from what we have observed, the animals killed by it seem to suffer little pain. We give an engraving of it; essentially it consists of two tiles, one at the bottom, one at the top, the latter supported by a



triangle such as is represented in the accompanying figure. The upright piece stands for itself, the long base of the triangle carrying the bait at one end (best clear of the bottom for delicate manœuvres) notched to fit to it, and notched in front to receive the short front piece, or hypothenuse, of the triangle bearing the crushing tile. The mouse nibbles at the bait, disturbs the hold of the front piece on the base, and down comes the whole. Another good trap is a flower-pot inverted in the soil over a saucer, as represented



in the accompanying figure, and slightly covered with leaves. Of course Peas or some other bait should be placed in the saucers.

FLOWER-BEDS (*Kittie*).—What we chiefly admire in your flower garden is the simplicity of the design and the great simplicity in the proposed planting. Thus, you have a rather long octagon in the centre, with the sides curved-in to leave eight points, eight circles round, the curve of the circle suiting the curve in the octagon, and then eight clumps round, which would be nearly semicircles, except that a curved line passes from the centre of the diameter to join the circumference, the sharp angle of each of these facing the sharp point of the octagon, a supposed line passing between these two points having a circle on each side. Then the proposed planting is equally simple. Several bands for the large centre, the eight circles to be filled with Calceolarias, edged with purple Verbena; and of the eight outside beds, four to be filled with scarlet Geraniums edged with Flower of the Day, and four with pink Geraniums, edged with Perilla pegged down. Here simplicity is so far departed from, and the edging of Perilla would come in between two beds with an edging of purple Verbena. If we had all the circles alike we would make all the outsides alike; but here, again, we fear that simplicity would be gained at the cost of sameness. We would rather take the key-note from the outside beds, and if we had not four distinct pairs we would at least have four beds of a sort in each ring. Without some such breaking-up, and if the different rounds of beds were planted alike, we do not see why as good an effect would not be produced by having one large bed, and the colours arranged in massive bands. But now to a few particulars. As the place is so windy, we would not use Coleus for the centre bed, but Iresine Lindeni, and one point in its favour is that it will stand a month or six weeks longer than the Coleus in ordinary autumns. The arrangement then would be, beginning at the centre, Centaurea, Iresine, Polemonium variegatum. Another arrangement is very good, only we would alter it so as to stand thus:—Centaurea, Iresine, Mrs. Pollock, blue Lobelia, with just a string of Cerastium tomentosum. Then, as to the circles, we would plant each alternate one, as you propose, with strong yellow Calceolaria, and edge with Purple King Verbena. The other alternate four might be Purple King and a low yellow Calceolaria, as Aurea floribunda. We would, however, prefer Imperial Dwarf Ageratum and Aurea floribunda Calceolaria. Then, for the outside beds, we would have four bright scarlet Geranium beds edged with a white variegated kind, as Bijou, and four alternate beds of Christine or Amy Hogg, edged with Flower of the Day. As you have Mangles' Variegated you might use it, but it requires a broader band than you can give it in these beds to make it effective.

HOTBED FOR CUTTINGS (*Idem*).—We prefer a bed of dung and leaves to dung alone, it is so much more lasting; and if a coating of leaves is kept at the surface, there is little danger of noxious steam.

PLANTING SEA-KALE (*Nemo*).—The best time to plant Sea-kale is at the end of March or beginning of April. The ground should be trenched 2 feet deep, or deeper if you have good soil, adding manure, leaf soil, and decayed vegetable matter liberally, mixing them well with the soil, and if the ground is heavy add a quantity of sand. Sea-kale likes rich, light, sandy

well-drained soil. Your one-year-old plants will be good for planting. If you intend to force on the ground, put in three plants in the form of a triangle, 8 inches from point to point, and 2 feet between each triangle of plants. The rows should be 15 inches from the sides of the bed, and this will admit of your putting in two rows 18 inches apart along your 4-feet bed. We should have preferred 2 feet as the distance between the rows. We presume the alleys are 2 feet apart. In planting, if the ground is heavy and wet, surround the root-stem up to the crown with sand. If the soil is dry water it, and in moist weather in May sprinkle the bed with salt, at the rate of 1 lb. per square yard. Water freely with liquid manure throughout the summer, stirring the ground frequently, and being careful not to injure the leaves. It will be fit to force next winter. If you intend taking up for forcing, plant in rows 15 inches apart, and the plants a foot apart in the rows.

ABUTILON VEXILLARIUM MARMORATUM GRAFTING (*A. B., Ireland*).—We have no doubt this plant will succeed better grafted on a hardier kind, but we know of none hardier than the species A. vexillarium, and on that we should graft now, placing the plant in gentle heat, and keeping it close until the union is complete. Whip-grafting will answer well.

PLANTS FOR WINDOW BOXES UNDER VERANDAH (*Mary*).—Being beneath the shade of the verandah we fear the plants in the boxes would not succeed very well. We should have for edging Alyssum variegatum and Lobelia speciosa, with a plant or two of Mignonette at the corners, and at the centre of the sides of the boxes, filling in the centre with a low-growing Geranium at each end, as Blackband, then Imperial Dwarf Ageratum, and Lady Cullum Tricolor Pelargonium in the centre, making both sides of the box alike. If you wish for anything more sweet, then have an edging of Mignonette, and fill the centre with Ten-week Stocks. The best time to plant Czar Violets is from now up to May, but we prefer moist weather at the end of April. Select good runners or offsets. For the arches in a warm situation we should have the following Roses—viz., Climbing Devoniensis, Gloire de Dijon, Tea-scented; Alfred Colomb, Glory of Waltham, Eugene Appert, Camille Bernardin, Adolphe Brongniart, and La France, Hybrid Perpetuals; Sir Joseph Paxton, Bourbon.

BOILER (*A Foreigner*).—We have no doubt that a No. 5 boiler of the firm you name would suit your purpose, but for five such large houses, 17 to 22 feet wide and 160 feet long, we should strongly advise two such boilers, set side by side, to be used separately or together, chiefly in the case of frost. The outlay would be a cheap insurance. We join you in having our doubts of large cast-metal boilers. For saddle-backs we would have the best welded iron, and for such houses we should like two boilers side by side, each 6 feet long, and at least 3½ feet in height.

GREENHOUSE VINERY ARRANGEMENTS (*J. N. Lauson*).—We presume that by the proposed direction of the flue, you mean to divide your house of 21 feet in length into two portions, so that the division next the furnace should always be warmer than the other. This you will secure by the proposed mode of taking the flue along the side, front, and up the other side of the first division, then returning it close to the division wall along the front, and round to the chimney in the second division. The only objection is, that if the flue is above ground, you will have to sink the flue twice at that division for the doorway, and once more at the entrance door in the second compartment, and these three sinkings will interfere with the free draught of the flue, unless your chimney is 20 feet in height. You would secure much the same object, but with less command of heat, by omitting the cross flues at the partition, and taking the flue right along the front of both houses; then you would have only one sinking beneath the pathway at the entrance doorway, and even that might be avoided by turning your flue on the south side of the doorway, and taking it to the chimney near the partition. We allude to this because, in general, the more dips there are in a flue the higher you must make your chimney; merely for a greenhouse vinery for keeping frost out, and in a house 21 feet by 12, we would avoid all such trouble by having a sunk flue—the top of the flue forming part of the floor or pathway. We presume, however, you mean a flue above ground. With regard to forming the flue, for such a place a small flue will be ample. Make a firm base, say with a layer of bricks, 14 inches wide, and plaster the surface with lime putty. Place two bricks on edge on each side, so as that the outsides will measure 12 inches across, leaving about 7½ inches inside for the flue. This will be ample for such a place for general purposes. These bricks should be well burned, be soaked previous to use, be set as straight as possible on the inside, and be united at the joints with fine lime putty, making the joints as small as possible. If you want a forcing heat, three bricks should be used on each side instead of two; for covering, 1-foot tiles about an inch thick will do. It is safer, however, to have some thin flat house tiles to lay across first, and plaster them all over, and on that place the top tiles. We would rather not do anything at all in the way of plastering the inside of the flue. You may use a little plaster for the sides outside, or a thickish limewash, which you can darken with a little lampblack. The holes you allude to for cleaning the flue should be at the different turns. You can easily have plates set in a frame from 6 to 9 inches square; build these in the inside of the flue, so that the plate shall run with the inside of the flue. You can fill-up outside with a tile and plaster, and remove these and open the plate when you wish to clean. This is a great improvement upon being forced to unsettle the flue. For such a house, a furnace 2 feet in length, 18 inches wide, and 18 inches deep, would be ample for coal fuel. If you depend on breeze or cinders, the width and length should be respectively 4 inches more, and 6 or 8 inches more, and the flue should be 3 or 4 inches deeper if you depend chiefly on wood. In either case as respects fuel, your furnace bars should be from 24 to 30 inches beneath the bottom of your flue; the greater the rise the greater the draught, and that is easily regulated by a close-fitting ash-pit door.

VINES FOR GREENHOUSE VINERY (*Idem*).—For such a house five Vines would be ample, and we would recommend for a rather cool house three Black Hamburghs, one Royal Muscadine, and one Buckland Sweetwater. We would place one Hamburgh and one Muscadine in the warmest compartment. For Muscadine you might substitute White Frontignan, and Black Muscat of Alexandria (Muscat Hamburgh) for one Black Hamburgh if you are fond of the Muscat flavour. This is a good time to plant. The border outside should not be less than 2 feet deep over some 6 or 8 inches of open rubble. Nothing is better than sweet fibrous loam, with about a tenth part of lime rubbish and some six bushels of crushed boiled bones, reserving other manure chiefly for surface-dressings. For these and other matters consult the "Vine Manual," which you can have from our office by post for 2s. 8d.

INSECTS (*J. R. G.*).—The insects sent are the Lepisma saccharina, commonly called Silver Ladies, found in old cupboards, where they eat crumbs, scraps of groceries, paste of wall paper, &c. The silvery scales are used by microscopists as test objects.—I. O. W.

NAMES OF PLANTS (*B. Godbold*).—To name "the box full of Ferns, &c.," would occupy the major part of a day. We cannot spare the time, and we have a notice printed that we request no one to send more than six specimens at a time. (*Hildenborough*).—The Cornelian Cherry, Cornus mas. (*C. G., Carlton*).—1, Adiantum hispidulum; 2, Pellæa adiantifolia; 3, Doodia candata; 4, Platyloma rotundifolia; 5, Adiantum diaphanum; 6, Pteris longifolia. (*R. Johnson*).—Senecio Petasites. (*M. A. M.*).—1, Convolvulus Cneorum; 2, Correa; 3, Saxifraga crassifolia; 4, Leptospermum virgatum; 5, Erica cerinthoides coronata; 6, Tasmania aromatica; only female flowers were borne on the shoot sent. (*W. H. M.*).—Apparently Rhododendron Windsori, as figured in *Bot. Mag., t.* 5008. (*M. D., Braintree*).—An Epacris; name next week.

POULTRY, BEE, AND PIGEON CHRONICLE.

FOWLS FOR PROFIT, AND AS A MEANS OF SUBSISTENCE.—No. 2.

SELECTION OF BREED WHEN CONFINED.—This plan is in itself a disadvantage. First, the fowls will require more food, and although as a set-off we obtain a greater quantity of manure, still this does not pay for the extra outlay in food. Secondly, the Hamburgh breed, which, as I have before stated, has no equal in its capabilities of laying, will not tolerate confinement. In this contingency I would advise the substitution of the Houdan fowl for the Black Hamburgh, as being the next best egg-producer. This breed, like the Black Hamburgh, never shows a disposition to sit. I may remark, in passing, that as it is imperative to have a constant and undiminished supply of eggs, those who intend to derive a subsistence from their poultry must be careful to place in their egg-producing department hens which are non-sitters.

The Brahma Pootra must still retain their place for supplying us with chickens; they will thrive in confinement almost as well as if at liberty. It must be borne in mind that poultry kept in confinement will require double the amount of attention of those which have a run.

INCUBATION.—Hens will show a disposition to incubate at almost any time if attention is paid to warmth and to their food, which should be slightly stimulating in the winter months. The Brahma chickens can be reared without difficulty in midwinter, and without exception each hen as she becomes broody should be allowed to sit. In cold weather she should not have more than nine eggs given to her, and in the spring and summer she may have from twelve to fifteen. The nest must be made of straw, never hay, and if the floor of the sitting-house is made of earth and small stones beaten well together, the nest may be made on the floor; but if it is flagged or bricked, a fresh-cut grass sod, the size of the sitting-box, must be placed on the floor to give a dampness to the eggs.

The henwife must attend to the sitting fowls at regular periods each day to give them food and water. They may all feed together, and may be allowed about a quarter of an hour's absence from the eggs; this time may be exceeded in the summer by a few minutes, but on no account in the winter months. If the weather is dry it is an excellent plan, and sometimes almost a necessary precaution, to take each hen, holding her gently by the wings, and with the other hand wet her breast feathers with cold water immediately before she returns to the eggs. This is better than wetting the eggs themselves with a small brush as some writers have recommended; in the latter case the eggs receive a cold moisture, whereas if the feathers of the hen are wet, the heat of her body imparts a gentle and most beneficial moisture to the egg, which is of the greatest benefit to the imprisoned chick. The henwife must remain in the sitting-house until the hen is safely on her own eggs again, as sometimes a quarrel will arise, and we have known two hens determined to share the same nest, to the great danger of the eggs.

The time of incubation is twenty-one days, and if at the end of ten-days sitting the eggs are examined by holding them before a lamp or candle in a room from which the light is excluded, those which are unfertile will be found to be quite transparent, whilst the fertile ones will be opaque, and the air-bag distinctly marked at the round end of the egg. This is an economical proceeding when two or more hens are set on the same day, as, should there be any unfertile eggs, it is sometimes possible to divide the fertile eggs between the two hens, and set the third hen again on a fresh sitting. We never disturb our hens when hatching-out, but food must be placed before them when this process is accomplished. Care must be taken to keep the chickens warm and dry for a few days, but after that the Brahma chicks will thrive with ordinary attention.

The Hamburgh chickens will require to be attended to a little longer, but if the weather is fine they will soon be independent also.

Nothing is so essential to the well-being of chickens as warmth, cleanliness, and freedom from damp. Each sitting-house must be provided with a dustheap, composed of fine ashes, as the hens are often troubled with vermin, and their feathers should be dusted with sulphur, both as a preventive and a cure. The neglect of this simple precaution often causes the hen great annoyance, neither is it to be expected that she can sit her eggs well when restless and disturbed.

Should a hen not show a disposition to sit when required to do so, she must be placed in her nest with a few eggs, and kept very warm; her food must consist of buckwheat, hempseed, a little raw chopped liver, and Indian corn. She must also be kept dark, and she will probably soon manifest a desire to sit.—VINCENT FRASER.

POULTRY EXPERIENCE PURCHASED.—No. 4.

"DON'T put them in the pens," I said, "put them back into the hampers, and let my people run back home with them; I won't allow them to disgrace your show." "Nay, Madam," was the reply, "there is nothing amiss with your Brahma chickens, except that they are rather dirty." "Pray allow them to remain," said one of the managers of the poultry show held annually in our little country town," and remain they did, with what success I will tell you; but "your special correspondent" walked her short distance homeward certainly a sadder if not a wiser woman. I remembered eight months back how cheerfully I had parted with a piece of gold large enough to have satisfied the longing of my "bairns" for a donkey, yet I only received in exchange a polite acknowledgment and thirteen eggs. How skilfully they were packed for their long journey, to be sure; tissue paper, hay, soft wool, and softer moss, were all enlisted to insure their safety. They were at once entrusted to the motherly attentions of our most intelligent hen, and I need not tell how horrified I was to find four broken the next morning. Then I had to wait that interminable three weeks before I could count four, five—yes, six little grey chicks that must be fed on eggs, rice pudding, and groats, and carefully tended till they reached cockerel's and pullet's estate; also to exterminate that objectionable crooked comb and vulture hock, that undesirable brown or yellow tinge, and various other ills that Brahma flesh is heir to. When you have waded through all this "poultry experience," to discover at a glance that lots of people can get better birds than yours, is very hard.

At noon we went to the show, I to study "points," and the "bairns" to see how mamma's big "Charley" behaved himself in company and a cage (I think I have previously mentioned the sad fact of the head of the family being a heretic and an infidel where Dark Brahmas were concerned).

"Oh, wad some power the giftie gie us."

I quoted to a friend, "to know how those wonderful men breed such wonderful birds," as brimming over with admiration I stood among the prize pens with a keen sense of enjoyment none but a true lover of the species could either pardon or comprehend. Somebody says, "Show me your amusements, and I will tell you what you are." For my part I confess to perfect happiness among my feathered pets, and I am sure the affection is mutual; let a stranger walk through the yard, they run away in all directions. If I go among them they keep so close, I have to push them on one side with my foot. "Would you be surprised to hear they have highly commended your pens? and had there been prizes, yours would certainly have been first." I grasped my friend's hand with a fervour that cost me 4*s.* 6*d.* on the spot, for my glove became a total wreck. If I could only have invited those nice men, judge, committee, and stewards to dinner, and let them toast my pets in Veuve Clicquot and '34 port! I promised myself, however, that I would relieve my feelings by telling "our Journal" all about it, for I felt certain that you would be pleased to hear I had been at last highly commended, and you will no doubt share my joy when I take the Crystal Palace cup.

I have always closed my letters with a moral, and now do so from habit, "Blessed are they who expect nothing at a poultry show, but more blessed are they that get what they expect."—J. K. L.

DOVER AND CINQUE PORTS POULTRY AND PIGEON SHOW.—We are informed that his Royal Highness Prince Arthur, Earl Granville, Lord Warden, and the County and Borough Members, have become patrons. The guarantee fund list is now closed, and subscriptions are solicited towards the funds.

A VISIT TO MR. R. FULTON'S PIGEONS, NEW CROSS, DEPTFORD.

MR. FULTON, whose acquaintance I made some years since at Glasgow, and renewed it at various shows, is well known as one of the most successful exhibitors and best Pigeon-fanciers in Britain. His practical knowledge is very great, no man living knows a Pigeon better than Robert Fulton. I knew also that he had a large collection of high-class Pigeons. All these were sufficient reasons to make me accept his invitation to inspect his birds. But there was another and further reason. Those upper-class fanciers whom I know, and who know him, are accustomed to say, "Fulton's an honest man, and one whose word we can rely upon; if he sells you a prize bird, and it wo'n't breed, he tells you so. Then he not only asks a good price for a good bird, which, of course, he is quite right in doing, but he will give a good price for a good bird." These latter reasons were those which specially induced me to go to Deptford.

Deptford of ship-building fame, thought I. Why, John Evelyn, the author of "Sylva, or a Discourse on Forest Trees," lived there at his seat, Sayes Court, which he, unfortunately for himself, let to Peter the Great, when he came to Deptford to learn ship-building. Of Sayes Court, says chatty Mr. Pepys, "We walked in Mr. Evelyn's garden, and a lovely noble ground he hath indeed. And among other rarities, a hive of bees, so as being hived in glass, you may see the bees making their honey and combs mighty pleasantly." Unfortunately, the Czar had no taste for gardening or neatness, and trampled on good Mr. Evelyn's flowers, destroyed his choice shrubs, and used to amuse himself (the savage!) by being wheeled in a wheelbarrow through a neat-clipped hedge which Mr. Evelyn had raised with much care and cost. No wonder Mr. Evelyn's old servant said, "The Russians were right nasty."

I have talked of trees, flowers, and gardens, so giving the readers of the beginning of "our Journal" a turn; and of bees, giving the readers of the tail end a turn; of Pigeons presently. Perhaps these good gardening and bee people will read this, and get improved—that is, learn to love and keep fancy Pigeons.

But Mr. Fulton has recently left Deptford, and lives at New Cross. Deptford I knew well enough on the map—the Deptford of Dibden's song, "Wapping Old Stairs," in which he tells us—

"Of Susan from Deptford, and likewise of Sal,"

and of the faithful Molly who to her sailor husband (of the future) says—

"Still your trousers I'll wash, and your grog I will make."

Deptford I knew, then, very well; it lies on the Thames and joins Greenwich. But "Where's New Cross?" said I to a hardened Londoner, who actually walks by St. Paul's and the Monument, and does not look at either, and knows all the short cuts of the very city itself. "Where's New Cross?" said I. "New Cross is one of the first stations from London Bridge, or, to save your legs, take a ticket from Cannon Street, cost you a few pence, trains every ten minutes. There, go, and meet me at Lake's, Gracechurch Street, at lunch at one o'clock sharp, not a minute after. There—good morning." My informant having hurriedly jerked out these directions, was in a few moments one of the crowd of men moving eastward from the Mansion House Station. How quick these Londoners are! I wonder they can find time to breathe. Well, I prefer country ways.

Sure enough, I soon get to New Cross; it is just in the parish of Deptford, and just, and only just, in Kent. New enough it is; roads—not streets yet—roads worn this horrid wet winter into ruts as deep as in Wiltshire lanes. Planks are along the future footways, on which I trip carefully to avoid falling into the mud beside me, passing by masons chipping at the stone balustrades of new houses. New Cross! I see it all exactly—a new creation to meet the wants of the middle-class London workers, who spend the day in the city, but prefer sleeping in better air. Here are homes by hundreds of city clerks who have married on small means, and have set up here a neat, new, humble home. There's the baby at the window, soon to be perambulated by the little maid. There's the pretty young wife and mother, who will look out of the window

early on Saturday "for somebody," who has a holiday then. So I do not wonder, considering all things, that the houses greatly resemble each other in the many new streets of New Cross. "Can you tell me where Union Crescent, Brockley Road, is?" said I to one of the many masons, who, pausing in his chipping, answered, "Brockley Road I know, but I never heard of Union Terrace. Brockley Road—keep on past two turnings, then first to the right, and third to the left down the valley," &c. "Why, it must be miles," gasped I. "Oh! no; only ten minutes' walk." Well, I do reach Brockley Road, which seemed a comparatively old part of New Cross, for the road is a street clean and firm, a pavement to walk on, gas lamps, tidy shops, and the same, only six months older, neat houses, with neat blinds, with baby at the windows, and perambulators in the little gardens in front. "Where's Union Terrace?" asked I of a policeman. N.B.—Always ask a policeman if you don't see a postman. "Don't know, sir," said the gentleman in blue; "but, then, I'm almost a stranger here; but there's Paul's Terrace." I then asked a little maid washing the steps at a house in Paul's Terrace the same question. "Don't know, sir." Then I asked a jobbing gardener. "Don't exactly know, sir, but I think it's not far off." N.B.—He was making a new garden in front of a house born an hour before, so very new it seemed. Oh! how new New Cross is! It is spick-and-span new; it is bran new. I daresay it was all green hill the year before last. Names are not on the houses yet, save at Paul's Terrace. I was now getting hopeless, and meditated returning to London, and writing an article entitled "A Fruitless Journey to New Cross," when close by Paul's Terrace, close to that stupid servant girl's pail and mop, hard by that stupid gardener, and that foolish-faced policeman looking on, I peeped through a gate and saw the legs of a White Pouter in a pigeonry very new, indeed, at the bottom of a new garden, behind a new house. The house had no name on it (improve this, R. Fulton), no number on it, no "Union Terrace" on the end of the row. Well, I mounted the steps of that nameless, numberless house—a nice, clean, pretty house, and nice fresh air to be enjoyed on the top of the steps. If I were but a single curate I should wish to lodge there. Robert Fulton did live there, said a tidy little maid. She was right, for in the room are pictures of Pigeons, too accurate to be in any but the house of a good fancier. All right at last, thought I, and here came in Robert Fulton.

To the Pigeons, for time presses. First, I am shown, in passing, a zinc hopper of Mr. Fulton's invention, the neatest and best made for supplying the birds with food, and keeping it from all impurity, that I ever saw. With the hopper was also a specimen fountain, made of the same material, and of like excellence. Then I pass a round pond, where fancy Ducks are to be when Mr. Fulton gets settled. Straight before me, at the bottom of the garden, in the bright sunlight (for, strange to say, it was a fine day—a treat, indeed, after two months' rain), stand the long row of Pigeon pens. They are built—sides, back, and ends, as well as the roof—of corrugated galvanised iron. A good plan this, for rats cannot get through iron, and in case of removal they could be easily transferred to another place. Iron also puzzles thieves. The row of pens are divided into six compartments, each compartment being 11 feet square. A large window, heavily barred for fear, doubtless, of improper Pigeon-fanciers, is in the front of each pen. The window shutter removed, out came the birds into their place of exercise, this being exactly the same size as the pen within. It is well supplied with resting-boards and perches, on which the Pigeons can enjoy themselves, and on the floor in each a bath.

Entering, I come into the first division to the left containing the Pouters, some of which have done wonders at various shows. Mr. Fulton is at this time strong in all the varieties except Black Pieds. Some are wonders for shape and length. I measured a Blue Pied cock; 20½ inches good in length, and 7¼ in limb. Such lengths are often talked about, and people imagine they possess such birds, but they usually fail when the 2-feet rule comes out, and two persons measure the bird impartially. I measured Mealy birds and found them the same. Before me stood White Pouters of extreme elegance of form, and Yellow birds of wonderful soundness of colour. Indeed, such a number of such goodness was a rare treat to see. Pen No. 2 contained the choicest Carriers, some of them remarkable in head and contour. There were Blacks, Duns, and Blues. Pen No. 3 contained more Carriers. Nos. 4 and 5 were full of various classes. Mr. Fulton is very strong in Jacobins, some having their hoods flat to their heads. He had White Jacobins with pearl eyes, Barbs of various colours, Turbits, Owls, Fans, &c. Lastly came pen No. 6, full of Short-faced Tumblers; Almonds of various shades, the dark, the rich, the lighter. Some wonderful in colour, others in head and beak. Two (hen birds both, unfortunately) were Golden Duns. Then there were Short-faced Balds and Beards. This pen was to me particularly pleasing. The day had become warm as well as sunny, and as these dainty-shaped, sprightly little birds flew to the various alighting-boards in the outer aviary, and as their many-coloured plumage and bright hackles glittered in the sun, they formed a charming sight to one who has an eye for a high-class Tumbler. Their flights and tails were, too, remarkably clean; and as no feeders or other coarse birds were with them, there was nothing to take off their beauty.

Such is Mr. Fulton's pigeonry and its inhabitants, and may both he and they prosper in their new abode. Truly he has high-class birds. For my own part I could have spent many hours in those pens. The buildings themselves are well arranged. In each pen are the aforenamed hoppers and fountains. Mr. Fulton is giving up those rickety Birmingham triangles, neither good for foot nor wings, and is adopting Mr. Noyé's roosts, as described and pictured in vol. xviii., page 399, of this Journal (June 2nd, 1870), with this improvement, instead of round perches, flat pieces of deal 2 inches or so wide. I have done the same, and find the birds prefer them. I will also add that the slanting board should be a foot wide, to secure the dung from dropping below. Mr. Fulton has abundance of sawdust on the floors, which certainly gives a clean appearance. In the outer aviaries are the baths, flat zinc pans, 2 or 3 inches deep, and with a large margin; indeed they look like a flat pan set in a larger pan, the latter catching all the splash, and saving the floor from damp, and the birds' wings and tails from becoming draggled and dirty.

A peep at some Pigeon portraits in-doors, and a talk about Glasgow fanciers, and then a hasty good-bye, for my time was up.

I was pleased with all I saw at New Cross, and I am glad that the Pigeon-fancy has so advanced as to make it worth while for Mr. Fulton to get together a grand lot of high-class Pigeons of all the varieties; so that the better fanciers know where to put their hands upon such birds as from time to time they may require.—Wiltshire Rector.

BLACK HAMBURGHS.

I have often wondered why, except at some few of our leading shows, this beautiful variety is not allotted a separate class, but has to be shown either in the Any other variety or the Selling class. I should like to ask the committees of shows the question, and receive a answer, why the variety is thus treated.

They are one of the handsomest and best varieties of fowls we have. They are lovely in plumage; in their egg-producing qualities they equal any other breed; they are small eaters; they do not figure badly on the table; and if they are assigned a separate class at a show they seldom fail to appear in sufficient numbers to justify the pecuniary outlay. If any individual should say that they are not shown in sufficient numbers to warrant committees in giving them a separate class, I would just refer him to Wolverhampton, where a £3 3s. first prize brought out the very respectable entry of nineteen pens; whereas in neither of the other classes of Hamburghs did they surpass, and only in one instance—viz., Golden-pencilled, did they equal this number. Some may say that the reason of this lies in the fact that instead of a £3 3s. first prize there was only £2 for any of the other varieties; but still my opinion holds good, and shows that if they receive from committees that encouragement to which they are justly entitled, they will not fail to make satisfactory returns.

I cannot understand why some classes should be allotted £3, £2, and £1, and others only £2, £1 and 10s. Should not all be equally treated? as in most instances the entry fees are the same for one as the other.—Thomas Bush.

TRIMMING BIRDS FOR EXHIBITION.

Right glad was I to see the remarks you made in last week's Journal on trimming, and I trust that the committee of every future show will adopt the clause you suggest.

I have been very fond of poultry from my boyhood (the almond tree has begun to blossom now), and have somehow drifted into the "Fancy" a little of late, and have also indulged in the luxury of exhibiting a few pens with a fair amount of success. But really when I read so much about paint, pins, needles, scissors, glue, &c., in connection with shows, it makes me feel

there is something wrong going on, and the question arises, Ought I to have anything to do with it? I know more than one besides myself who has similar feelings on the subject, and will cease to exhibit altogether if such dishonest jobbery continues. Would it be possible to form a sort of confederation of exhibitors pledging themselves not to support any show unless a clause similar to that which you suggest be inserted in the entry form? At any rate it is clear some stringent measures must be taken, or honest exhibitors will give up in disgust, however much they may regret doing so.—CHELTENHAM.

COLCHESTER POULTRY SHOW.

THIS Show was held on the 21st and 22nd inst. The poultry and Rabbits were exhibited in the Corn Exchange, the Pigeons and Cage birds in the Public Hall. Both buildings are light, airy, and well adapted for showing off birds to the best advantage. There were nine silver cups distributed over the different classes, and the money prizes were equally liberal, so that the Committee deserved a numerous entry, and we were pleased to find on entering the Exhibition they had not been disappointed, as there were 536 entries. The whole of the arrangements were good and admirably carried out, the birds well cared for, but we do object, and that very strongly, to the pens being strewed with sawdust. It may keep the birds drier and cleaner than sand, but they are sure to eat some, and when the soft food is given it gets mixed with the sawdust, which is then swallowed. When it gets into the crop the wood swells, causes indigestion, and often lays the foundation of many other diseases. Sawdust is very injurious, whilst sand, or the small stones found amongst it, are absolutely necessary for the birds' health, and these small grinders are even more than ever required when birds are confined in a pen for several days with nothing to assist their digestive organs. We therefore consider it necessary that the bottoms of the pens should always be strewed with sand or fine gravel.

The Coloured *Dorkings* were good. The cup pen looked sadly out of condition. We hardly liked the second-prize pen so well as a highly commended pen. Whites mustered very well, and most of them were above the average in quality. The cup for *Cochins* went to a splendid pair of Buffs; Partridge were first and third in the Any Variety class; Whites were second. The Dark *Brahmas* were very numerous, and most of the birds good; many, however, showing the evil effects of continuous exhibition. The Lights were a very inferior lot. *Spanish* numbered thirteen pens, and the quality throughout was better than we have seen for some time, the cup being won with a capital pair, of which the cock was very long in the lobe. This pen was closely pressed by a pair of old birds, which stood second. *Game* were very good; Blacks and Browns competed together, an uncommonly nice pair of Brown Reds winning, a Black Red being second. The Duckwings won the cup; only the third prize was awarded in the Variety class, some of the birds being gouty. *Hamburghs* were numerous and above the usual average for a show in the South. The awards for Black and Brown Reds we did not like; we thought the second-prize pair far more after the stamp and style of a Game bird than their more fortunate rivals. The cup went to a very pretty Duckwing cock, but the hen which was with him was very inferior, and he is deserving of a more handsome mate. In the Bantam variety class some beautifully Laced birds were first. *French* were good, and the *Polands* very few. Malays were first in the Any other variety class, Sultans second, and a good pair of Cuckoo Dorkings third.

Rouen *Ducks* were a good entry, but of the Aylesbury there were only two entries, and one of these was absent. How is it we find at almost every show this beautiful and valuable breed gradually getting less in size and fewer in numbers? In the Selling classes the entries were numerous, consisting of the usual miscellaneous mixture of good, bad, and indifferent which we always find in this class.

For *Pigeons* a cup was given to the winner of the greatest number of prizes; but why such cups are ever given we are at a loss to conceive, unless it is to induce some people to borrow birds of others. Possibly it may induce one or two exhibitors to send a few extra entries, but they hunt up all their friends for the loan of birds, and thus prevent many others from sending. We know of one or two instances on this occasion. Amongst the Pigeons several pens were disqualified. We should like to see a rule made by the committee of every show, that where any exhibitor was found to have either trimmed or tampered with birds he should be prevented from taking any prizes. If this had been the case at Colchester a winner of one of the chief prizes would never have had it. Carriers were good. Mr. Horner had a pen in each class disqualified. Of the ten pens of Pouter cocks entered eight were noticed by the Judges, showing the general superiority of the birds. Tumblers were very neat and pretty, Mr. Horner again disqualified for trimming. Jacobins proved a good class, also the Turbits. Barbs, with the exception of the winning pens, were hardly up to the average. In Nuns the first and second prizes were withheld, the Judge stating the majority of the birds were grossly trimmed. The working Antwerps were, as usual, very numerous, and most of the birds of superior quality.

The *Rabbits* were not very large in numbers, but some of the specimens were of unusual length of ear.

The attendance on the day we were present was very large, many of the neighbouring gentry being present and purchasing very freely.

DORKINGS (Coloured).—1 and Cup, L. Pattoo, Hillmore, Tanaton. 2, O. E. Cresswell, Early Wood, Bagshot. 3, L. Wren, Lowestoft. *hc*, G. W. Greenhill; F. Parfett, Great Baddow; W. S. Marah, Deal.

DORKINGS (White).—1, O. E. Cresswell. 2 and 3, Rev. F. Tearle, Gazeley Vicarage, Newmarket.

COCHINS (Cinnamon and Buff).—1 and Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, G. Stickings. 3, A. A. Seahora, Hadleigh.

COCHINS (Any other variety).—1 and 3, Horace Lingwood, Crecting, Needham Market (Partridge). 2, R. S. S. Woodgate, Pembury, Tunbridge Wells (White).

BRAHMAS (Dark).—1 and Cup, T. F. Ansdell, Cowley Mount, St. Helen's. 2, Horace Lingwood. 3, Rev. J. G. B. Knight. *hc*, Dr. Holmes, Whitecotes, Chesterfield; B. Parrott, Heabury, Bristol; W. J. E. Shalford, Maidstone (2); H. Dowsett, Pleshey, Chelmsford: Lady Gwydyr. *c*, J. Drake, Ongar.

BRAHMAS (Light).—1 and 3, H. Dowsett. 2, P. Hance. *hc*, Mrs. T. Turner, Avon, Ringwood.

SPANISH.—1 and Cup, Nichols Bros., Camberwell. 2, Mrs. Tonkin, Bristol. 3, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. *hc*, W. E. J. Shalford; Hon. Miss D. Pennant (3), A. W. Woodhouse.

GAME (Black-breasted and other Reds).—1, W. Rayner, Ipswich. 2, S. Matthews, Stowmarket (2). 3, E. Winwood. *hc*, J. Fletcher, Stoneclough; W. Foster, Deal; F. Harding, Chingford; B. Boyes, Beverley; S. Matthews.

GAME (Duckwing and other Greys and Blues).—1 and Cup, S. Matthews. 2, W. Foster. 3, E. Winwood.

GAME (Any other variety).—1 and 2, Withheld. 3, J. H. Salter, Tolleshunt D'Arcy (Pile).

HAMBURGHS (Gold and Silver-spangled).—1 and Cup, Ashton & Booth. 2, L. Wren, Lowestoft. 3, W. Groom, Ipswich. *hc*, W. K. Tickner, Ipswich. *c*, T. Love, Kingsthorpe, Northampton; R. & H. Ashton, Mottram.

HAMBURGHS (Gold and Silver-pencilled).—1, J. Webster, Helbrook, Lancashire. 2, R. E. Parker. 3, W. K. Tickner. *c*, C. Blodworth, Cheltenham.

GAME BANTAMS (Black and other Reds).—1, W. B. Jeffries, Ipswich. 2 and 3 W. Adams. *hc*, W. S. Marsh; G. F. Ward, Wrexbury.

GAME BANTAMS (Any other variety).—1, Cup, and 3, Rev. F. Cooper, Ampney (Duckwing). 2, G. Smith, Staveley (Pile). *hc*, W. Adams (Duckwing); F. Fielder (Duckwing). *c*, E. Branford (Duckwing).

BANTAMS (Any variety except Game).—1 and *c*, M. Leno, Markyate Street, Dunstable. 2, Rev. F. Tearle, Gazeley Vicarage, Newmarket. 3, R. & H. Ashton. *hc*, F. E. Thirtle, Lowestoft; J. Bloodworth, Cheltenham.

FRENCH.—1, C. H. Smith, Radcliffe-on-Trent. 2 and 3, W. Dring, Faversham. *hc*, W. Burrows, Diss; G. Chilton, Littleton, Guildford; Mrs. J. Cross, Appleby Vicarage, Brigg. *c*, W. Tippler.

POLANDS.—1, 2, and 3, W. K. Patrick, West Winch, Lynn.

ANY OTHER VARIETY.—1, Rev. G. A. Brooke, Shrawardine (Malays). 2, W. H. Tomlinson, Newark-on-Trent (Sultans). 3, Rev. F. Tearle (Cuckoo Dorkings). *hc*, R. S. S. Woodgate (Silkies). *c*, Mrs. F. Parlett (Cuckoo Dorking); J. P. Fawcett (Black Hamburghs); Lady Gwydyr (Silkies).

DUCKS (Rouen).—1, F. Parlett. 2, H. Dowsett. 3, J. Drake. *hc*, R. W. Richardson, Reverley. *c*, F. Parlett; H. Dowsett.

DUCKS (Aylesbury).—1, G. W. Greenhill, Ashford.

DUCKS (Any other variety).—1 and 3, M. Leno (Mandarin and Carolina). 2, H. B. Smith. *c*, R. S. S. Woodgate (Labrador).

SELLING CLASS.—*Cock.*—1, W. N. Cater, Colchester (Poland). 2, W. Rayner (Brown Red Game). 3, J. Hare, Shotley, Ipswich (Duckwing). *c*, C. Denton, Lowestoft (Brahma); W. E. J. Shalford, Addington Park, Maidstone (Houdan); M. Leno (Brahma).

SELLING CLASS.—*Hens.*—1, Lady Gwydyr. 2, H. Grias Ipswich (Spanish) 3, R. W. Richardson (Dorking). *hc*, E. Branford (Black Red Game). *c*, H. N. Crozier (Black Red); F. A. Cole (Spanish); H. Dowsett (Brahmas); Nichols Bros. (Spanish).

PIGEONS.

CARRIERS.—*Cock.*—1, E. Horner, Harewood. 2, H. Yardley, Birmingham. 3, L. Wren. *hc*, T. King; J. Ford, London. *c*, W. N. Cater.

CARRIERS.—*Hens.*—1, E. Horner. 2, J. Ford. 3, T. King. *c*, S. Holroyd, Oldham; W. Crook. *Disqualified*, E. Horner (beak wattle glued).

POUTERS.—*Cock.*—1, J. Ford. 2, Mrs. Ladd, Calne. 3, E. Horner. *hc*, R. W. Richardson. *c*, W. Crook, Swansea (2); H. G. Holloway, jun., Stroud; E. Horner.

POUTERS.—*Hens.*—1, J. Ford. 2 and *hc*, Mrs. Ladd. 3, E. Horner. *c*, W. Crook.

TUMBLERS (Almond).—1 and 3, J. F. rd. 2, E. Horner.

TUMBLERS (Any other variety, Short-faced).—1 and 2, J. Ford. 3, J. W. Edge, Birmingham. *Trimmed*, E. Horner.

OWLS.—1, E. Horner. 2, J. Ford. 3, R. Richardson. *Disqualified*, J. W. Edge.

FANTAILS.—1, E. Horner. 2 and *hc*, H. Yardley. 3, J. W. Edge. *c*, Mrs. Ladd; J. F. Lovesmark.

JACOBINS.—1, J. Ford. 2, E. Horner. 3, G. South, New Bond St., London. *c*, J. W. Edge; E. Horner.

TURBITS.—1, J. Ford. 2, J. W. Edge. 3, G. South. *hc*, R. W. Richardson; O. E. Cresswell; H. Yardley.

BARBS.—1, J. Ford. 2, S. Holroyd. 3, H. Yardley. *c*, E. Horner.

NUNS.—1 and 2, Withheld. 3, R. W. Richardson.

TRUMPETERS.—1 and 2, E. Horner. 3, C. Norman, Ipswich.

DRAGOONS.—1 and 3, G. South. 2, S. Holroyd. *hc*, J. W. Edge; H. Yardley. *c*, J. Ford.

MAGPIES.—1 and 2, E. Horner. 3, R. W. Richardson. *hc*, H. Yardley.

ANY OTHER VARIETY.—1, T. D. Green (Blue Runts). 2, H. Yardley. 3, E. Horner (Swallows). *hc*, Rev. G. A. Brooke (Swallows); T. D. Green (Silver Runts); G. South (Persian); H. Yardley; J. T. Cater (Ice). *c*, W. Crook (Ice); S. A. Wyllie, East Mousley (Ice).

ANTWERPS (Working).—1, J. T. Galey, Colchester. 2, P. H. P. Price, Brecon. 3, E. Horner. *hc*, P. H. P. Price; F. Harwood, jun., Colchester; F. Mantherp. *c*, P. H. P. Price; T. King; J. T. Cater, Colchester.

SELLING CLASS.—1, H. Yardley. 2, 3, *hc*, and *c*, J. T. Cater (Black Carriers, Ice, Red Pouters, Red Mottled Tumblers, Yellow, White Fantails, Almond, and Starlings).

CAGE BIRDS.

NORWICH Yellow or Buff).—1 and 2, J. Mortimer, West Smithfield, London. *vhc*, T. Fenn, Ipswich; J. Mortimer (2).

NORWICH (Marked or Variegated Yellow or Buff).—1, R. Poole, Maldon. 2, *vhc*, and *c*, J. Mortimer. *hc*, T. Fenn.

BELGIAN (Clear or Variegated Yellow or Buff).—1 and *hc*, J. Hayes, Sutton-in-Ashfield. 2, J. N. Harrison, Belper. *vhc*, J. N. Harrison; T. Fenn.

LIZARD (Gold and Silver-spangled).—1 and 2, J. N. Harrison. *vhc*, *hc*, and *c*, T. Fenn.

MULE (Any variety).—1 and *hc*, R. Hawman, Middlesborough (Goldfinch and Canary). 2, Extra 2, *vhc*, and *c*, T. Fenn.

ANY OTHER VARIETY.—1 and 2, T. Fenn (Cinnamon). Equal 2, J. Mortimer (Crested Norwich). *vhc*, J. N. Harrison; A. Palmer (Buff Crested); J. Mortimer (Crested Norwich). *hc*, R. Poole (Jonque Cinnamon); J. N. Harrison; T. Fenn. *c*, J. Mortimer (Crested Norwich).

GOLDFINCH, BULLFINCH, OR LINNET.—1 and 2, J. N. Harrison (Goldfinch). SELLING CLASS.—1 and *hc*, T. Fenn. 2 and *c*, J. Mortimer. *vhc*, T. Fenn (9). FOREIGN BIRDS (Any variety).—1, E. Holmes, Colchester (King Parrot). 2, Mrs. Webb, Colchester (Australian Parroguets). *vhc*, O. Bawtree, Colchester.

RABBITS.

LOP-EARED (Any variety).—1, C. King, St. John's Wood. 2, H. Cawood, Thorne. 3, A. H. Easten, Hull. *hc*, H. Thurlow, Burnham Market; C. King. *c*, E. Robbiasn, Kettering; J. C. Garrington, West Bromwich; G. Slace, Hastings.

HIMALAYAN.—1, A. L. Peace, Doncaster. 2, W. Donkin, Driffield. 3, H. G. Hudson, Hull.

ANY OTHER VARIETY.—1, A. H. Easten (White Angora). 2, E. H. Gilbert, Rugby. 3, A. Wright, jun., Colchester (Angora). *c*, Master H. E. Manthorp, Colchester (Angora); C. King (Angora); W. H. Tomlinson, Newark (Angora).

SELLING CLASS.—1 and 3, J. Farrow, Romford (Lop-eared). 2, J. T. Cater (Angora). *hc*, C. King (Tortoiseshell); A. H. Easten (Lop eared, Spanish); F. Harwood, jun. (Tortoiseshell).

JUDGES.—*Pigeons and Rabbits:* Mr. W. B. Tegetmeier. *Cage Birds:* Mr. G. Moore, Park Street, Northampton. *Poultry:* Mr. E. Hewitt, Sparkbrook, Birmingham.

CARRIER PIGEONS—CONSTRUCTING A BREEDING LOFT.

I HAVE been several times requested to give my ideas with respect to the construction of a loft for breeding Carriers, and thinking they may be of service to your readers I forward them to you.

I believe non-success in breeding this noble variety of Pigeon is chiefly owing to several pairs being crowded together in a small space, the result being a great amount of damage to the adult birds by fighting—so frequently the cause of wing disease and canker—and the loss of numbers of eggs and young ones in the nest. Carriers are a prolific variety, and a good proportion of young birds may easily be reared. By adopting the plan I recommend, these misfortunes are entirely avoided, and, so far as I have myself practised it, I found it answer remarkably well.

The building may be erected at a very moderate cost. The erection is like an ordinary shed. A wall 9 or 10 feet high, with a south aspect, will answer for the back. The front of the shed should be 6 feet high, which allows of a 3-feet fall in the roof to carry off wet. The roof should be boarded flat with 1-inch deals (I mean of course with the above-mentioned inclination), felted, well tarred, and spouted. The ends of the shed, and the back, if there is no wall to work on, should be double-boarded, leaving about 3 inches between the inner and outer boards, and the vacancy well filled with sawdust. Such walls retain a more even temperature than brick or stone, being neither so cold in winter nor so hot in summer, and are, besides, less expensive. In width the loft may be 12 or 14 feet; the front boarded-up from the ground 3 feet high, the remainder to the roof wire netting. Inside under the roof shutters should hang on hinges, to fall down and cover the wire front during the cold nights, and at other times when necessary. When out of use they swing up and lie flat to the roof, where they are fastened, and are then quite out of the way.

At the back of the loft (there is no limit to the length except in the number of breeding pens required), is a platform 4 feet in width, half way between the floor and roof, to form the bottom of the pens. Thin iron rods, 1 inch apart, running from the platform up to the roof, form the front of the pens, each pen being 4 or 5 feet long (the longer the better) furnished with door, nest-box, &c. The loft at the length of every three pens should be divided, so that the occupants of every three pens may have their flight, bath, &c., in the area in front in turns. Thus the pairs are always separate, and breed undisturbed. Under these three breeding pens, which constitute one section of the loft, the front from the outer edge of the platform to the ground should be wired, with a door, and fitted with perches; so that will form a most convenient place to draft the young ones into as they are fit to leave their parents. As there will be two or three such compartments in a loft of any pretensions, the sexes can be separated when desired. In this arrangement the birds are always under command, and easily caught when required.

The finish of such a building is, of course, a matter of taste and outlay. The exterior may be planed and painted, or only in the rough and tarred, the inside in either case being well limewashed annually, at the commencement and close of the breeding season. —W. MASSEY, *Spalding*.

THE DRAGOON PIGEON.

MR. MINSON does not like the stout beak I advocate, nor yet the spinate, but the happy medium. I think, however, from his letter that he does not exactly understand my meaning. I do not wish it to be thought that I am in favour of the heavy coarse-wattled bird.

My idea of a Dragoon is as follows:—The bill should be strong from the base, and slightly curved at the end; the eye wattle neat, circular, and not pinched; a light-coloured beak inadmissable; the wattle on the beak should be fine and lie close. The eye should be full and bright. The bird should be very hard-feathered, with shoulders well out in front and have a good broad chest; but, however good in other points, I should pass them in the show pen if the carriage were not good. I think the Game cock is the best model in point of carriage for a Dragoon with its proud defiant look, with head erect, and ever on the watch. The blue rump is now universally acknowledged as being correct. The very broad bars I dislike; they should be jet black, well defined, and not exhibit the slightest approach to a sooty character, which so many Blues have at the edge of the bars. The birds should be of a good sound colour; light thighs I consider a great defect.

I hope some large breeders will take the matter up, and give us their experience, to see if we cannot set up a standard of excellence to aim at.—F. GRAHAM.

P.S.—As if still further to increase the difficulty, I have received word from a correspondent of mine, since writing the above, that at a local show held last week the first prize was awarded to a pair of Blue Dragoons with light rump and *white beaks*, and by an eminent Judge too.—F. G.

CRYSTAL PALACE BIRD SHOW.

(*Concluded from page* 184.)

AMONG Silver Lizards, No. 467, Mr. T. W. Fairbrass, was grand. There was size, colour, spangle, cap, and all the qualifications of a good bird. I just missed it, my friend, Mr. Hooke, having visited the green baize table before me. Mr. Harrison's 473, second prize, was another splendid bird, palish in colour, but a beauty, and Mr. Tuckwood's, 480, third prize, did not belie his judgment of what is requisite to constitute a high-class Lizard.

Among the Jonque Cinnamons were some unusually good birds, Mr. Etherington's 489 and 488, first and second, being stars, while Mr. Waller's hen, No. 505, well earned her third place. Someone on the look-out for a good thing secured her at £1. Northampton was in force in this class too, and in Buffs took all three prizes, Barwell & Golby's immense bird standing first. No. 537, Wallace & Beloe, very highly commended, was a gem of a hen.

Variegated Cinnamons were few in number, and nothing extra in quality. Something must be done to save this class of Canaries from becoming defunct. The north-countrymen who breed for size, shape, and marks, altogether irrespective of colour, though glad to get it when they can without sacrificing exact marking, grumble when a broken bird, rich in colour and quality, stands before a long, slim, half-washed-out bird, having nothing to recommend it but its marks, which, however, from want of colour, frequently scarcely show themselves; and the southern school, which believes in colour, grumbles in its turn when its bright specimens are passed over in favour of a bird it repudiates. Each should have its own class, or the class intended should be distinctly described on the schedule.

There was nothing very striking in the Any other variety, in which a Manchester Coppy, a Don, and a Crested Cinnamon shared the honours.

A word about the classification of the Mules. When I submitted my suggestions as to the improvement of the schedule, I had no idea of my rough copy being accepted in detail; in fact, I knew nothing of its being accepted at all till I received a printed copy. But it appears there is a misdirected letter somewhere on its travels, which, if I had received it in time, would have given me an opportunity of working out in detail what I had intended as a suggestion merely.

My impression was that the fact of the existence of Clear Mules being known militates against large entries in the "Clear for choice" classes. There can be no doubt of it. Last year there were but two entries in Jonques and four in Buffs in the "Clear for choice" classes. Besides, the old arrangement was devised to meet the claims of Mules which, though not absolutely Clear, are nearly so, and have at the same time no pretensions to be placed among Variegated specimens. The ideal of a Mule for a "Clear for choice" class is (next to Clear) one which at all events must, at the most, have no more decided marks than mere ticks; indeed, the "lateral extension" of the franchise was accorded to these ticked birds as a premium for honesty. It was argued that to make a class for positively Clear birds was to offer a premium for dishonesty, and therefore the "Clear for choice" clause was inserted. But look at the difficulty which arises out of its adoption! It drives every other class of Pied Mule into the one pen "Variegated," a position in which it is simply an impossibility for nine-tenths of them to have a ghost of a chance of winning, because the Evenly-marked among them must bear the bell. I am quite aware that the whole difficulty can be swept away at once by making three classes instead of two—*i.e.*,

A—Yellow Goldfinch Mule (Clear for choice),
B—Evenly-marked ditto,
C—Any other class of ditto,

always bearing in mind that the Dark Mules form a class by themselves, and that the three above-mentioned apply only to Pied Mules, and also bearing in mind that there ought to be

such an explanation attached to Class A, as to allow of no misconception as to its meaning. Of the two "Clear for choice" Jonques of last year, one was Evenly-marked; and among the four Buffs there was at least one which had eye marks, a dark feather in the tail, and a saddle!

In dividing the Mules into two classes this year I meant to suggest that the one should comprise the Evenly-marked birds, and the other all the rest; and my reason for suggesting that the Clear birds should go into the "Any other class," was that there is more analogy between an irregularly-broken bird (in its various degrees) and a Clear one than there is between an Evenly-marked and a Clear one. From the Clear bird to the Ticked is but a step, and from the Ticked bird to one more or less broken is but a step, but no reasoning can bring a Clear and an Evenly-marked bird together. Either is perfection in its way, and either represents the head of two classes very wide apart; the one a class in which a body mark (as distinguished from flight or tail marks) is only a blemish capable of measurement, the other a class in which even a tick is fatal. My idea, therefore, was that if in the "Any other class" an absolutely Clear bird was found, it should receive a special prize, which should not detract from the value of those succeeding it, so that the probability of such being exhibited would not act as a bar to probable success. Even if a Clear bird received a first, leaving it to the rest to fight out the battle for second and third, I still contend that irregularly-broken birds of size, colour, and quality, would have a chance of scoring, since the number of absolutely Clear birds in exhibition can be counted on your thumbs, while the number of those which lay claim to be called "Evenly-marked" is such that it is simply an impossibility for irregularly-broken birds to approach within three steps of the top of the ladder. I maintain that though it is capable of improvement, even this year's arrangement is better than last, and has secured a much larger entry.

Mr. Doel was first and second in the Evenly-marked Jonques. No. 567, first prize, was a grand bird, large, graceful, rich in colour, lightly and evenly marked, and everything one could desire in a Mule. It was catalogued at £1000, but up to four o'clock on Monday had not been claimed! No. 568, second, was another fine bird, but decidedly inferior to 571 (Mr. Ashton, third prize), which must have lost from want of condition. It was very lumpy. No. 569 (Doel) was a fine six-marked bird, and 570 (Doel) either had St. Vitus's dance or was subject to fits. Mr. Stansfield's 573 is a pretty Mule, but, unfortunately, the eye marks stretch over the crown, detracting from the merit of a really excellent bird.

In Buffs Mr. Baxter was first with something in hand. His 588 is a great Mule, and will take a deal of beating. Of 586 (Stansfield), second, I am sorry I can say nothing. I have either made a mistake in my notes, or have overlooked it entirely, and the same with 585 (T. E. Jeffs). They must, however, have been something out of the common when such birds as 582 (W. C. Burmiston), 584 (J. Stevens), 591 (Needler), all birds of note, stood beneath them.

Mr. Ashton obtained a special prize in the "Any other class of Yellow" with a Clear bird. I have myself given it a first as a Buff, as have other judges. Mr. Doel says it is *either*. In that case it is *neither!* But it is a very useful bird, which can win in two classes. On the wings and breast it is very high-coloured, but the head and neck is decidedly Mealy. It is a splendid bird. Mr. Doel monopolised the rest of the honours with a portion of his extraordinary stud. His 595 was a blaze of colour, and had a most perfect cheveral head; ditto 596.

In the corresponding class of Buffs Mr. Doel was first with neither more nor less than an "Evenly-marked" bird. A majestic Mule it is; but if a distinct mark in front of each eye does not constitute even marking, what does? On the assumption that these marks (which, though decided, are faint) are regarded as simple ticks, and that the bird more closely approximates to a Clear Mule than to anything else, the award is justifiable, not else. No. 614 (Ashton), good, one black feather in the tail being its pass. No. 621 (Jeffs), a nice bird, too, and 613 (Doel), looked very pretty, with good eyes and saddle.

I need hardly say that Stevens "walked in" with that awful Dark Jonque of his, and that something remarkable will have to be bred before Mr. Spence and Mr. Stevens can be deposed in the Linnet Mule class.

Remarkable hybrids were exhibited in the "Any other variety of Mule" division, in which, to some extent, the question of beauty of plumage is ignored in favour of rarity or singularity. It is a class in which everything is left to the Judges' discretion. But how a very inferior "Greenfinch and Goldfinch" could supplant the glorious "Bullfinch and Goldfinch" Mules is a thing no "fellah" can understand, and appeared to excite considerable surprise. Of hybrids which one has never met before it would be absurd to express an opinion, but their genuineness ought to be ascertained beyond a doubt.

The groups I must pass, wondering the while why neither of Walter's three splendid lots was deemed worthy of even an extra third, and how the six white hens came to be second.

The "miscellaneous" might well be dispensed with, and Mr. Gardiner's aviary, which was crammed with lively little chaps, suggests what might be done if a class for aviaries was substituted.

I have already extended this notice to an unreasonable length, and must pass the British birds without comment. The foreign birds are not my speciality, but Mr. Judd drew my attention to a Grey Parrot, which he said "had eaten his ticket because he was ashamed of it!"—W. A. Blakston.

LARGE versus SMALL HIVES.

Your correspondent under the *nom de plume* of "The Bee Hive" writing on this subject states that his experience, acquired during three years' observation of ten Woodbury hives, seems to prove that only eight of the ten frames composing a full-sized hive are ever in use at one and the same time for breeding purposes. My own experience has been, that not only are the whole of the ten frames in the stock-box frequently occupied by brood in various stages of development, but that several combs in a large super may in addition be almost entirely filled with brood. It may be a question of district, but it certainly is a question of the bee-master's keeping-up his stocks to the utmost point of population. With moderately strong colonies, the side combs, and possibly too large a proportion of the more central combs, are filled by the bees with honey, so that the queen is not able to use them for the deposition of her eggs. I have known, when an early honey harvest has set in, even the central combs to be almost entirely filled up with sealed honey, thereby paralysing the powers of the queen, and seriously affecting the prosperity of the colony. Your correspondent, if he had removed the two combs he states to have been full of honey, and had substituted frames with empty combs in their stead, would in all probability have found that the queen, if of average breeding capacity, would have at once appropriated nearly every cell for her own use, to the ultimate very great benefit of the colony.

Lest it should be supposed that I use small hives, I may state that my own ten frame hives are of considerably greater internal capacity than the Woodbury hives; in fact I always considered my late friend had adopted too small a hive for moderately good honey districts. Noticing how frequently prolific queens occupied every available space in my stock hives, a few years since I determined to endeavour to test their breeding powers to the utmost. I therefore constructed a box about 2 feet 6 inches in length, by 15 inches in width, to hold twenty-one frames of my ordinary boxes, the entrance being at one end, into which I hived a strong swarm. The queen was a hybrid Ligurian and very prolific. All the frames except the last three were more or less filled with comb, when a splendid swarm was thrown off. I examined the combs, and counted thirteen of them more or less occupied by brood, with by no means a large quantity of honey. To prove that honey was abundant, another hive in the same garden that summer gave a super of 75 lbs. The following season I altered this mammoth hive by fixing two division boards, having longitudinal apertures for communication, which I was enabled to open or close at pleasure. The central compartment held nine frames, and the two side ones five frames each. A colony was transferred into this modified arrangement of a Nutt's hive. The following year the communications into one of the side compartments were opened and some frames with comb added. These were quickly filled with eggs by the queen, and every comb was in use for breeding at the same time. A super was placed on the top, and subsequently removed with 40 lbs. of honeycomb. This last experiment was carried out almost in the centre of the city of Exeter—not, it would be supposed, the most favourable locality.

To sum up: I believe it comes to this, that a prolific queen with a sufficient number of subjects, can fill almost any amount of available comb with eggs. Of course it is obvious that no more brood will be hatched out than the population present can properly attend to, nor can such combs be made use of for brood if already filled up with honey. The prudent bee-master, therefore, who uses frame hives, will see that his breeding combs are not clogged up with honey.—S. Bevan Fox.

Your correspondent "The Bee Hive" asks for my opinion on this subject in connection with his proposal to use "Dummy Frames," by which I suppose he means frames of solid wood introduced into the larger-framed hives so as to contract the space. I have used them myself in former years, and they

answered the purpose very well, but on the whole I preferred using the super over a smaller hive. I find that it is merely a question of season or fertility of queen, whether the outer combs I and 10 are used for breeding or for honey. One year they will be filled with brood and the next with honey. Of course, if you give them twelve or fourteen combs there will be less chance of the outer ones being occupied with brood. My own hives, which are long and narrow, the combs running crosswise, were last summer filled with brood from end to end, in all cases where the honey of the year before had been eaten out, as well as from side to side. Some of these hives are 16 or 17 inches long in the clear. If the summer had been prolific in honey the outer combs, as the year before, would have been full of honey. Latterly I have shortened the length of these hives by a couple of inches, preferring to force the bees to store any excess of honey in the supers. But I do not find, even when the queen breeds in the supers, that it makes any practical difference in the amount of egg-laying that goes on below.—B. & W.

VENTILATING HIVES.—In the Journal of February 8th Mr. Bevan Fox mentions perforated zinc placed on the top of the hives to let out the damp air. I quite agree with him. All my bees are alive in the wooden boxes that had the perforated zinc on their tops, but in one without the ventilation the bees are dead. The combs in it appear greenish and mouldy. The floor-board appears dry, but slightly mouldy.—BURTON JOYCE.

OUR LETTER BOX.

APPEALING FROM THE JUDGES' DECISION (*An Exhibitor and Committeeman*).—The rule, "No appeal from the decision of the Judges shall be entertained upon any grounds whatever," only applies to appeals from dissatisfied exhibitors. If fraudulent trimming, pinning of combs, and fastening-on sickle feathers are detected on prize birds, even after the Judges are gone, we think the prizes should be withheld, for the exhibitors have violated another rule—He who claims equity must do equity.

WHITEHAVEN POULTRY SHOW.—Mr. J. Walker says that he had only just received the cock that had a pin thrust through his comb, and that nothing was done in the way of trimming whilst the bird was in his possession. The other two exhibitors whose birds were disqualified, because trimmed, say the same about their birds. It is no excuse, for they should all have examined their birds before they sent them to the Show.

DIARRHŒA IN HENS (*A Lover of Poultry*).—We do not like your feeding. We tried Corn Exchange sweepings, and found them expensive and unsatisfactory food. You never know what they contain. We care little for toppings or middlings. If you will give ground oats or barleymeal slaked with water in the morning, table scraps or Indian corn at midday, and a repetition of the morning meal in the evening, discontinuing all inventions and stimulants, your fowls will get well. If you continue your present management they will all die. Let them have cabbage leaves or lettuces, or some other green food, whenever they cannot have the grass run. None is so good as a sod of growing grass.

SPANISH COCK'S COMB UNDEVELOPED (*E. H. B.*).—Sell him; he will make little, because a shrivelled comb in a Spanish cock is indicative of internal disease, and is a symptom of "black rot," to which this breed is subject, and from which they never recover.

BRAHMA COCK (*Brahma*).—In all competitions of animals it is an axiom that, as the best is not too good, that which is faulty is not good enough. You wish to breed prize birds. You will not do it with a cock that has two capital defects—vulture hocks and lop comb. Take him from the hens at once, if you have not done so already.

BREEDING SPANISH FOWLS (*W. E. S.*).—A Spanish cock with a lop comb is worthless, so is a Spanish hen with an upright one. There is a proverb—

"A whistling girl and crowing hen
Are neither good for ; ards or men."

To breed perfect birds both parents must be so. The comb of the cock must be faultlessly erect, that of the hen must lop over. The crowing hens are only nuisances and should be got rid of at once. They do not lay, and the apparent alteration of sex is caused by internal ruptures that render laying impossible. Spanish are more prone to this fault than any other breed, and when we see a hen's comb go up we put her in the pot.

DESIRED FOWLS (*Digitatis*).—The fowl that will come nearest to your description is the Brahma Pootra, because it realises the last requirement—most easily keep. A fence 3 feet high will keep Brahmas in confinement. Spanish, Hamburghs, and Crève-Cœurs are all hand-some, they are excellent layers, but do not sit. We know no fence that will confine either of them. The only way is to keep them covered-in at top.

EXPORTING FOWLS TO QUEENSLAND (*K. M. H.*).—If your friend takes the fowls in charge you need not ship as much food as if they went alone, because he can always get scraps from the steward, and secure them food in odd bits. To guard against accidents you will do well to provide yourself with fourteen bushels of barley, and two bushels of gravel, or three if you can take it. It will help you to keep them in health if you take out some rape seed, and from time to time make it grow in your cabin in wetted flannel.

STARTING LIGURIANS—SIZE OF WOODBURY HIVES (*J. L.*).—You had better write to Messrs. Neighbour, of Regent Street, London, who will be able to supply you with either Italian queens or with stocks, and will also give you the necessary instructions as to your subsequent method of procedure. We think you are mistaken in supposing eight-frame Woodbury hives superior in your district, or any other, to the ten-frame boxes. If by judicious management you keep your colonies up to the greatest possible strength, we think you would find that your ten-frame boxes would prove far more remunerative than the smaller ones, both swarms and honey-yield usually being proportionately larger.

PAINTING STRAW HIVES, &c. (*L.*).—We have a strong objection to painting straw hives, though Mr. Payne and others recommend it. We have tried both that and covering them with Roman cement, and the bees did not thrive well under either. The latter was, however, much the more palpably injurious. Mr. Payne recommended the hive to be painted stone colour. We do not know the maker nor the price of the Cambridge Hive.

REMARKS.

21st.—Very fine all day with fine sunset.

22nd.—Early part rather cold, but dry all day, though not so bright as yesterday.

23rd.—Heavy rain from 6 to 9 A.M., damp morning, and very dark, cleared about noon, shower at 4 P.M., but fine evening.

24th.—Rainy and dull morning, rather finer in middle of the day, but showery and damp.

25th.—Rain in the morning and about 5 P.M., sunshine in the middle of the day and evening.

26th.—Rainy morning, fine about noon, dark in early afternoon with partial showers, wind changed to north.

27th.—Fine bright day though rather cold, a slight shower about 11 A.M., but all else bright and dry. "Queen's weather."

Although the sun is now gaining power, its influence is at present quite superficial, as will be seen by comparing the average temperature in sun with that of previous weeks, and then similarly comparing the temperature of the soil.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 28.

PRICES of rough out-door produce have somewhat receded, and the supply continues heavy, orders from the northern markets having failed to clear out the dealers' stands. Hothouse fruit is sufficient, although the supply of Pines is rather limited, but we are still having some fine fruit from St. Michael's, which takes their place, the quality being very superior.

POULTRY MARKET.—FEBRUARY 28.

The supply is rather shorter, and the spurt given by the Thanksgiving-day having caused rather a large demand, a rise has taken place. We do not think it will be maintained.

From observations taken near London during forty-three years, the average day temperature of the week is 49.5°; and its night temperature 32.1°. The greatest heat was 67°, on the 10th, 1826; and the lowest cold 7°, on the 10th, 1847. The greatest fall of rain was 0.60 inch.

HARDY AND EXOTIC FERNS.

Is there a lover of gardening and of the graceful in nature, who does not admire the finely-cut feathery plumes of hardy and exotic Ferns? We admire them wherever we find them, whether if climbing up the steep hill-side we meet with the Mountain and Three-branched Polypodies, or scrambling among the loose and crumbling rock at its base we chance to light upon the Allosorus crispus, growing among the fragments in dense tufts like finely-cut Parsley. From mountain sides we ramble into shady dells where we are at home amongst the nobler-growing of our native species, the broadly-arched compound fronds of Lastrea dilatata, the robust Male Fern, Lastrea Filix-mas, and its graceful companion, most exquisitely beautiful of all British species, the Lady Fern. Let us walk along the seacoast, and hanging from precipitous and inaccessible rocks, braving winter's cold and summer's heat, we find the dark-green-foliaged Asplenium marinum.

All our native species are amenable to cultivation. Some of them will thrive under very adverse circumstances, but for others careful culture is necessary. Growing as they naturally do in such totally different places, a somewhat different course of treatment should be given to each, although it is not essential to imitate Nature closely. I have dug up the Allosorus crispus from the exposed side of a Scottish mountain, where it was growing in little else but powdered rock, and it throve perfectly planted in deep rich peat on the north side of a high wall in the suburbs of London. The Asplenium marinum, growing on exposed rocks on the east coast of Scotland, will not live through the winter in the same neighbourhood, and barely exist in summer; but if potted in turfy peat and loam, and placed in a warm moist atmosphere, such as that of a plant stove, it will soon make a handsome specimen, and throw-up luxuriant fronds 18 inches in length. Another very interesting native species is the Ceterach officinarum, or common Scale Fern. It is generally found growing on old walls; indeed I do not know that it has been found in any other position. It flourishes in a shady part of the greenhouse, in a pot half full of drainage, with a compost of equal parts sandy loam, rough mortar rubbish, and pieces of broken bricks. As to the more robust species, such as Polystichum, Lastrea, Athyrium, &c., they will grow anywhere if the soil is suitable, and if they do not suffer from lack of moisture in summer. Some of the rarest of them well deserve a place under glass, such as the many fine forms of the Lady Fern, some of which are unsurpassed for pictorial effect. Grown in pots as Messrs. Ivery and Son, of Dorking, and Mr. Chaff, gardener to A. Smee, Esq., of Wallington, staged them at South Kensington last year, they have a fine effect. Athyrium F.-f. cristatum, Vernoniæ, pulchellum, plumosum, and Iveryanum are very distinct forms. For pot-culture they are quite as interesting, and rival in beauty (if they fail to do so in majestic appearance) the stately tree Ferns of the antipodes.

To grow hardy Ferns in perfection a humid atmosphere is necessary, and when they are making fresh growth the house which holds them should be shut-up in the afternoon, and the plants syringed through a rose. Under such circumstances the young fronds develope themselves as if by magic, and are a source of much enjoyment to those who take an interest in this class of plants. Ferns from warm latitudes, as a matter of course, require a higher temperature—55° in winter is a good medium for them, and from 65° to 70° in summer is essential as a night temperature. Nearly all the species luxuriate in a compost of equal parts turfy loam and tough fibry peat, with the addition of a fair proportion of silver sand and a few lumps of charcoal. It is of vital importance that the drainage be perfect, as the Fern, though a moisture-loving plant, dislikes stagnant water about the roots. The potsherds used must be clean, and placed with the convex side downwards, the largest pieces at the bottom, the smallest at the top, and over this some fibry material must be placed to prevent the mould used in potting from mixing with the drainage. In potting press the compost in firmly, but not so much so as is done with fruit trees or hardwooded greenhouse plants. Overpotting should also be avoided, as, indeed, this is frequently the cause of failures. The fresh compost gets sodden with water before the roots can ramify into the mass, and mischief ensues.

Then with regard to propagation. Some of the species are very easily increased by division, and it is thus that most of the Adiantums and Pterises are reproduced. Take, as an example, that most useful of all the Maiden-hairs, Adiantum cuneatum. We are continually using its delicately-cut fronds for hand, button-hole, and other bouquets, and well-grown plants of it are always ready for dinner table and general in-door decoration. You may take a large plant, and with a knife or small trowel divide it into a dozen pieces, which if put into small pots, and placed in a close moist atmosphere and a stove temperature, will each make a nice plant in a few weeks. Some species grow with a single stem, and therefore cannot be divided. Of these the Lomaria gibba is one, and a very desirable species. It is very freely propagated from spores, about sowing which there is no need to trouble, as, if they are allowed to ripen, the young plants will be plentiful enough. However, should a large quantity be required, it is as well to sow them. Seed-pans or ordinary flower-pots should be used for this purpose. Drain them well, and fill-up with the compost already recommended, but with the addition of a third part of pounded bricks. The spores when matured should be placed on the surface, and, after being watered with a fine rose, covered with a square of glass to maintain a moist atmosphere.

I will now enumerate a few of the most desirable species for stove and greenhouse decoration. Of late years many new species and forms have been introduced to our notice. Adiantums are amongst the most valuable for general decorative purposes. A. cuneatum is the most generally useful of the whole. A. farleyense must

be in all collections. A well-grown specimen is worthy of all the commendatory superlatives that can be bestowed upon it, but to keep it in good health a position free from draughts must be chosen for it in the stove. A. Sanctæ-Catherinæ is a free-growing species, and makes a noble specimen for exhibition. A. formosum succeeds in the greenhouse, and the fronds last a long time after being cut. A. colpodes is a very free-growing, pretty, greenhouse species, and has the young fronds tinged with red. A. tinctum has the young fronds more deeply tinged than in the above, but it is not free-growing. But by far the best of the tinged or tinted species is one I met with the other day in the nurseries of Messrs. Veitch, at Chelsea. It is of free growth, the fronds are much larger and more elegant than those of A. colpodes or A. tinctum, and of a deep red colour in a young state; it is named A. Veitchianum. I remarked at the same time A. peruvianum as a noble-growing species allied to A. trapeziforme. It will, no doubt, make a handsome specimen for exhibition, as it is of vigorous growth, and the fronds have a remarkably pendant character, giving the whole plant a distinct and fine effect. A. sessilifolium is also a very well-marked species of a deciduous character. The fronds are freely produced, and very handsome.

Amongst Aspleniums, A. cicutarium and A. formosum have very graceful recurved fronds, and are valuable table plants. Cheilanthes is a genus noted for its very elegant and finely-divided fronds. Davallia is also a noted genus with fronds of a very graceful character. At the head of this class stands the recently-introduced D. Mooreana. It is one of the most beautiful and valuable of Ferns, with gracefully-arching fronds from 2 to 3 feet in length, and half as much across. From the largest of the species we come to the smallest, D. parvula, a warm stove species, the fronds of which are only 3 inches in height, freely produced on a creeping rhizome. Gymnogramma has gold and silver fronds of a very distinct and striking character. The true G. chrysophylla is very handsome. G. Laucheana has fronds of the deepest yellow. The best silvery species I am acquainted with is G. peruviana argyrophylla; and next to it G. tartarea. G. Pearcei is an exquisitely beautiful species, with very finely-divided fronds of a distinct character. Leptopteris superba is a greenhouse Fern, and requires to be grown under a glass shade. It, however, deserves all the care that can be bestowed upon it. Lomaria gibba, and its variety Belli and crispa, must be in all collections. Then the Climbing Fern, Lygodium scandens, will find a place on account of its unique character. Todea pellucida and T. Wilkesiana require the same treatment as Leptopteris superba, and should have a glass frame devoted to them in the greenhouse. Amongst Pteris we would select P. serrulata, as it grows freely either in the stove or greenhouse, though the handsomest specimen I have ever seen was said to have been grown out of doors. These are a few names out of the many, and are selected from those I have cultivated, or those which have come under my own notice. The graceful Gleichenias are omitted because they require special treatment; and also the noble tree Ferns, as they require large structures to grow them in. Those I have named are all adapted for ordinary stove or greenhouse cultivation.—J. Douglas.

SPRING TREATMENT OF AURICULAS.

An observation made by one to whom we all as readers of the Journal are much indebted, and whose instructions we are generally ready to follow, Mr. W. Keane, has induced me to say a word or two on the above subject. I am very sorry to differ from so experienced an adviser, but I must fain do so. In his advice as to the treatment of Auriculas he says, "Let them have gentle showers," or words to that effect. Now from this I entirely dissent; and I maintain that the Auricula ought never to have a drop of rain, and least of all in the spring. Every grower of this beautiful flower knows that its greatest enemy is damp, and that his efforts are directed to the great end of giving it a free and open situation, keeping it free from drip, and not allowing water to settle in the heart of the plant. Unless you are for ever near your frames, it is impossible to do this and yet let them have any rain. If you leave directions with your man that they are to have only gentle showers, you will find some day to your cost that his idea of a gentle shower differs very widely from yours; just as my old man at Deal, who, when I told him they must not be exposed to too much cold wind, shut them up close, burned them up, and then told me calmly he thought the maggot had got to them. Hence, for the safety of your collection, I strongly advise no showers. But even if you allow them to get rain under your own eye, the drops will settle in the heart of the plant, and then canker and decay take place. Rain may possibly run off the plain-foliaged plants, but those with the mealy foliage retain it very pertinaciously, and nothing will free them of it except taking the plant up and blowing the water off. Then, too, I think that to allow the mealy-foliaged plants to become spotted with rain entirely destroys their beauty. I grudge even when watering that the outside leaves should get any on them, and should sadly grieve if the beautiful young leaves were to be thus injured.

I should like to know if all Auricula-growers share my opinions on this point. I have before me a letter from a son of that (in his day) well-known florist, Dr. Horner, who has evidently imbibed his father's taste, and is an enthusiastic florist. He says, "Even in this fine bracing air I never allow my Auriculas to have wet overhead. I do not even like my mealy grass splashed at any time, nor a wet heart for even a day among any of them." I know, too, that this is the opinion of the veteran grower George Lightbody.

I hope Mr. Keane will pardon these remarks on so small a point, but as I believe it to be one of importance to the successful growing of this lovely spring flower I could not well be silent.—D., *Deal.*

CHEAP SPRING GARDENING—PLANTS TO BE RAISED FROM SEED.

Plants of which the seeds should be sown in a border rather thinly a month hence, or in pots, boxes, or pans now, placed in a pit or cold frame, and the seedlings to be pricked out afterwards, and then transplanted in the autumn or early spring:—

Anemones, of the coronaria and the hortensis kinds. Many will show bloom in autumn.

Arabis (Wall Cress), several kinds, prick out and lift in autumn.

Bellis (Daisies), white and red are most useful. Prick them out, and many will show their colours in autumn.

Cerastiums. Good for carpeting and edgings. They are best propagated by cuttings, which if planted in a border will soon root. Seedlings to be pricked out.

Cheiranthus (Wallflowers). Sow in the open air. Prick out and move in autumn to the place.

Eranthis (Winter Aconite). Sow as soon as the seeds are ripe. In the first, and especially the second autumn, they will be fit for the flower garden.

Myosotis (Forget-me-not). Sow in June and July, prick out, and then lift where wanted. There are several good varieties, white and blue.

Primroses sown in April and pricked-out, will make strong plants by the autumn. Polyanthus the same.

Violets (Sweet), are most readily obtained from divisions planted and then lifted, but the single varieties also come up freely from seed, and the seedlings will make good plants before the spring. I find, however, that cuttings or divisions bloom most freely.

Pansies. Many, such as the Cliveden Blue, Yellow, Purple, and White, come rather true from seed. The English and Fancy or Belgian varieties are easily raised. Sown in July and August, not too thickly, they would show their colours so as to be transferred to the flower-beds in autumn and spring. Seeds to be sown in summer and autumn, and the seedlings lifted in patches for the flower garden late in autumn or early in spring.

Collinsia bicolor, grandiflora, and verna. The end of August would be quite early enough.

Erysimum Perofskianum. Rather lanky, about 2 feet high, but the flowers of a fine orange colour. The beginning of September will be soon enough to sow.

Iberis (Candytuft), of all the colours will be early enough if sown at the beginning of September.

Lasthenia californica. Sow at the same time as the preceding.

Limnanthes Douglasii. The same remark applies to this.

Myosotis. Different colours of Forget-me-not. For spring blooming, sow from June to August.

Nemophilas. The whole are worthy of a place in a spring garden, though insignis is the best. Sow at the beginning of September, and transplant in patches.

Saponaria calabrica, calabrica alba, and the dwarfer ocymoides are useful. Sow at the end of August, and lift the seedlings in tufts in autumn or early in spring.

Silene pendula, pendula alba, ruhella, Schafta, and other dwarf kinds, may be sown at the end of August and the beginning of September.

I have omitted, I find, two useful annuals, Sweet Alyssum, or Alyssum maritimum, white and rather straggling, but it stands pruning well, and smells like so many exposed honeycombs.

Sown in September it will lift well in patches in autumn and spring.

Eschscholtzia californica, crocea, alba, and tenuifolia are very gay plants. If sown in spring they will bloom in summer and autumn. Sown in July and lifted, they will bloom early in spring.

Most of the foregoing annuals will do best if lifted not singly but in patches, say six or more plants in a patch, with a little ball of earth about them. In somewhat stiff soils they need little more than to be sown on a fine surface, and to be covered with light sandy soil. In light soils I find it a good plan to dig the soil, tramp it rather firm, stir the surface to the depth of 2 or 3 inches, and incorporate with it some rough fresh loam and leaf mould, or rotten dung. Pat the surface even, but not hard, sow the seeds, and cover with some fine soil. With the ground thus prepared the plants may be raised with a trowel in little tufts or patches, with the rough soil adhering to the roots, and they will scarcely suffer from the removal when transferred to beds or borders.

So much for sowing for flower gardens in spring, but if you mean to enter on the subject at all seriously and to any extent, the best advice I can give you is to obtain "Spring and Winter Gardening," by Mr. John Fleming, which you can have by post for 2*s.* 7½*d.* I should have little faith in any Coleus planted out except the brown Verschaffelti.

I find I have omitted red and white Virginian Stock, which for spring blooming should be sown from the middle of September.—R. Fish.

SETS OF EARLY POTATOES.

I have lately seen it seriously recommended to rub off all the forward shoots, and then plant as the eyes are again beginning to show. This can only be justified as being the least of different evils. I would never allow a shoot to be removed from early Potatoes, but would have them in the ground before these stout shoots were more than 3 inches in length. I should like to have seed early Potatoes set close together, but singly, on platforms or open shelves, if only a foot apart; and in such a position, and kept merely secure from frost, the tubers would shoot strongly but late, and there would be no necessity for lessening their strength by rubbing off the shoots.

In these modern days, and under the system of modern gardening, the old gardeners would be unable to find shelf-room for their flowering bulbs and tubers, let alone doing justice to their seed Potatoes. In the majority of gardens where there are even show plant-houses there is a great want of room for storing.

I may here add that after having tried all kinds of sets for Potatoes—cutting them into pieces, each having one good eye or bud, as I should most likely do in the case of a new expensive kind, using the bud with merely a slice attached (the bulk of the tuber being used for food), and even propagating by rooting shoots, as we would do with a Dahlia—the results of my practice are simply these, that a middle-sized tuber entire gives on the whole the earliest and heaviest returns. If the different eyes begin to move it is well, however, to rub off all except one or two of the strongest. I say advisedly one or two, because, though I have planted rows close together, one having sets with one eye and another with two eyes, I could not satisfy myself by the size of tubers, weight, or measure, which was the better, but I found the crops in either case earlier and better than when I put a tuber in and left the different eyes to struggle with each other for the mastery. If I have any preference at all, it is to have one shoot from a tuber instead of two or more.—R. F.

GRAFTING.—No. 4.

Side Grafting.—Under this head M. Baltet treats of two modes of grafting—one, which he calls sub-cortical, or under the bark, in other words between the bark and the alburnum; and the other on the alburnum. For all practical purposes they might have been embraced under one head, for all grafting to be successful must be on the alburnum. However, we shall for the present adopt these distinctions of M. Baltet, and treat the subject after his method.

Sub-cortical Grafting.—If we wish to implant a twig on the side of a stem or under its bark, the stock ought to be in a state of growth. The operation is done—1st, from April to May at the rising of the sap, and then it is called, by an active bud; 2nd, from July to September, when it becomes a graft by a dormant bud. In the former case scions of the previous year are employed which have been laid in the earth with a northern exposure, or in a cellar, to preserve their vitality. The sap being in action in the plants at the time they are used, the graft will be developed in the course of the same year. In the second case (from a dormant bud) where the graft will be developed in the following year, a shoot of the current year is chosen, and is taken from the parent tree at the time of grafting, the leaves being removed if the tree employed is deciduous. Scions taken from evergreen trees should not be cut from the parent tree till they are required, neither ought the leaves to be removed. For these two methods, the summits of the twigs with a terminal head form excellent scions.

There are two systems of sub-cortical side-grafting, one having for a scion simply the fragment of a twig; the other a twig with a heel or shield, such as is used in autumnal budding, taken from the branch which produced it.

Side-grafting with a Twig.—This process is important for restoring defective trees, to obtain branches where they are required, and to change old varieties. It is equally useful for propagation. The woody scion is better adapted to inoculation under the old bark than the single bud generally used. The scion is a small twig, or the fragment of a twig, from 4 to 8 inches long, the inferior half of which is cut slantingly without a tongue to disturb the plane surface of the cut, which is cut then towards the point B. If it is desired to get a branch forming an open angle with the stem which bears it, a crooked or curved scion is chosen; the cut, on the convex part being applied to the stock, will give the summit a direction outwards. With a straight scion it will suffice to preserve a bud on the back of the cut, the growth of which will form a branch nearly perpendicular to the stem.

In the propagation of certain trees, as the Beech, branching scions are employed of two or three years old, and in them the cut is made, as we have stated, then at the point. The scion being prepared, two cuts are made on the stock (A), forming an incision (C), like a T, right through the bark to the alburnum. The sides of the incision are raised, and the scion is slid into it, so that the top of its cut corresponds with the transverse incision on the stock. The graft is then bound with a ligature, and if there is imperfection in the union between the two parts, the action of the air is excluded with the leaf of a tree, or by the application of clay or grafting-wax.—Baltet, *L'Art de Greffer.*

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Bulbine Mackenii (Bulbine of MacKen). *Nat. ord.*, Liliaceæ. *Linn. arr.*, Hexandria Monogynia.—Sent from Natal by Mr. MacKen, and has already flowered two seasons in the Royal Gardens at Kew. The root and neck of the plant are clothed with matted red-brown filaments. The leaves are from 2 to 3 inches long, and from 1¼ to 1½ broad, smooth, rather fleshy, nerveless, and pale beneath. Raceme 6 to 10 inches long, with from twenty to thirty bright golden-yellow flowers on pedicels spreading out almost horizontally. Perianth segments extending out almost from the base, with green tips and a keel at the back. Ovary three-lobed; stigma minute.—(*Bot. Mag.*, *t.* 5955.)

Dendrobium tetragonum (Four-cornered Dendrobium). *Nat. ord.*, Orchidaceæ. *Linn. arr.*, Gynandria Monogynia.—A native of the wooded islets in Moreton Bay. Stems in a dense fascicle, from 5 to 16 inches long, acutely tetragonal, and gradually blending into a slender round stalk, which expands into a woody, globose, tuberous base, emitting roots that attach the plant to the bark of the tree it grows upon. Each pseudo-bulb has a pair of undulating, coriaceous, keeled leaves. Flowers a pale dirty yellow suffused with pink on a slender yellow peduncle. Two lateral sepals twisted and edged with red. Lip whitish, with transverse pink bars.—(*Ibid.*, *t.* 5956.)

Exanthemum palatiferum (Palated Exanthemum). *Nat. ord.*, Acanthaceæ. *Linn. arr.*, Didynamia Angiospermia.—A native of the hilly regions of Bengal. Leaves petioled, sometimes blotched with white. Spikes glandular, pubescent, recurved, many-flowered. Flowers subsecund, two-lipped, lilac or scarlet, with a yellow spot on the lower three-lobed lip.—(*Ibid.*, *t.* 5957.)

Cœlogyne lentiginosa (Freckled Cœlogyne). *Nat. ord.*, Orchidaceæ. *Linn. arr.*, Gynandria Monandria.—Stem stout, creeping, as thick as a swan's quill, clothed with rigid brown scales. Pseudobulbs erect, trigynous, smooth, green, up which the brown sheaths reach half-way. Leaves, two at the top of the pseudobulb. Raceme produced at the base of the last-formed pseudobulb. Flowers on a floriferous peduncle covered with convolute green scales, pale green. Lip white, with a broad ochreous blotch on the mid lobe; the margins of the lateral lobes are brown, and there are freckles of the same colour on the disk. Mid lobe with a broad flat claw, broadly trowel-shaped, undulate. Column slender, narrowly winged. —(*Ibid.*, *t.* 5958.)

Zonal Pelargonium Ianthe.—"The habit of the plant is moderately vigorous, the leaves neat, and marked with the characteristic zone, while the flowers are large, well formed, and abundantly produced in bold, conspicuous, nosegay-like trusses. The colour is very difficult to note, a peculiar bluish tint mingling with the crimson. We append the description given in the catalogue of Mr. William Paul, of Waltham Cross, by whom Ianthe, with several other fine novelties obtained by Dr. Denny—notably Wellington and Sir Charles Napier—was sent out. All three of these varieties were certificated at Kensington :—

"'*Ianthe*.—Flowers bluish crimson, the blue predominating in the lower petals; flowers of large size, good shape and substance, quite novel, and very beautiful; habit very dwarf and branching, with handsome dark green zonal foliage; colour of flower unaltered by rain or sun. Altogether the finest variety for bedding ever sent out.'"—(*Florist and Pomologist*, 3s.,v.,49.)

THE ORCHARD WORTH CARE.

It certainly pays to take a little pains with young trees, for what is there that is more remunerative than an Apple crop one year after another? Who among our readers would be willing to take $5 per tree for an orchard of young Apple trees just coming into bearing? We have now an orchard of six hundred Apple trees, covering a lot of 15 acres, that we would not have taken from our grounds for $3,000. Add five years more to them, and one will see what they will add to the land. It is the strangest thing to us to see farmers owning 100 to 200 acres of land, with barely enough Apples to supply the family; or, perhaps, an old orchard of one hundred to one hundred and fifty trees occupying 3 to 4 acres of land, from which they realise more profit than any 20-acre field they have, not planting more Apples, or, after they do plant them, not giving them the proper care. When will farmers see this in its true light?—(*Small Fruit Recorder.*)

THE ROYAL HORTICULTURAL SOCIETY.

March 6th.

There was again a good Show, though scarcely equal to the last, especially as regards the floral subjects for which classes were provided. The Camellias, in particular, by no means came up to our expectations, the plants not being of any considerable size. Messrs. Lane, of Great Berkhampstead, had the first prize for six well-bloomed plants, exhibiting in addition a collection in small pots. In Class 2, for twelve cut blooms, there was no competition; and in Class 3, for six cut blooms, Mr. Potts, gardener to J. Knowles, Esq., Heaton Grange, Bolton, had a first prize for a very good stand. Mr. W. Paul, of Waltham Cross, sent a fine collection of cut blooms not for competition.

There were classes for shrubs in flower, and for Lily of the Valley, but no exhibitor came forward. Of early Grapes there was likewise no exhibition, but of late Grapes some extraordinarily fine bunches were shown, and notably that which gained the first prize. It came from Mr. Potts, gardener to J. Knowles, Esq., Heaton Grange, Bolton, and was Alicante, large in bunch, closely set with full, plump, jet black berries, beautifully covered with bloom. Mr. Sage, gardener to Earl Brownlow, Ashridge, was second with Lady Downe's, very fine; and Mr. Bannerman, gardener to Lord Bagot, Blithfield, third with the same kind, also in excellent condition. Mr. Osborne, Kaye's Nursery, Finchley, sent Alicante, good; Mr. Donaldson, gardener to Lord Chesham, the same kind, very fine; and Mr. Hudson, gardener to J. C. Imthurn, Esq., Champion Hill, Camberwell, some fine Lady Downe's. For Asparagus, Sea-kale, and Rhubarb, one dish of each, Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, was an easy first with splendid Rhubarb, fine Sea-kale, and large Asparagus. Mr. J. Bray, gardener to W. A. Sanford, Esq., Nynehead, Court, Wellington, was second with good Rhubarb and Sea-kale, and fine Asparagus; and Mr. R. Gilbert, gardener to the Marquis of Exeter, Burghley, was third with fine Sea-kale and good examples of the other two subjects.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Mr. Tegg, gardener to John Walter, Esq., Bearwood, sent specimens of a new white Sprouting Broccoli, which did not receive the approval of the Committee. Mr. Gilbert, of the Gardens, Burghley Park, Stamford, sent specimens of Snow's Winter White, and of Myatt's Cape Broccolis. Messrs. Paul & Sons, Cheshunt, sent examples of a fine stock of Snow's Winter White Broccoli. Sir Walter Trevelyan, Bart., of Nettlecombe, sent dishes of Lemons, Citrons, and Oranges, which were much admired, and received a cultural certificate. Mr. Sage, gardener to Earl Brownlow, Ashridge Park, sent a dish of very fine Keens' Seedling Strawberries, which received a cultural commendation. Mr. F. Dancer, of Chiswick, exhibited a dish of Cox's Orange Pippin in fine condition, and although much beyond the season at which this Apple is usually kept, they were of excellent flavour. They were awarded a cultural certificate.

A pretty little variety of Maize, called Zea gracillima, was exhibited from Mr. Benary, of Erfurt. Two Smooth-leaved Cayenne Pines, weighing 6½ lbs. and 5 lbs. respectively, and produced from a plant not thirteen months old, were exhibited by Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, and received a cultural commendation. Mr. Donaldson, gardener to Lord Chesham, Latimers, sent a very meritorious collection of Grapes, consisting of large and remarkably well-kept bunches of Mrs. Pince, Gros Guillaume, and Alicante, They were awarded a cultural commendation. Mr. Osborne, Kaye's Nursery, Finchley, sent three small but well-kept bunches of Gros Guillaume, and received a cultural commendation.

Floral Committee.—Mr. J. Fraser in the chair. Messrs. Veitch sent a fine collection of Orchids, including a magnificent specimen of Dendrobium Farmeri; a number of plants of Odontoglossum Alexandræ with grand spikes; Epidendrum paniculatum; Odontoglossum triumphans, very fine; O. Andersonianum, cream and brown; the hybrid C. Harrisianum, very fine; and an Oncidium with long twining racemes of large brown and pale yellow flowers. Together with these were several fine Palms, an excellent specimen of Hippeastrum pardinum, and the pretty little Stenogastra concinna. Messrs. Veitch also sent a fine group of Roses in pots.

From Messrs. E. G. Henderson & Son, St. John's Wood, came a good collection of Cyclamen persicum in several varieties, and a new Asplenium.

Mr. Denning, gardener to Lord Londesborough, Grimston Park, Tadcaster, again contributed a beautiful collection of Orchids, particularly noticeable among which were splendid specimens of Cœlogyne cristata, Dendrobium nobile, Cattleya Trianæ, Cymbidium eburneum with five large flowers; Brassavola glauca, Dendrochilum glumaceum, Cypripedium Lowii, very fine, Lycaste Skinneri, and Odontoglossum membranaceum.

Messrs. E. G. Henderson sent a group of Caladium Princess Alexandra, with rose-tinged silvery leaves veined and edged with green. Messrs. Rollisson, Tooting, sent a mixed group, in which were Vandas, a fine specimen of Cypripedium villosum, and several other Orchids; Araucaria Cunninghami glauca, and a pan of Primula nivalis, a charming little white-flowered species. From the same firm came also Calamus verticularis, a handsome Palm, which received a first-class certificate. Mr. Herbst, nurseryman, Richmond, sent two large baskets of Lily of the Valley, beautifully grown and flowered. From Mr. W. Paul Valley, beautifully grown and flowered. From Mr. W. Paul came Waltham White Primula, with very large white flowers of great substance; this we have frequently noticed in terms of high commendation. Messrs. Standish & Co., Ascot, contributed an extensive and beautifully flowered group of Azaleas, Bouvardias, Spiræa japonica, Cinerarias, Hyacinths, cut blooms of Maréchal Niel Rose, &c. Mr. H. Bennett, Manor Farm Nursery, Stapleford, sent several of the new Hybrid Perpetual Roses.

Mr. Williams, Holloway, exhibited among new plants Toxicophlæa Thunbergi, a Natal plant with close heads of white flowers and dull green leathery leaves, also a magnificent specimen of Dendrobium Cambridgeanum, bearing a profusion of its rich yellow and brownish crimson flowers. In the same collection as this were a very fine specimen of Lycaste Skinneri, Tillandsia Lindenii, its deep azure blue flowers more lovely than ever, several Palms, &c. Mr. Williams also exhibited white Chinese Primulas of a fine strain, and some excellent Cyclamens, both in colour and freedom of bloom.

From Mr. Ware, Hale Farm Nurseries, Tottenham, came a charming collection of spring-flowering plants—such as the double white variety of Primula acaulis, Iris reticulata, Scillas, Dog's-tooth Violet, and many other gems.

From Mr. Green, gardener to W. Wilson Saunders, Esq., came a fine variety of Imantophyllum miniatum, called Cooperi, richer in colour and with a finer truss than the ordinary form. Mr. Green also exhibited the little white and pale yellow-flowered Eria obesa. Mr. Masson, gardener to R. Milne, Esq., Viewfield House, Arbroath, sent a magnificent specimen of Phalænopsis Schilleriana, with two branching spikes covered to the height of about 3 feet with beautifully-coloured rosy blossoms, 207 in

number. This splendid object received a well-deserved cultural commendation, and was recommended to the Council as worthy of a medal.

Messrs. Paul & Son sent a collection of cut Roses, and Mr. Meadows a wooden-ended and sided span-roofed hand-light, with sliding panes of glass, hinged so as to fold up.

First-class certificates were given to Messrs. Rollisson for Calamus verticularis; to Mr. Green for Imantophyllum miniatum Cooperi; to Mr. Williams for Toxicophlæa Thunbergi; and to Mr. William Paul for Waltham White Chinese Primula; cultural commendations to Mr. Masson for Phalænopsis Schilleriana; to Messrs. Veitch for Dendrobium Farmeri, for their collection of Orchids, also for their collection of Roses; to Mr. Williams for Dendrobium Cambridgeanum, for his collection of Cyclamens, Chinese Primulas, and group of Orchids; to Mr. Denning for a collection of Orchids; to Messrs. Standish & Co., and Messrs. Rollisson, for groups of plants; to Mr. Ware for spring-flowering plants, &c.; to Mr. Herbst for Lily of the Valley; to Messrs. E. G. Henderson for their collection of Cyclamens; and to Mr. W. Paul for a collection of Camellia blooms.

NOTES ON GRAFTING.

This will require to be done earlier than usual this season, unless the scions are kept dormant in a cool shady place. As a general rule the grafting will be most successful when the growth of the stock is a little in advance of the scion, more especially in the case of Vines. We have grafted successfully when both stock and scion were in a dormant state, but the scions did not take so quickly as when the stock was cut down after being in leaf, and the retarded scion was put on before it showed signs of moving. Of course in Vines, during the free flow of the thin watery sap before the leaves expand, grafting is out of the question. It must be done either when both stock and scion are in the inert state shortly before the sap is expected to move, or after the stock is growing, and the scion still inert, for after the leaves of the stock are near the full size there will be no more bleeding.

The modes of grafting are endless, and there has often been much unnecessary work attendant upon them in the way of notching, tonguing, &c. The most essential point is that the inner bark of the scion should neatly join the inner bark of the stock, and it matters little how this is done provided the scion is kept secure in its place, and the air, which might hinder the free and rapid union, excluded. Many plastic materials are used for this purpose, and are very useful for grafting small plants; but for general purposes, such as fruit trees, I do not think anything better than clay wrought to the consistency of putty and mixed with a little cow dung, the whole being tied over with moss to keep it from cracking. There is no simpler mode than side-grafting—that is, taking a slip 2 or 3 inches long off the stock, a similar slip off the scion, placing them close together, so that the inner bark may join, and tying them securely with matting or woollen thread. When grafting an old Vine stem we have often treated it as we would have done a large stump or branch of an Apple or a Pear—that is, inserted two or three scions round the stem instead of one. This tends to prevent one side of the big stem becoming dormant, and afterwards influencing the free current of the sap. In such cases we have taken out neatly triangular spaces from the stock, and cut the scions in the same shape, so as to fill the space neatly. In this, as well as in all grafting of Vines, we prefer that the base of the scion should be cut across through a bud space, and only one eye or bud should be left above. The space of two nodes is, therefore, wanted for a scion. For young Vines side-grafting is the simplest and easiest. When a change of kind is determined on, grafting gives two chances, as, if a graft fail, you can inarch on the young wood that will come afterwards from the stock as soon as that becomes a little firm.—R. F.

ENTOMOLOGICAL SOCIETY'S MEETING.

The second February meeting was held on the 19th at Burlington House, the recently elected President, Professor Westwood, in the chair. Mr. Frederick Smith stated that his attention had been called to some "silk waste" from Japan in a warehouse in London, which was much infested with mice. He had discovered that the waste silk cocoons contained dead caterpillars and chrysalids of the common Silkworm, upon which they fed. On examining some of the cocoons he had found that they occasionally contained two chrysalids instead of a single one. Mr. Jenner Weir stated that the same fact had been observed in Bombyx lanestris. Professor Westwood observed that the fact of two caterpillars joining to form one enlarged cocoon, instead of each making a single one in proximity with the other, exhibited a peculiarity of instinct similar to that shown by two or more swarms of Wasps uniting to form one gigantic circular nest; and Mr. Smith observed that this had been even done by different colonies of distinct species of Wasps working together, so that the outer covering of the nest showed layers of the different coloured materials used by each species. Mr. Butler exhibited a large grub-like larva, evidently that of an Ichneumon, which had emerged from a caterpillar of the Buff-tip Moth. It had spun a rough cocoon composed of black and white threads.

Dr. Buchanan White made some observations on the habits of a species of black Ant at Capri, confirming Mr. Moggridge's notes communicated to a former meeting of the Society. Their nest was underground, and the seeds which they stored were those of Composite and Leguminous plants. Occasionally several Ants would unite to drag along a single seed. Mr. Horne stated that he had observed a similar fact in the habits of some Indian Ants.

Professor Westwood exhibited type specimens and drawings of the animals from Madagascar upon which Latreille had founded his genus Prosopistome, supposed by that author and M. V. Audouin to belong to the Crustacea; and made some remarks thereon connected with the assertion recently made by Dr. Joly, of Toulouse, that these creatures and "le Binocle" of the neighbourhood of Paris described by Geoffroy are in reality the early stages of a species of Ephemeridæ. He was, however, scarcely able to believe that this assertion was founded on fact, but at present felt indisposed to express any opinion as to their actual affinities, which he did not, however, regard as decidedly crustacean. Mr. McLachlan also expressed a doubt as to the possibility of these creatures being ephemerideous, as they differed so entirely in their essential structure from the well-known characters of all other ephemerideous larvæ. He also exhibited specimens of Boreus californicus of Packard, from North America, a species twice the size of that previously described. Mr. Dunning announced the recent decease of J. C. Dale, Esq., one of the oldest British entomologists.

Mr. Miller read some remarks concerning the habits of certain gall-producing Sawflies of Salix fragilis, which are said to avoid those portions of the tree which overhang water. Count Osten Sacken had also observed in North America that the branches of stone-fruit trees over water were free from the attacks of insects; and Mr. Miller hence suggested a practical application in order to save choice fruit trees from the attacks of insects, by surrounding them at the base with glass, which, it is well known, is often mistaken by insects for water.

Training the Chinese Wistaria in a New Style.—Florists have discovered a process to make this plant grow in tree form so as to support itself. A young plant is first trained to a stake 6 feet high. When it reaches the top it is headed-off. The second year, or as soon as it is stiff enough, the stake may be taken away, and the young plant will support itself. It will never make running branches after this. A beautiful umbrella head is formed, with hundreds of drooping flowers in spring.

KEEPING GRAPES IN BOTTLES OF WATER.

The Grape-room at Aswarby Park is on the second floor from the ground, with an aspect to the north unvisited by the sun's rays, and possessing great dryness on account of its elevated position. I find that there are three great evils to be guarded against, and these are damp, frost, and artificial heat. My room is 21 feet long, 16 wide, and 7 feet 6 inches high, with the two outer walls looking respectively towards the north and the east. The walls are thoroughly plastered, as is also the ceiling, the latter three coats deep, and the floor consists of composition. Clean dry sawdust is strewn on the floor, and likewise on the top of the ceiling between the rafters, being intended in the latter case to keep out the frost. Two opening windows look towards the north, and are each fitted on the inside with shutters, which should be closed in severe weather, and the space between them and the window padded with any clean dry material. The door is single, and on the south side, but it can be converted into a double door when required, and the space between closely padded, as in the case of the windows. Thus the room is almost air-tight in frosty weather. All ventilation is effected by means of the door and the windows; and as fresh air, with a good amount of light, is required at all times, I open them whenever the weather permits. Should the day be damp and cloudy, or the wind in the north, I do not open the room, but otherwise I never lose a chance of admitting light and air, if only for half an hour. On the 8th of December, when we had 20° of frost, the temperature in the room did not fall below 38°, and this was with-

out the aid of artificial heat. As a rule, the temperature is nearly 48 , and this can with careful attention be maintained for weeks without artificial means.

At each end of the room are arranged fruit-shelves for the best varieties of dessert Pears and Apples, whilst the centre of the room is devoted to the keeping of Grapes. We have here eight standards, 6½ feet high and 2 inches square, into two sides of which are let, alternately, brackets 1½ inch thick, and which, after being thus fixed, measure 4½ by 3½. Four of these standards are placed on each side of the room, leaving a passage-way all round them. The bottle-receptacles are then laid on the brackets, so as to rest perfectly flat, and are made fast with one screw-nail driven through the under side of the bracket into the under side of the bottle-receptacle. A light facing of wood fitted on the front of the standard rests upon the receptacle, and fits under each bracket, thus preventing the receptacle from rising up behind, and giving the whole a neat and finished appearance. Each pair of standards has seven 10-feet lengths of bottle-receptacles, four on one side and three on the other, each length holding eleven bottles, so that each pair of standards carries seventy-seven bottles; it has also an iron spike in the top. There are two laths of wood along the top of the standards, with holes in them at the same distance as that at which the standards are placed, and bound together by means of an iron spike, which passes through the holes. *Fig.* 1 shows the standard. *Fig.* 2 shows the top of the bottle-receptacle. *Fig.* 3 gives a full-sized sectional view of the receptacle containing the bottle.

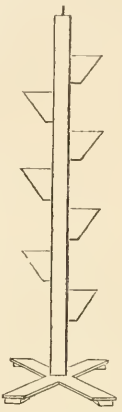

Fig. 1.

I have tried many different mixtures for filling the bottles, but I find there is none equal to charcoal and pure rain water, room, the use of sealing-wax or any other material is dispensed with, as the shoot becomes perfectly hard and dry, and will neither take in nor give off moisture.

I have the bottles prepared beforehand, and after cutting the shoots off at the second eye beneath the bunch, if possible, I carry the bunches, with all the green foliage untouched, to the storing room, and place them in their respective positions. This foliage should be allowed to die-off of its own accord, after which it must be carefully removed.

When I have put the first lot past I go to the vinery and make another selection, to come in at the proper time. Although this may seem a slow process to some, I am, nevertheless, perfectly satisfied in my own mind that it answers better in the end. The foliage was nearly all gone from the Lady Downe's when I cut them, but this autumn I intend to select them in the same way as I did the Muscats.

I think the time is not far distant when Grape-rooms will be as common as our fruit-rooms, and answer the end in view just as well, provided they are carefully attended to, for without this Grapes will not keep four or five months.—Richard Nisbet, *Aswarby Park Gardens, Falkingham.*

P.S.—The Muscat Vines were started on the 7th of March, Lady Downe's on the 27th of March, 1871. The bottles are all stoppered with wadding, as in *fig.* 3.

I have practised this plan for three years; I let the Grapes hang upon the Vines as long as possible, but never late upon one Vine two years consecutively. A Vine that carries fruit late one year is one of the first to have its fruit cut in the following season; thus the Vines have a rest every alternate year. Of course there are cases where it is desirable to cut the whole of the Grapes early, as where the house is required for plants, but this is done at the expense of flavour. If they are required so late as March or April, I think Grapes should not be cut sooner than the end of January, for they will not keep long with the ends of the shoots in water without loss of flavour.

On February 10th, 1871, I cut the last bunches of Alicante that ripened the preceding August. The ends of the shoots

Fig. 2.

close to which the stalk of the bunch of Grapes is placed, as shown in *fig.* 3. The Grapes should be cut as they ripen, and not taken off all at once irrespective of their exact condition. Ten or twelve days before I cut any bunches I went over all the

Fig. 3.

Vines in the Muscat house, trained on the extension system, the foliage of which was at that time perfectly green and healthy. From these I selected from forty to fifty ripe bunches, the shoots of which I shortened to two eyes above the bunch, at the same time letting remain what small laterals there were attached to these eyes. By thus cutting back the shoots ten or twelve days before taking the bunches to the were put in bottles filled with rain water, with a few pieces of charcoal added; the mouths of the bottles were then sealed up. The bottles were placed in a dry room, where the temperature ranged from 35° to 45°, the light was not excluded, and due regard was paid to ventilation. In this way the Grapes kept in fine condition until the end of April—no berries burst. After April 30th the footstalks began to shrivel, and the berries to shrink a little. I cut the last on May 12th, and the first new Grapes the same day, and though the old Grapes had been ripe nine months—six on the Vine and three in bottles, they were nearly as handsome as the new ones. There was an evident loss of flavour the last few weeks.

In reference to the Grapes that burst at Belton, may they not have been cut too soon, while the sap of the Vine was still active? It seems probable, if the shoots were put into water in that state, that they would have the power to take up moisture to such an extent as to burst the berries.—John Potts, *The Gardens, Heaton Grange, Bolton.*

BEAUCARNEA RECURVATA.

The subject of the illustration, Beaucarnea recurvata, sometimes known also by the name of B. tuberculata, is at once graceful and exceedingly ornamental. The genus Beaucarnea is of somewhat recent introduction, and belongs to the order Liliaceæ. At present there are but few species known, but those with which we are acquainted are all natives of the temperate regions of Mexico. Beaucarneas are remarkable for the bulb-like swelling at the base, and an arborescent stem. The swollen base in the species we here figure is nearly smooth, but in some others it becomes rough and woody, resembling somewhat the Elephant's-foot plant (Testudinaria elephantipes) of the Cape of Good Hope.

As an ornament to the conservatory, for giving a tropical effect to the out-door garden during the summer, or for hall decoration either in summer or winter, there are few plants to excel Beaucarnea recurvata, its ample spreading head of long

drooping dark green leaves affording a contrast which we seek in vain in any other plant. It is frequently remarked by both amateurs and gardeners that Beaucarneas have a grotesque but not an ornamental appearance. That such should be the case, however, is entirely the fault of the cultivation. Treat them liberally, and an ornamental, graceful, spreading crown of leaves will be developed; starve them, and they become simply ugly. This peculiarity is not confined to the genus

Beaucarnea recurvata.

Beaucarnea, but applies more or less strictly to nearly all the plants we have in cultivation; the fault lies mostly in their wants and requirements being very imperfectly understood, and their rarity and consequent high money value has prevented their owners from experimenting much with them.

I have had a great number of these plants under my care both in a large state and as seedlings; I shall therefore conclude these remarks with a brief summary of my mode of management, which has been very successful. I find that even in quite a young state, say when only a few months old, the plants begin to assume the bulb-like character at the base; but I am not able to arrive at any satisfactory conclusion as to

how long it takes to form such a plant as that represented, but I should imagine it would be about fifteen years from seed, providing the plant received uniformly liberal treatment. The soil should be rich fibrous loam, with a liberal admixture of sharp river or silver sand. Special attention must be paid to the drainage, which must at all times be in perfect order. The treatment for old plants should be during the summer, if standing in the conservatory, full exposure to the sun, and an abundance of water. I repeat the words, an abundance of water, for the plants may be almost kept with their roots in the water and their heads in the oven. As autumn comes on, gradually withhold water until, upon the setting-in of winter, you may entirely stop the supply, and keep the plants quite dry until the sunny days of spring again set them in motion. I prefer growing young seedlings in more heat, and not drying them quite so much until they get a few years old, when they may be placed upon the same footing as their elder relatives. —Experto Crede.

We are indebted to Mr. B. S. Williams, of the Victoria Nursery, Upper Holloway, for the illustration here given, the drawing for which was taken from amongst a great number of this class of plants which may be found in that establishment. —Eds.]

A USEFUL GREENHOUSE.

As almost everyone who can afford it now erects a greenhouse it may, perhaps, interest some of those who are about to build one, to hear the description of a greenhouse erected many years ago by a neighbour of mine, and which always seemed to me to give the greatest possible amount of enjoyment which a single structure can yield.

The house is a long lean-to with a south aspect. The monotony of such a construction is broken by a large bow thrown out at the centre, and from this bow a pent roof is carried to the back wall, thus forming a centre transept. Against the back wall there is a narrow border, in which are planted Camellias. These are trained to a trellis affixed to the wall. In the front of the house there runs a narrow shelf where bedding plants are wintered securely. Underneath this shelf are the hot-water pipes.

The area of the house is filled by two stages, which do not join, but leave the centre transept free, and leave also a roomy walk both at the front and at the back of the house. These stages are of only two or three tiers, and do not exceed 4 or 4½ feet in height, so that they do not take away from a person standing in front the view of the back wall. They are filled in spring with Hyacinths, Polyanthus Narcissus, and the like. In summer they might be employed in flowering Japan Lilies, Ismene calathina, &c. In autumn Chrysanthemums would create another summer. This year, even in an unheated orchard house, some few Chrysanthemums were still in flower at the beginning of February, until, one fine sunshiny morning, the lovely Iris reticulata suddenly burst into bloom, and told us that another year had indeed arrived.

In the bow already described, and between the two stages, were tall plants of Camellia in pots. The roof was covered with Vines planted in an outside border. The shade of these when in leaf was beneficial to the Camellias against the back wall, and in summer this shade was increased by tiffany stretched underneath the Vines. How this was removed when the Vines were attended to I do not know. In bad seasons sufficient heat was put on to ripen the Grapes in September, so that all, or the greater part, might be cut by the middle of October, when the bedding plants were brought in. The fruit would be kept some further time after its removal from the Vine.

From the above description it will be seen how much enjoyment the house afforded to a lover both of flowers and of fruit. But there remains one other pleasure, which to an invalid is most grateful—namely, sufficient length of walk where exercise may be taken in all weathers. I find an orchard house 50 feet long ample for this purpose; but the full amount of enjoyment can be obtained only when the greenhouse can be entered from the dwelling-house without the necessity of passing through the open air. In this one point my friend's structure was defective.—G. S.

Mr. William Paul, The Nurseries, Waltham Cross, gave a dinner of roast beef and plum pudding on Thanksgiving-day at which about fifty of his *employés* sat down, one of the greenhouses being fitted up for the occasion. After the usual loyal manifestations, the party adjourned to a large meadow adjoining the nurseries, where a huge bonfire was lighted, accompanied by a grand display of fireworks. The seed warehouse and offices were illuminated, the letters V. R. being placed on either side of the Royal arms, over which a crown was placed. Fully three thousand persons witnessed the display, and were freely admitted to the grounds.

ON THE INFLUENCE OF LIGHT UPON PLANTS AND ANIMALS.

By Cuthbert W. Johnson, F.R.S.

That light materially influences the growth and the colour of plants was an early observation of the cultivator. That they lost their colour when grown in the dark, that they extended themselves towards any opening of the opaque covering in which they were confined, could not long escape the gardener's observation. It was a much later remark that light influenced the health and the growth of animals, and a still later discovery that light was composed of seven different rays, and that these rays possessed different chemical properties.

Some recent observations of the effect upon the growth of the Vine by the violet ray add additional interest to our stock of knowledge as to the influence of light on the vegetable world. I allude to the report by the American General Pleasanton "On the Influence of the Blue Colour of the Sky in Developing Vegetable and Animal Life." His experiments originated from a conviction that the blue colour of the sky must have a very great influence upon the prosperity of plants and animals. "With this idea dominent in his mind," observes the able editor of the *Gardeners' Chronicle* (vol. 1872, page 175), "the General in 1860 erected a vinery; this was finished in March, 1861. It was a span-roofed house, 84 feet by 26, and 16 feet high, having an aspect nearly north and south. The borders outside and inside were of the ordinary composition, and 3 feet 6 inches deep. The roof was glazed with a row of violet-coloured panes between every six rows of ordinary glass, and these were made to alternate in position with those on the opposite side, so that the sun in its daily course threw violet light successively on all the leaves exposed to its influence. Cuttings of twenty varieties were planted in April, 1861. Their growth speedily commenced, and proceeded with a degree of vigour that excited very naturally the astonishment of the beholders, since the gardener had every day to tie up the new wood, which was not in existence the previous day. In September, 1861, some of the rods were 45 feet in length, and 1 inch in diameter at 1 foot from the ground! In January, 1862, they were pruned, and in March they began to push, and in the development of foliage, wood, and bunches they outdid their former year's growth. In September the weight of the Grapes was estimated by Mr. R. Buist, a well-known nurseryman, to be equal to 1200 lbs., from Vines, be it remembered, only seventeen months old. In 1863 the Vines yielded a crop estimated at two tons! And what is equally surprising, from year to year the Vines have continued to yield splendid crops without intermission, and are now in robust health."

These important researches, the report of which has attracted the attention of the Agricultural Society of Philadelphia and the Academy of Sciences at Paris, are too interesting to need any commendation of mine to the reader's attention. It is true that they present some startling facts, but then we must remember that we have long been aware of other phenomena with regard to the action of light on plants and animals equally difficult to explain. Thus, with regard to the action of light upon animals, why do the box, cellar, or stable-fed cows of London become diseased, though fed on the most nutritious and abundant food? Are they not kept in darkness? It is true that animals secluded from light fatten faster than those in the light, but there is no doubt but that their health suffers. The material effect of light upon animals is but imperfectly understood; yet there is no doubt that the brilliancy of the plumage of the birds and insects of warm climates is chiefly attributable to the intensity of the light to which they are exposed. In our own country, without light, the common cockroach, reared in the dark, becomes nearly colourless; tadpoles remain tadpoles. On the other hand, observes Dr. W. B. Carpenter (*Physiology*, page 54), the more the body is exposed to the influence of light, the more freedom do we find from irregular action or conformation. He instances the ill effects of the absence of light on certain wards of the hospitals, both in London and on the continent; and the absence

of all natural deformity in the natives of South America, who do not wear any clothing. In the experiments of General Pleasanton on some pigs and a calf, he thought that a decided advantage was derived from placing them under the influence of the blue ray. Then when we long since examined the action of light upon plants, we were met with many facts which excited our curiosity and anxiety for more knowledge than we possessed. As my brother, Mr. George W. Johnson, remarks (*Principles of Gardening*, page 252), plants are obviously stimulated by light. Everyone must have observed that they bend towards the point whence its brightest influence proceeds. M. Bonnet, the French botanist, demonstrated this by some very satisfactory experiments, in which plants growing in a dark cellar all extended themselves towards the same small orifice admitting a few illuminating rays. Almost every flower has a particular degree of light requisite for its full expansion. The blossoms of the Pea and other papilionaceous plants spread out their wings in fine weather to admit the solar rays, and again close them at the approach of night. Plants requiring powerful stimulants do not expand their flowers until noon, whilst some would be destroyed if compelled to open in the meridian sun. Of such is the Night-blooming Cereus, the flowers of which speedily droop, even if exposed to the blaze of light attendant on Indian festivities.

Then, again, light not only exerts a chemical action on plants, but it would seem that some of them appear to absorb it, or at any rate they emit it. This light, which plants and certain animals diffuse, has been the source of much discussion. That it is emitted from some insects—from decaying wood or fish, and even when pieces of lump sugar are rubbed together in the dark—is too well known to be denied; but that certain plants are also occasionally luminous in the dark has been disputed. The plants from which light has been emitted are the flower of the African Marigold, the Orange Lily, Nasturtium, the scarlet Verbena, and even from some of the Lichens. The emission of light from plants has been denied chiefly on account of the difficulty of explaining the fact. That objection, however, applies to the glow-worm of our hedges, to the meteorolites which are gliding through the atmosphere, and even to the summer or sheet lightning flashing around our horizon.

We have seen the effect of light upon Vine cuttings reported by General Pleasanton, and this is not the earliest evidence in our possession, for the action of light upon cuttings, as Dr. Lindley long since concluded, is hardly inferior to that of heat (*Theory of Horticulture*, p. 291). The moment light strikes a green plant it excites perspiration; and that the influence of different coloured rays of light upon plants is varied appears from other evidence than that of the American General. Thus, the Ferns at Kew placed under green glass by Dr. Hooker flourish with unusual luxuriance.

Although, as I before remarked, it is a modern discovery that the different coloured rays of light produce different chemical effects upon plants, that white light does so has been long known. The gardener is well aware how in its absence his vegetables become more watery. The chemist long since discovered that plants in the light emit oxygen and absorb carbonic acid gas, and so purify the air, which is corrupted by the breathing of animals, since animals absorb oxygen and emit carbonic acid gas. The keepers of aquariums are aware of this—they are careful to preserve a due proportion in these between the fish and the aquatic plants with which they tenant them. Plants, however, which are placed in sleeping-rooms rather tend to render it less wholesome, since they in the dark inhale the same oxygen gas as ourselves. These facts did not escape the notice of the celebrated chemist Davy, for in one of his works he remarks: "It may be said that, if in summer the leaves of plants purify the atmosphere, towards the end of autumn and through the winter and early spring the air in our climate must become impure, the oxygen in it diminish, and the carbonic acid gas increase; which is not the case. But there is a very satisfactory answer to this objection: in our winter, the south-west gales convey air which has been purified by the vast forests and Savannas of South America; and thus those events which the superstitious formerly referred to the wrath of Heaven, or the agency of evil spirits, and in which they saw only disorder and confusion, are demonstrated by science to be ministrations of Divine intelligence, and connected with the order and harmony of our system."

Prolific Hyacinth Bulb.—I have a very singular specimen of Charles Dickens Hyacinth, now in bloom. It has four distinct spikes, each about 8 or 10 inches long, full of flower, and all springing from the crown, not from offshoots. Each spike bears as many bells as an ordinary Hyacinth with a single spike. It is grown in a pot, in loam, &c. The bulb is of ordinary size.—C. W.

WHO RAISED THE RIBSTON PIPPIN?

"A Hull correspondent sends the following:—On the 1st of September, 1693, in the fifth year of King William and Queen Mary, Robert Clemesha, of Goldsborough, brought his son Robert to be bound apprentice to the Honourable Robert Ryerby, of Mettridge Grange, in the county of Durham, as a gardener. His master covenants to find him sufficient meat, drink, clothes, lodgings, and washing suitable for an apprentice. When bound he signs with a cross, not being able to write. The Honourable R. Ryerby had land near Goldsborough—I know from receipts for rent in my possession. Perhaps he lived at Ribston Park. In after-life Robert Clemesha was gardener there. He had given him the pip of an Apple brought from France, which he was desired to endeavour to cultivate. This he succeeded in doing, and the fruit was much approved and takes the name of Ribston Pippin, from the locality where it was first raised. The tree died in 1840. The indenture in my possession was ready to drop in pieces, so I had to glue it to cartridge paper, and have presented it to the Hull Philosophical Society, in whose museum it is now deposited."—(*Richmond and Skipton Chronicle.*)

[The indenture proves that Robert Clemesha was apprenticed to a gardener, and he may have held that office at Ribston Park, but what authority is there to show that he raised the Ribston Pippin? There are other claimants of the parentage of that excellent Apple. We quote the following from Dr. Hogg's "British Pomology:"—

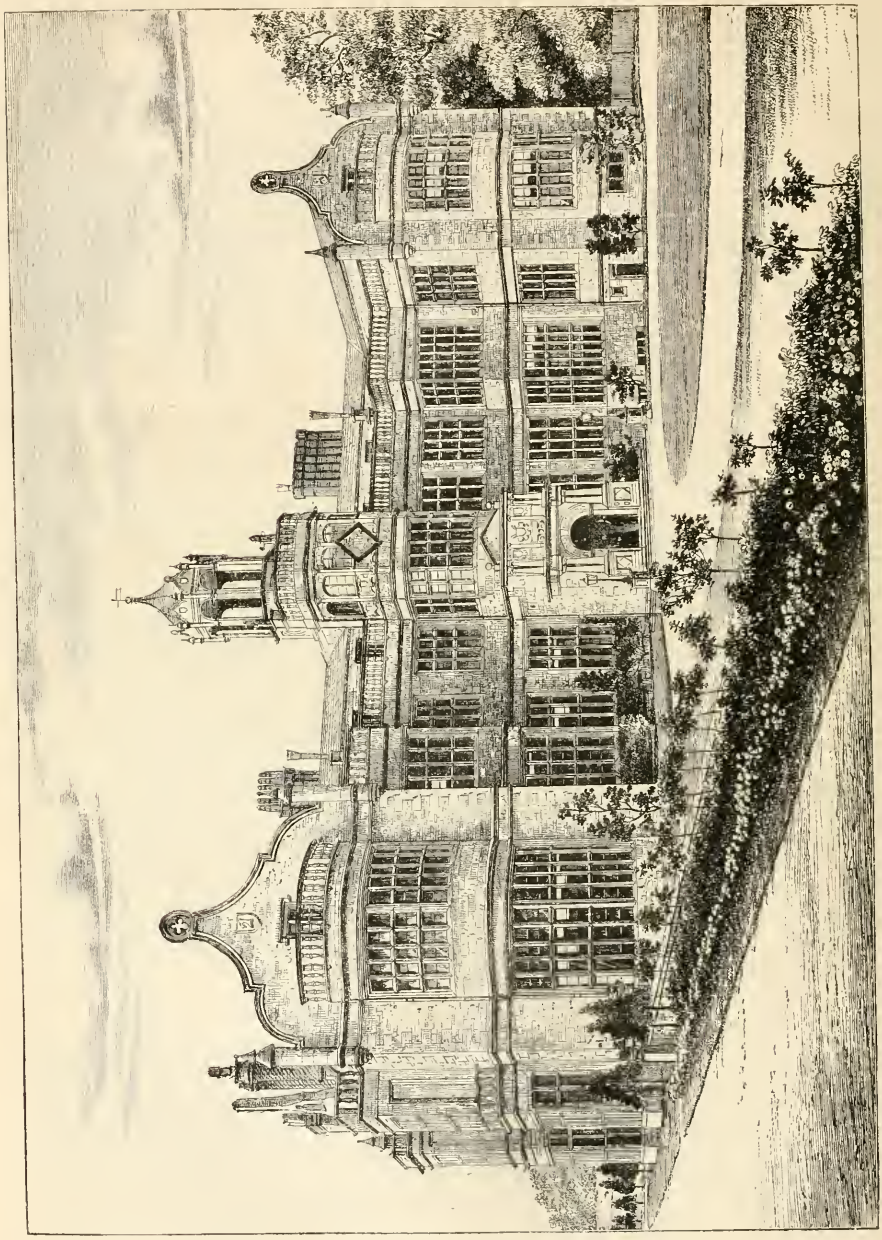
"It is not mentioned in any of the editions of 'Miller's Dictionary,' or by any other author of that period; neither was it grown in the Brompton Park Nursery in 1770. In 1785 I find it was grown to the extent of a quarter of a row, or about twenty-five plants; and as this supply seems to have sufficed for three years' demand, its merits must have been but little known. In 1788 it extended to one row, or about one hundred plants, and three years later to two rows; from 1791 it increased one row annually, till 1794, when it reached five rows. From these facts we may pretty well learn the rise and progress of its popularity. It is now [1851] in the same nursery cultivated to the extent of about twenty-five rows, or 2500 plants annually.

"The original tree was first discovered growing in the garden at Ribston Hall, near Knaresborough, but how, when, or by what means it came there, has not been satisfactorily ascertained. One account states that about the year 1688, some Apple pips were brought from Rouen, and sown at Ribston Hall, near Knaresborough; the trees then produced from them were planted in the park, and one turned out to be the variety in question. The original tree stood till 1810, when it was blown down by a violent gale of wind. It was afterwards supported by stakes in a horizontal position, and continued to produce fruit till it lingered and died in 1835. Since then a young shoot has been produced about 4 inches below the surface of the ground, which, with proper care, may become a tree, and thereby preserve the original of this favourite old dessert Apple. The gardener at Ribston Hall, by whom this Apple was raised, was the father of Lowe, who during the last century was the fruit-tree nurseryman at Hampton Wick."]

INGESTRIE HALL,

The Seat of the Earl of Shrewsbury.

Bright rapidly-flowing streams of water bear about them a charm to which the most stolid and careless observer cannot be altogether insensible; and as in these gross manufacturing days clear waters are rapidly becoming more rare, it is with a feeling of satisfaction that one first gazes upon the Trent in the neighbourhood of Ingestrie Hall. Rising in the highlands of the northern part of Staffordshire it passes through the county in nearly a south-easterly direction until it reaches Rugeley, where it turns more to the north-east, and enters the adjoining county of Derby. Shortly after leaving Stoke it enters the broad valley that bears its name. The Trent Valley is remarkable for the richness of its meadows, which in some places are barely elevated above the range of the floods, and therefore have very large breadths often submerged at the time when these prevail; in fact, the whole of the level land



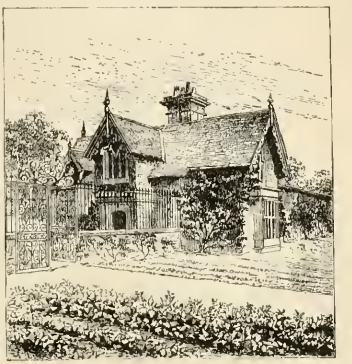
Ingrestrie Hall.

on both sides of the banks has no doubt arisen from an alluvial deposit, and it now forms some of the best land in the kingdom. The scenery, however, is neither bold nor varied, and the traveller in passing through it sees nothing near hand to vary to any considerable extent the tameness of the prospect, as the rising ground on each side is too far off to be seen to advantage. But if he were able to examine the country more leisurely he would see that there is much to admire, and would learn that a well-directed industry has been at work in times past as well as at the present. When "Domesday Book" was compiled in the year 1081, this Staffordshire district was justly known as *Gestreon*, the Anglo-Saxon for production and riches. The district was granted by William the Conqueror to his follower Robert de Tocin, a relative of, if not himself, the Royal standard-bearer of that name. The King conferred upon him, also, the great barony of Stafford, and Gestreon was a part of its vast domains. Probably by marriage and without intermediate possessors it passed to the Mutton family, Eudo de Mutton being Lord of Ingestrie, or Ingestren, as it was then called, in the reign of Henry II. Eudo gave lands in Ingestre to St. Thomas the Martyr Priory, then recently founded at Stafford, became one of its lay brothers, and left the remainder of his estates to his son, Sir Ralph de Mutton, whose daughter and sole heiress married to Sir Philip de Chetwynd. In the possession of their descendants it has ever since remained.

Ingestrie Hall is situated on the right bank of the Trent, nearly in the centre of the county, a few miles from the county town of Stafford, but nearer to the railway station Colwick. Its position is near the base of the sloping ground which forms the right bank of the valley, the mansion being somewhat elevated above the valley, though it is questionable if it would not have been better still higher up. The ground slopes away from it on the east and north sides, while it rises to the south. The approach is by the east, the offices are attached to the north side, and the dressed grounds surround both the others. On the western side is a large Italian garden, and to the south are the pleasure grounds, which rise gently until they blend in a wood. The kitchen garden is to the north of the offices; and in the same direction is the church of Ingestrie, which had its origin as far back as the time when most dwellings of importance had their chapel. The mansion is built in the Tudor style, a combination of brick and stone, the latter forming the window mullions and dressings, the other the body of the work. The interior of the house has undergone much alteration, but its noble exterior is perfectly in keeping with the ample proportions of its principal apartments, and the general comfort that reigns within. It is large and commodious throughout, and although ancient, both the stonework and brick seem to have stood the test of time much better than many more recent buildings.

The park, also, which surrounds this noble abode is of proportionate size, and well studded with noble trees. The rising ground on the southern edge is crowned with timber, but the view in that direction is restricted. Eastward, however, the eye can range over the beautiful valley of the Trent, overlooking Shugborough Hall, which, hidden by the surrounding trees, stands at but a short distance off. The offices, although adjoining the mansion, are, nevertheless, effectually screened by Limes and other trees. The more open lawn to the south of the mansion is dotted with choice Conifers, amongst which are some fine Deodars and one or two excellent Araucarias. We hardly expected to meet with such a fine specimen in the centre of England, as we did here, so many having succumbed to the hard frost of 1866–67 in the southern counties, but here it was, and in good condition too. There were also other Conifers, for which the gently sloping lawn, running up to where it joined the wood, afforded some good sites, whilst here and there a group of Rhododendrons presented themselves, consisting of huge bushes 10 and 12 feet high, and in the most luxuriant health. A wirework fence ran between the lawn and the wood to exclude game, but it did not become visible until you were close upon it, and the dressed grounds, therefore, appeared to merge gradually into the wild. Immediately adjoining the house is the Italian garden. The gardener's house* represents the period in which the mansion was built, and is remarkable for its simplicity and plainness. The beds were mostly straight, and all Box-edged, with gravel paths of ample width between. Each bed was planted with Geraniums, Petunias, and Verbenas, all of which were doing well, and showing signs of careful attention.

We now come to the kitchen garden, which is exceedingly well represented at Ingestric. It lies to the north of the offices, as well as of the main building and the church. This last is not a stone's throw from the house, and we had only time to glance at it on our way to the garden. The garden is large, nearly level, and subdivided by a number of excellent brick walls, the slips being surrounded with ornamental Yew hedges. The various breadths of Broccoli, Celery, Carrots, and the presence of other crops, attested the wants of a large family. One or two rows of dwarf-trained Pear trees were loaded with fruit in a most unusual manner, considering the adverse season, and a still more pleasing sight was a wall of great height covered with healthy Apricot trees well laden with fruit. In the glass



Gardener's Lodge, Ingestrie.

houses, however, a still greater surprise awaited us. Excellent Grapes in bunches as large as is generally seen at most shows, and with good-sized berries, formed the general produce of the Vines. On making some inquiries about them we found the following kinds were very good indeed:—

Madresfield Court.—Very fine black Grape, large in bunch and well coloured.

Alicante.—Some excellent examples, but at the time of our visit (mid-August) not quite ripe. We were told it kept well.

Barbarossa [Gros Guillaume].—A noble Grape in very large bunches, but we were told it did not colour well.

Trebbiano.—Large, white. As this has generally a large bunch, even where such as Alicante are only medium-sized, it might be expected to be good here, and such it was.

Muscat Hamburgh.—Also good and promising.

White Tokay.—Not by any means a well-known Grape, and one we should have passed by without taking any especial notice, but we were told it was an excellent keeper—a qualification in a white Grape not by any means to be disregarded.

Black Hamburgh were good, and present at every corner.

Of Grapes which had been tried and found wanting were Golden Champion, Royal Ascot, and Duchess of Buccleuch.

These fine Grapes were grown to a great extent in virgin loam, the fine turfy soil of the rich meadow around furnishing nearly all that is used for making Vine borders. Some that was being prepared to remake the Vine border then on hand showed the character of the mould at view. It is an open soil of a dark brown colour, sufficiently charged with sand to prevent its holding water, while the roots of the grass and other herbage have united it into so closely-interwoven a mass, that a piece 4 inches or more thick might be beaten some time ere it fell to pieces or yielded any of its finer particles. It would be hopeless to try to imitate such a soil by any artificial mixture. Here Nature has done it, but only after thousands of years. The sandstone rock which bounds the valley has by degrees become disintegrated, and the particles mixing with the other sediment of the river, have formed a substance which seems all that is required for growing good Grapes. It would be difficult to find better fruit; and although the soil had, no doubt, much to do with the result, it is at the same time fair to state that

* The illustrations which we give are from photographs by Mr. Lapworth, of Stafford.

cultivation had also done its part, for everything was in the best possible condition. There was healthy foliage, an absence of insects, and all the other requirements that tend to success. All the contents of the house—Peaches, Figs, and other fruits, showed the same masterly care, without which it is hopeless to look for success, even where such an important element towards it as good soil exists. Other things were also good, including some fine specimen plants of the popular show kinds, as well as Ferns; but there was not time to examine all. In passing we noticed the front of Mr. Phipp's cottage, which is conveniently placed in the garden, covered from the ground to the eaves with the flowers of a fine purple Clematis, which formed a perfect sheet of colour, and was so thick that there was scarcely space to lay one's hand. I do not know the variety, but it was either C. Jackmanii or one resembling it. I had never seen so fine a display before, but most, if not all, the plants in the garden presented the same luxuriant growth. Vegetable crops, as well as flower-beds and forest trees, alike exhibiting that vigour which is the best token that a good and generous soil with skilful cultivation were combined in the result. One of these alone could hardly have accomplished it, and that both were forthcoming at Ingestrie is due to the fortuitous circumstance of Nature supplying the one, and to Mr. Phipps's skill furnishing the other.—J. Robson.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Proceed with sowing all kinds of seeds as directed last week. The ground is in excellent order for planting and digging, which should be finished without delay. Top-dress the beds of *Asparagus*: take care not to injure the plants with the rake or fork. A little *Celery* or *Lettuce* seed may be sown over the beds. New plantations may be made. *Beet* may now be sown in drills a foot apart. Sow seed of the Early Cape *Broccoli* and Cauliflower Broccoli in a frame, to bring them on as much as possible; also sow some in open rich ground. Plant out the autumn-sown *Cabbage*; clear up the leaves, and weed beds left for Coleworts. Sow *Capsicums* on a hotbed. Stir the soil round *Cauliflowers* under hand-glasses, and earth them up; supply them with manure water. Prepare *Carrot*, *Onion*, and *Parsnip* ground, and sow a good breadth as soon as the soil is quite dry. Charred materials, or any old compost sown in the drills or on the bed, will bring the young plants on quicker. Follow up successional sowings of *Peas* and *Beans*. Occasionally water the early slopes of Horn *Carrots* and *Radishes* with tepid water, and cover them up while the sun is shining on them before 3 P.M. Plant the principal early crop of *Potatoes* while the ground continues in good working order. Place hillocks of old tan over *Sea-kale* crowns to blanch the shoots.

FRUIT GARDEN.

Protect the blossoms of Apricots, Peaches, and Nectarines. Straw ropes, mats, canvas, bunting, fir boughs, and fronds of Ferns are all useful for this purpose. As soon as you have finished nailing the Peach trees mix sulphur and soap water to the thickness of paint, and draw a band of the mixture between the shoots in all directions; this once done, and that well, will secure the trees thoroughly from red spider for twelve months. Proceed with grafting, following in the order in which the buds break. Strawberries may still be moved, if with balls, and well watered in.

FLOWER GARDEN.

Attend to the top-dressing and pruning of Roses. Prepare a scheme of planting the beds in the flower garden, and estimate the number of plants required, in order to propagate stock without delay. Dress, where bulbs are coming through, with care, and plant out autumn-sown annuals. Those who plant old roots of Dahlias—they are superior to young cuttings for general display, if properly staked out—may put them in shortly, soiling them over 4 inches deep to secure them from frost. Plant Lily of the Valley where requisite. Plant out Pansies and Carnations, sow Wind Anemone for autumn flowering, and attend carefully to the sowing of showy annuals, placing inverted pots over the patches, if the species or variety is shy or liable to be devoured. Do not forget Mignonette and Sweet Peas. Roll lawns. The pans or boxes in which Ranunculus seed is sown should be protected from excessive rain and frost. A cool frame is the best situation for them until they are well up. The best beds should be planted without delay, taking advantage of the first favourable opportunity; avoid wet weather. Pinks, when intended to be grown in pots, may be put in half-pecks as soon as convenient. I would advise florists generally to give this system a trial; when intended for exhibition they will be found much more convenient to shade or bring forward as circumstances may require. Should canker appear in the collection of Tulips, immediate attention must be paid to them, removing the soil from the diseased parts, and cutting over as occasion may require. Cover on frosty nights, and if possible do not let water lodge in the hearts of the plants. Auriculas and Polyanthuses in frames will require a more regular supply of water. Top-dress with rich soil if not previously done, but liquid manure not too strong will be found far better.

GREENHOUSE AND CONSERVATORY.

Potting must forthwith commence, and be continued with scarcely any interruption until next October, indeed it may be said never to totally cease. Those who have not secured the necessary compost under cover should do so immediately. March offers many opportunities for housing turfy or other composts in a mellow state. Remember that there is, and can be, no period assigned for a general shifting, although such ideas prevailed in former days. Forty years ago the man who did not top-dress all his greenhouse plants in the course of February was considered a great sloven; now, however, there is much less of this top-dressing, and plants are shifted by good cultivators according to their habits and the purpose for which they are intended. Let me here point out what appear to be frequent erroneous practices—namely, overpotting, or potting in composts that are too rich, plants which naturally run too much to leaf. It is obvious that such plants as Veronica speciosa will not bear the application of such stimulating composts as Thunbergia alata, nor should they be suddenly indulged with liberal pot room. The plant would indeed be covered with the most luxuriant foliage, but the blossoms would be few, and produced late in the season. For plants of such gross habit simple loamy soils will in general be found quite rich enough without the addition of vegetable matters. Manures are quite out of the question. The Camellias intended for flowering late in the autumn should now be forced into wood under a temperature of from 60° to 65°. Shade is necessary while they are making their young wood. Those exhausted with flowering should be cut back and removed to a cool greenhouse for three weeks, giving them a little liquid manure. The same practice may be adopted with the Indian Azaleas. If forced into wood now they will bloom in the course of November and December. The Citrus tribe may be pushed forward in bottom heat where size is an object; if any are sickly and in a bad state at the roots, cut them back, disroot them, washing the roots, and place them in smaller pots, using turfy loam, leaf soil, sand, and charcoal, afterwards plunging them in bottom heat in a moist atmosphere. See to regularly shifting Cinerarias, Pelargoniums, Calceolarias, and Fuchsias. Propagate plants for the flower garden. Root-propagation may be resorted to with plants in a dormant state. Sow exotic seeds, and cover each pot with sphagnum. Make cuttings of the various Begonias for flowering during next November and December. Do not forget B. incarnata and B. manicata. Stop gross and barren shoots on the hybrid Roses in pots. Introduce Camellia stocks into heat, if they are to be grafted or inarched on the new wood when firm.

STOVE.

Endeavour to separate the Orchid tribe at this period as much as possible. If there is only one house, keep one end cooler by a free circulation of air, and by placing such as the Lælias and Cattleyas at the cooler end, and the true Air plants and Dendrobiums at the warmer end. Stanhopeas, Gongoras, &c., suspended in baskets should soon have a thorough watering. They will bloom safer and later, however, if kept dry another fortnight, maintaining much humidity in the atmosphere, whilst circulation of air can be obtained. The Hippeastrum and Amaryllis will now be flowering and will require rather liberal waterings, and some will soon need shifting; see that their leaves are preserved from injury. The Clerodendrons may be disrooted and plunged in bottom heat, and all exhausted winter-flowering plants should be served in a similar way.

COLD PITS OR FRAMES.

One of these structures should be fitted-up with sashes for the reception of the thinnings of the greenhouse. Many hard-wooded plants may be moved thither, and the lights protected with mats at night. This will make way for the increasing size and number of the Fuchsias, Cinerarias, Verbenas, and

Calceolarias, together with the cull of the flower-forcing pit.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Owing to the wet state of the ground we could do little beyond keeping the walks neat. The weather has been so mild, although on one or two mornings glass and mats freely exposed have been slightly crusted, that we have given more air than usual to such vegetables as Potatoes and Radishes in frames and pits.

Frames versus *Pits*.—For safety from such vermin as rats we prefer pits, as with sound wall-plates there is no danger of intruders at night, whilst into small hotbeds covered with frames they easily make their way. As regards vermin, then, pits are to be preferred to frames, but if a temporary hotbed is made in them there must be head-room for the plants, and often seedlings of others coming through the ground must, as a consequence, be too far from the glass in dull wintry weather. Therefore, except for safety from vermin, for early Potatoes, Radishes, Carrots, Turnips, and similar crops, we prefer a slight hotbed covered with sashes, as the plants, from being nearer the light, are more robust in growth than those farther from the glass, and as they grow the sashes can be raised from time to time. The easiest way to do this is to put a piece of wood under each corner of the frame, say 15 inches in length, 8 inches in width, and 1 inch in depth, level and askew at each corner, and on each piece to place as may be needed one, two, or more bricks. Of course the soil must be secured inside round the sides of the frame.

Even with *Potatoes* this raising of the frame will be less required if, after the shoots are 9 inches or a foot in length, the terminal bud of the shoot be picked out with the point of a small knife. This keeps the shoots shorter and bushier, and does not affect the early tubering, so far as our experience goes. It is quite different if you stop the shoots of such Potatoes by removing 2 or more inches of the top, as you would top Beans in bloom to cause them to set more freely. Such topping of Potatoes, according to our experience, always acts injuriously on the crop. The mere nipping-out of the terminal bud arrests elongation, and gives no unpleasant check to the plant.

FRUIT GARDEN.

We have not yet quite finished pruning and washing out of doors; nailing has yet to be done.

Planting must now be completed as soon as possible, and if properly done will often prove more successful than that performed in the middle of winter. The end of October and beginning of November may be considered the best times for planting fruit trees in general, as the ground is then warm enough to encourage early rooting. After it has been once cooled we have often found, in planting of fruit and forest trees, that the success was rather greater in March than in January and February, the reason, no doubt, being that as the warmth of the advancing spring told upon the buds, their swelling and expansion also reciprocally affected the roots. Merely as an evidence of the mildness of the season we may mention that a large Horse Chestnut tree, transplanted a month ago, is breaking freely into leaf. We are afraid of this fine tree being killed if we have a sharp frost. If in an ordinary season, the buds had expanded six weeks or more later, we should have felt sure that the roots would have met the wants of the expanding leaves.

Protecting and Retarding.—A little frost would greatly help fruit trees out of doors by keeping them back. If this weather continue, a little protection should be in readiness. If a sharp frost come at the end of the month, Currants, Gooseberries, and Raspberries may be saved by sprinkling over them rough hay or dry litter. Whitening them with limewash now, or earlier, will help to retard them. Apricots, Peaches, Plums, &c., against walls, that often do well without any protection, especially if the weather is dry, though a little frosty, will most likely need some protection this season, as the buds are so forward. Though we have none, yet on the whole for protecting purposes nothing is better than calico sheeting, easily moved by pulleys and rings. One reason why it is the best protector is because it is the best retarder. If we had it we would use it every sunny day to retard the blooms before they opened, and leave the trees fully exposed in dull days and all night, unless there should be a frost severe enough to injure the buds before they were fully expanded. When the bloom opens the practice must be reversed, so as to give the bloom all the sunshine possible. We feel sure that the retarding principle has not been sufficiently acted on as respects our finer fruits. Another object is also secured by the sheeting, if it is at all strained and kept 18 to 24 inches from the wall—namely, keeping the blooms dry. Then, again, the soil becomes heated, whilst the wall can be kept cool, before the bloom opens, and there is, therefore, a better reciprocal influence between the roots and branches.

For protection we have used almost everything that has been tried—broom, spruce, evergreens, beech twigs, common netting, woollen netting, fine Nottingham lace netting, and next to sheeting we should prefer the last, used as a fixture, as it lets plenty of light through, retards a little, and in wet weather the wet trickles down from top to bottom. All these modes involve so much trouble, and expense too, that we feel convinced by far the most economical way in the end for Peaches, Apricots, &c., would be to face the wall with glass in the orchard-house style. Instead of having a narrow house with upright glass we should prefer a lean-to from 10 to 12 feet in width, and then there is so much more valuable room enclosed.

Orchard Houses.—As far as can be done with safety as respects wind, we keep these open night and day so as to retard the trees as much as possible. Little more excitement would cause the buds to burst. If we have a very bright sun for several days we shall be tempted to shade the roof with a sprinkling all over of whitened water from a syringe. It is just possible that we may not have much more frost, but it is also possible that we may have sharp nights at the end of March, and even in April. In unheated houses we should then have no help but the calm air in a shut-up house. Where such houses are furnished with hot-water pipes or flue we may take the natural advantage of the forwardness of the season, as the means of heating will keep all safe.

We gave about a quart of water to each pot fruit tree, and will follow shortly with more. It is bad policy to allow the roots to become too dry while the buds swell, as they might drop.

Repotting Fruit Trees.—On this subject we have many inquiries, and to all, whether the trees in pots are at home, or have to be received from the tree merchant, we give one reply—Do not repot if you wish to have a crop of fruit. If the pot is small make the hole in the bottom larger, plunge the pot less or more, put a rim round it for rich top-dressing, and defer repotting until the fruit is gathered. If, nevertheless, repotting is resolved on, the soil round the ball cannot be made firm, but even then you must not be too sanguine as to results.

The same principle applies to pyramid trees taken up out of the ground; it is too late in this forward season to pot and expect a good crop if the trees have ordinary treatment. We have several times succeeded by potting in March, when the season was not so forward as this. The roots were placed in pots as small as would hold them, and the soil packed firm. The pots were plunged over their rims in a mild hotbed out of doors, ranging from 65° to 70°. The tops of the trees were fully exposed, only shaded from bright sunshine. By the time the flower-buds expanded the bed had cooled down, but the object aimed at had previously been attained—namely, the formation of fresh roots to meet the wants of the swelling and opening buds. If such plants had been potted in October they would have required much less trouble and care. Frequently we must make the best of unfavourable circumstances. —R. F.

TRADE CATALOGUE RECEIVED.

Daniels Brothers, Eaton, Norwich.—*Illustrated Seed Catalogue and Amateurs' Guide.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Books (*J. A. K.*).—The "Cottage Gardeners' Dictionary," and Keane's "In-door Gardening," and Keane's "Out-door Gardening" would give all the information you require. They can be had post free from our office, the Dictionary for 7*s.* 2*d.*, and the other two for 1*s.* 7½*d.* each. (*Miss B. D.*).—We do not publish either of the works you name, nor do we know them.

SIZE OF GRAPES (*J. Fletcher*).—We believe that Grapes are grown to a size never attained forty years since. We have recently seen berries of the Lady Downe's variety that no Grape could exceed.

SOOT AS A TOP-DRESSING (*L. M. N.*).—It would no doubt benefit your heavy-soiled meadows. As moss is inclined to grow on them, we should harrow them with a light harrow after sowing the soot. Apply it during showery weather, and if you sow with your grass seeds some of the dwarf Trifoliums, these will help to exclude the moss.

SEA-KALE CUTTING (*R. H.*).—Cut the shoots once, and do not excite them by heat to produce shoots for another cutting the same season. On the shoots being cut, gradually remove the heating material. You need not discontinue cutting until all the shoots have been cut once. The Sea-kale season lasts from November to May. The plants must make a good growth during the summer.

PRUNING NEWLY-PLANTED PEAR TREES (*A Constant Reader*).—We presume your trees are trained horizontally, in which case they will have shoots or branches on opposite sides of the stem at 9 inches or a foot apart. These or branches on opposite sides of the stem at 9 inches or a foot apart. These side shoots should be trained in at their full length, without cutting off even their points; but any shoots along them, except the short stubby shoots or spurs, should be shortened to within half an inch of their origin. Beside these side shoots or branches, the trees will have leaders; cut back the leader of each tree to 12 inches of last year's wood—two years old—and this will give you three shoots or more, but reduce the number to three. Train one as a leader, the other two as side shoots on opposite sides of the stem, and 1 foot from those next below. If the trees are "maidens" cut back to 12 inches.

PASSION-FLOWER SHOOTS DYING (*C. H. C.*).—The shoots were much mildewed, but we are not sure that mildew was the cause of their dying-off so suddenly. We find those with angular and not round shoots are very liable to be attacked by a fungus and die-off if there is drip from the roof. See to be attacked by a fungus and die-off if there is drip from the roof. that no drip falls on the stems or young shoots, give the plants perfect rest in winter, encourage growth when you can command a good brisk heat, and accompany it with plenty of air.

EARLY VIOLETS—CHILIAN BEET—SHRUBS FOR SWAMP (*Tipperary*).—The best Violets for early bloom are Russian and Czar, the latter best of all. Chilian Beet for the flower garden is best sown at the beginning of April in pans placed in very gentle heat. When the seedlings appear place them near the glass, give plenty of air, and plant them out in moist weather at the close of May. The following will suit you—viz., Cornus sanguinea, Viburnum Opulus and its variety nanum, Deutzia scabra, Willow, Birch, and Alder. The last three are trees.

STEPHANOTIS FOR GREENHOUSE—VINES PLANTING—ACCUBA POLLEN (*A Subscriber*).—Stephanotis floribunda would not succeed in a greenhouse, but it would do so in a warm vinery. In planting Vines it is not a good plan to layer a portion of the cane in the soil, but you must spread out the roots, cover them with from 3 to 6 inches of soil, keeping the setting-on of the roots just level with the surface, and cover the roots at that part 3 inches deep. The best time to plant is after they have begun to grow an inch or two. Collect the Aucuba pollen when quite dry, and fold it up in sheets of writing paper. It will keep for a long time, or until the female plants flower. Four Strawberries for an orchard house are President, Sir Joseph Paxton, Premier, and Dr. Hogg, or Cockscomb.

SEA-KALE AFTER FORCING (*A. B.*).—When you have cut all the shoots, plant the roots 12 by 15 inches apart in rich soil in an open situation; in planting surround each root with a little sand or very fine ashes. Supply liquid manure liberally from the middle of May to August. Strength will thus be secured for forcing in the cellar next winter, but we should only take up half the roots, allowing the others to remain, with the view of covering them with pots and litter in March, not so as to heat, but to exclude light. The roots in the cellar will produce a crop for early use, and those in the open ground will afford a succession. The latter we should take up in the following year, allowing those planted out from the cellar to remain, and thus only take up in alternate years. In this way the roots will be strong, but if you take up every year they will become weak. The position will suit Cabbage plants, but not nearly so well as one having the sun on it all day. Why have a frame for forcing Cabbages? It is quite unnecessary.

SELAGINELLAS IN WARDIAN CASE (*Mechanic*).—It is remarkable that they do not succeed where Ferns thrive so well. We think the failure arises from the dryness of the soil during the winter. You might succeed better if you were to replant in August, for in some cases they become drawn, and then when the soil or atmosphere becomes drier they perish. As you succeed so well with Ferns, do not spoil them for the sake of the Mosses.

ACER NEGUNDO FRAXINIFOLIUM PROPAGATION (*W. S.*).—In November or early in spring you may make cuttings of the ripe wood, 10 inches long, and insert them two-thirds of their length in rather light soil in a sheltered situation out of doors; but it is best propagated by grafting or budding on Acer platanoides or A. campestre. The best plants are obtained from seed.

PAVETTA BORBONICA (*G. B.*).—It is difficult to strike: the easiest way to do so is to make cuttings of the half-ripened shoots with a firm base, and insert them singly in small pots in sandy peat and loam. Surround the base of the cutting with silver sand, place the pot within one of a larger size, cover with a bell-glass, and set the pots in a bottom heat of 75 to 80. Keep the soil no more than moist, and shade from bright sun. We cannot say whether any benefit arises from a heel.

CRYSTALS OF AMMONIA (*E. W. B.*).—Crystals of which of the salts of ammonia? Half an ounce of them to a bucketful of water will be ample of any of the salts to make a liquid manure for potted plants. To flowering plants it should not be applied until the flower-buds are developed.

CLIMBING ROSE IN DRY SITUATION (*J. S. K.*).—A stone slab placed over the roots of a Rose would keep the ground dry and healthy in long-continued wet weather, and moist in dry weather. Moreover, the stone when heated by the sun would protect the ground. Such a Rose as the Cloth of Gold likes heat with an adequate proportion of moisture. "J. S. K." would be more likely to succeed with Marechal Niel. The Cloth of Gold is very tender, and especially so at the tops of its flowering shoots. The severe hoar frost in the spring — it is a very early Rose—would perhaps destroy all the buds; and, as it is a shy bloomer, there may be no second series. I have two beautiful plants of Rose d'Or on my south frontage. It is choice and distinct as to form and colour. In colour it is pure yellow with a coppery centre. I have never bloomed it, but blooms were sent to me. The plants are breaking finely. Roses are forward here (Dorset). I see a fat bud of "old Gloire" and a few others.—W. F. RADCLYFFE.

PEACH HOUSE AND CUCUMBER HOUSE (*T. B. W.*).—From the plan and description given, we cannot be sure of the reasons why the water in the Cucumber house will not heat. We would draw your attention to the following points. First, Where is your supply-cistern placed? If that communicates with the bottom of the boiler at once all the better. Is that cistern sufficiently elevated to be 2 or 3 feet higher than the highest pipe in the Cucumber house? Secondly, Do your return-pipes go near the bottom of the boiler? Thirdly, Are the 20-feet flow and 20-feet return 2-inch pipes connecting the boiler with the Cucumber house right as to level? They should not dip at all, nor should they be lower than the pipes in the Peach house. If these rise a little to the Cucumber house all the better. Fourthly, Even with this care, if there is no stopcock on the flow for the upper pipes in the Cucumber house, we should expect them to heat more than the pipe on the lower level for bottom heat. It is well to be able to give bottom heat and top heat independently of each other. Fifthly, If the pipes rise as you state, and there is no intermediate dip to speak of, and the supply-cistern properly placed, then we should come to the conclusion that the want of circulation is owing to the presence of confined air in the pipes; and the best way to avoid that if present, and not always at the highest point, is to keep the supply-cistern filled, and allow your expansion-pipes to run for some hours, or for half an hour at a time, until the water is changed. The snapping and cracking you refer to in the pipes, also the overheating of the supply-cistern, almost convince us that that is the cause. If even in these 2-inch supply-pipes you have 2 inches of compressed air, the heated water cannot pass before it is dislodged. See what was stated in "Doings of the Week" last week as to heating a Cucumber house. With all going right your piping will not be sufficient for winter Cucumbers. It will do from March to November, or so.

UNTIDY KITCHEN GARDENING.—"Is a gardener to be blamed if he allows decayed vegetable leaves, as Scotch Kale, Brussels Sprouts, &c., to pollute the air of the kitchen garden?" We say, Decidedly he is to be blamed if he can find time and labour to remove all such nuisances, and does not do so. If there is time to attend to all such matters, and that attention is not given, we would find a remedy; but cases have come under our notice where the gardener, to keep things neat, ought to be hard at work for sixteen out of the twenty-four hours, and with that we have no sympathy.

LETTING GARDEN, &c. (*F. P. G.*).—This matter we can scarcely enter into. The terms seem easy enough for the gardening tenant, but then much depends on the market to be obtained. We have known gardeners decline to take a large walled garden in the country for keeping it in good order, and then pay a high price for land near London. That was before cabbage became so common, but even they add to the cost, and so on make a rental. We hope all will go well, and cannot but admire your anxiety that the gardener should thrive and not lose by his bargain. The difficulties ahead will be when more than one day a-week is wanted for the flower garden and pleasure ground, and we presume there is a vinery, a greenhouse, and a conservatory, of which nothing is said, but which will require some daily attention.

SOOLY-QUA CUCUMBER (*Elston*).—It is thus described in the "Gardeners' Year-Book" for 1871—"A new Chinese Cucumber. A species of Cucurbitaceæ (most probably belonging to the Luffa section), producing fruits of enormous size, being between 5 and 6 feet long, and 18 inches in circumference, resembling huge Cucumbers. Received from Foochou, where it is grown and eaten by the natives in the green state, boiled with rice, &c."

FLOWER-GARDEN PLAN (*W. G.*).—On the system adopted, the planting is very good. We are doubtful if your four 3's would not be better crossed, and the four 2's be crossed—that is, one pair of one arrangement instead of two pairs. Then, again, the beds being sunk, and coming thus more fully under the view of the windows, perhaps the double-pairing of each, as it would be more simple, may strike the eye most. If you adopt the proposed plan, then, though the centre, Centaurea edged with Dell's Beet, would look well, we should prefer the Iresine Lindeni, or even Perilla to the Beet, though the one at a distance would look as well as the other. Then for the four 3's, we think Acheranthum Roseb will be too lofty, and, therefore, lose the unity of the design as to height. As you have Indian Yellow, that would be better, or such scarlets as Vesuvius or Emily Moreland, and as you have Madame Vaucher, we would edge with that. Then the four 3's would do, purple Verbena edged with Pyrethrum. 4, 4, Will do, but the Calceolaria should be low, as Andrew Florihunda. 5, 5, Plant as stated, Christine, and edge with Waltham Seedling, purple Verbena, or Iresine. 6, We would change, and have white-flowered Geraniums, or Bijou Geraniums, edged with dwarf Ageratum. 7, 7, 7, 7, As stated. 8, 8, As the beds are large, we fear the Gazania would cause them to look flat unless it were raised. As you have it we would prefer Waltham Seedling for a centre, and Golden Pelargonium round it, with an edging, if deemed necessary, of Lobelia speciosa. 9, Scarlet Geranium; but if they are low-growing, as they should be in such a composition, and unless the plants of Centaurea are small, we should prefer a good edging of the Koniga maritima or variegated Alyssum.

COVENT GARDEN MEASURES (*S. B.*).—The following extract from our 'Gardeners' Year-Book' gives all the information you ask for—"These being often made either of osier or deal shavings, vary tridingly in size more than measures made of less flexible materials. *Sea-kale Punnets.*—8 inches diameter at the top, and 7½ inches at the bottom, and 3 inches deep. *Radish Punnets.*—8 inches diameter, and 1 inch deep, if to hold six bunches; or 9 inches by 1 inch if to hold nine bunches. *Mushroom Punnets.*—7 inches by 1 inch. *Salading Punnets.*—5 inches by 3½ inches. *Half Sieve.*—Contains 3½ imperial gallons. It averages 12½ inches in diameter, and 6 inches in depth. *Sieve.*—Contains seven imperial gallons. Diameter 15 inches, depth 8 inches. A sieve of Peas is equal to one bushel; a sieve of Currants twenty quarts. *Bushel Sieve.*—Ten and a half imperial gallons. Diameter at top 17½ inches, at bottom 17 inches; depth 11½ inches. *Bushel Basket*—Ought when heaped to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of a pottle of Mushrooms should weigh 1 lbs. *Hand*—Applies to a bunch of Radishes, which contains from twelve to thirty or more according to the season. Radishes, which contains from twelve to thirty or more according to the season. *Bundle*—Contains six to twenty heads of Broccoli, Celery, &c.; Sea-kale, twelve to eighteen heads; Rhubarb, twenty to thirty stems, according to size; and of Asparagus from 100 to 125. *Bunch*—Is applied to herbs, &c., and varies much in size according to the season. A bunch of Turnips is twenty to twenty-five; of Carrots thirty-six to forty; of greens as many as can be tied together by the roots. Grapes are put up in 2 lbs. and 4 lbs. punnets. New Potatoes, by the London growers, in 2 lbs. punnets. Apples and Pears are

put up in bushels, sieves, or half sieves. A hundredweight of Kentish Filberts is 104 lbs. Weights are always 16 ozs. to the pound."

FRUIT TREES FOR NORTH WALL (*Glerum*).—There are none that will succeed except the Morello Cherry and the Red Currant.

POISONING CRICKETS (*Constant Reader*).—If the druggist will not sell you arsenic, we cannot help you in that direction. Chase's beetle and cricket poison is sold by all chemists.

BURNING CLAYEY SOIL (*Cheriton*).—We shall reprint an article on the subject next week.

EUCHARIS AMAZONICA CULTURE (*E. B. C.*).—Pot the plants and place them in a bottom heat of 70° to 75°. Encourage them with heat and moisture, and when growth begins to cease withdraw the pots from the bottom heat, place in the full sun, give plenty of air, and only sufficient water to prevent the leaves from flagging. The atmosphere should be dry, the night temperature 60° to 65°. At this stage a vinery would be a suitable structure. After a six or eight-weeks rest return the plants to bottom heat, and they will probably throw up flower-scapes. Continue the plants in a good heat, with plenty of moisture until October, then keep them dry, and in a temperature of 55°. After February give bottom heat.

EAST LOTHIAN STOCKS—VARIOUS (*F. J.*).—Plant out the Stocks sown last autumn and wintered in boxes, in rich light soil in a sheltered situation. Protect them in frosty weather. Plant a foot apart every way. They will flower in June, and continue a long time in bloom, but are at their best for a month to six weeks. They are very fine varieties. The bedding plants you have had plunged in sawdust in a cold frame, we should now set on a hard floor, removing them from the sawdust. We should not water the plants overhead until the beginning of April. It is not advisable to coat the glass with whitening and milk, as your doing so would keep out both light and heat, of which you cannot command too much. The propagating frame would be all the better of the glass being whitened; indeed, if the weather is bright cuttings must have shade.

GRAFTING VINES (*Barry*).—Vines can be grafted readily if the operation is performed at the right time. It should be done when the young shoots have grown 3 or 4 inches. The canes which are to be worked should be cut back before there is any danger of bleeding. Ordinary whip-grafting is the best method, and the scion should be put on opposite to the young shoot, which should be allowed to remain to draw up the sap. The graft should be clayed in the usual way. As soon as the scion commences to push, all other buds and shoots should be removed. Inarching is by far the safest method. You should train up a young rod from the base of the stock, and one from a pot plant of the variety you intend to introduce, grow both together until they are 4 feet in length, then cut a slice 3 or 4 inches in length from the side of each, cutting in to the pith. Place the two wounds together, and tie firmly with soft matting. In three weeks the ties must be slackened, but not entirely removed until the end of the season. Budding may also be performed in autumn with much success. The Vine eye must be prepared as in ordinary budding, except that a portion of the wood must be allowed to remain; a corresponding notch is cut on the young wood of the Vine intended as a stock, the bud is neatly fitted-in and tied with matting, dressing it with Mastic l'Homme Lefort. We have performed this operation successfully as late as October 17th, and the buds were sent a distance of four hundred miles.

DWARF POINSETTIAS AND EUPHORBIAS (*S. T.*).—Plant eyes of the Poinsettia now in a good top and bottom heat of from 70° to 75°; stop the shoots which spring from these until July, then take off the tops and put them in the ground. By this means you will obtain good plants for winter flowering. The Euphorbia may be treated in the same way, but the shoots should not be stopped after June. Rhynchospermum jasminoides must be grown in a greenhouse. It should be placed in a compost consisting of two parts fibrous loam, one of sandy peat, one of leaf soil, and a sixth part of silver sand. The pot should have be well drained, and the plant inserted firmly. When it becomes necessary to give it a shift, do so, but let it be a moderate one. Water it carefully when not growing, but when this is the case do so freely. It should have an airy position, and be supported as it developes. Bottom heat is not essential for its welfare. It is a very pretty, white, sweet-scented, climbing evergreen.

MARÉCHAL NIEL ROSE WITH FLOWER-BUDS (*J. M.*). — We presume the buds are what were formed in the autumn of last year, and if so the prospect of their developing is not great, though they may do so if the spring be mild. We should advise you to prune them moderately now, removing the weak and unripe wood, and cutting back the shoots to firm wood; should the buds expand they will give very poor flowers.

KING OF TOM THUMB NASTURTIUM (*Idem*).—The change of colour in the flowers was no doubt caused by the wet and want of sun which prevailed last autumn. For good colouring, bright weather is necessary. The fact of the seed having a tendency to change colour will not affect the colour of the flowers on the plant arising from it.

CELERY FOR MARKET (*W. C.*).—Sandringham White is a good sort, not liable to run, and attains a good size; Seeley's Leviathan White is larger, and good; and Ivery's Nonsuch is a most excellent red or pink Celery. These will suit you.

CAMELLIA BUDS NOT OPENING (*Joseph Smith*).—The cause of the bud you sent us not expanding is either due to the atmosphere being too cold and moist, or to the plant making weak growths, and having too many buds. Thin out the buds, leaving no more than one on the strongest shoot, and none at all on the weakest. When they begin to swell give the plants a temperature of 45° to 50°, and admit air freely. Judging from the flower we should say it was Mathotiana alba, a beautiful white variety with a very large flower.

SEA-KALE ROOTS DECAYING (*A. G.*).—We think the decay of the roots is due to their being planted among ashes in the tin over the tank heated by the hot water. Plant the roots in light sandy soil kept just moist, in a temperature of 52° to 58°. The shoots will come freely without the bottom heat from the lamp, which is wholly unnecessary, and, along with the ashes, probably the cause of the roots decaying.

NAME OF FRUIT (*Pomona*).—Golden Winter Pearmain.

NAMES OF PLANTS (*G. S. Betts*).—Pteris cretica albo-lineata. (*J. G.*).—1, Sedum aizoideum variegatum; 2, S. Sieboldii, Johis aureis variegatis; 3, Saxifraga Aizoon; 4, Primula denticulata; 5, Convolvulus mauritanicus. (*R. H.*).—1, Thujopsis dolabrata; 2, Retinospora pisifera; 3 and 4 are decidedly the same plant in different conditions, and is Juniperus excelsa. (*East Sussex*).—1, Phajus grandifolius, formerly more frequently known as Bletia Tankervillea; 2, An Eria, apparently E. bambusæfolia, or very near to it; 3, A hybrid from Rhododendron arboreum. (*F. Fowler*).—1, Aponogeton distachyon; 2, Melia Azedarach. Not native of Brazil, though no doubt cultivated there, as it is in most tropical climates, as a garden plant. It is native of the East Indies, and is frequently called the "Pride of China," or the "Pride of India."

POULTRY, BEE, AND PIGEON CHRONICLE.

EXHIBITING FOWLS.

SHOULD a bird on its return from a show be taken ill and die, it is unfair to put all the blame on the committee's want of proper attention. I think owners have quite as much to answer for, and in many cases more, than those gentlemen who undertake the management and responsibilities of our shows, the duties of which are very onerous and generally thankless.

But let us see how birds are treated while at home and at exhibitions. After the selection of the bird that is to win honour and fame for its owner, or, it may be, to sink from being pampered and overfed to a common dunghill cock, he is "put up," for two or three weeks before the day fixed for the show, in a quiet, warm, clean place, and there subjected to a course of training. He is first physicked if necessary, then carefully and regularly fed with the very best kinds of foods, and every dainty is offered to induce him to eat and increase in size—in fact, no expense nor trouble is spared to bring the bird to the highest possible state of condition. Stimulants are often given, even to a new-laid egg in a little sherry, and to make it of a proper consistence it is mixed with barleymeal. If, however, he feels indisposed to eat he is gently taken in hand two or three times a-day, the beak opened, and food put into his mouth, and worked down the throat, no matter if he dislikes the operation. At the expiration of the specified time he is considered to be thoroughly wound-up to the required state of perfection, and is sent away; perhaps he may have to travel a distance of several hundred miles. On the journey he is nearly suffocated in a luggage van. Arriving at the railway station he may have to wait there a few hours, and finally before reaching his destination, should his journey be in winter, he will be frozen on the outside of a van. And how is he treated while at the show? Instead of quietude and a well-known roosting place he finds him s f thrust into a wire pen with hardly enough room for him to turn round. He sees hundreds of other fowls in the same position as himself, all crowing, cackling, and excited. Everything is fresh to the bird; crowds of people continually pass and repass, and poke at him from early morning till five or six hours after his usual hour of going to rest, and this is repeated for several days, till at the end of the show the bird is quite worn-out from want of that rest and quietness so essential for the proper health of all kinds of poultry. His food during this time has been very different from what it was when he was at home. In place of those dainties and tit bits he has been so used to, he has had nothing but corn (too often very bad) and barleymeal mixed with cold water, which frequently produces that looseness of the bowels we so continually find birds suffering from while at shows. What with the excitement, change of home, food, and late hours, who can be surprised at birds returning to their owners in a state of illness, which frequently proves fatal? The only wonder to me is that so many birds stand exhibiting so continuously.

At some future time I may give my views on the treatment of birds while at shows, how to manage them on their return, and the injurious effects exhibitions have upon birds for breeding purposes.—W. J. NICHOLS.

POLANDS—CLASSES, CRESTS, &c.

I HAVE read with much interest Mr. Boothby's remarks upon our Polish classes, and, as he observes, not until we have separate classes for each variety, and adult and chicken classes, will justice be done to them. Of course, at small shows a chicken class could hardly be expected, but I certainly think there ought to be a separate class for each variety of Spangled, Gold and Silver, and an Any variety class for the others at the smaller shows.

Polish, especially Golden, are very much more numerous now than formerly. Four years ago, when I commenced with them, scarcely anyone in Sussex knew what they were, now there are more than twenty breeders within a radius of twenty miles. I do not exhibit much, for this reason—I find all kinds competing together. One judge prefers one kind, and another judge another kind, and so on.

Again, colour and markings, which, according to the "Standard of Excellence," are essential points, are too often quite left out; shape of crest, too, does not seem to be studied as it ought to be. I have seen badly-shaped large crests, birds with inferior colour and markings, stand before good-shaped crests of fair size, good colour and markings. We cannot study shape too much. I do not see why birds should be encouraged that have crests hanging too far over in front. What looks worse than a crest hanging down in front, wet and dirty? for instance,

the first-prize pair at Portsmouth; I visited the Show on the last day, and two more miserable objects could not be, the crests of both birds hanging over in front soaked with water. The second and third-prize birds were not soiled, and yet all drank from the same kind of water-vessel. This must speak for itself. Although the first-prize birds had the largest crests, they had certainly not the best-shaped ones, otherwise they would never have been in such a state; therefore, why should we take such birds as standards? You can easily see what keeps some of us from exhibiting.

As to Polish being hardy, I bred sixty-four last year, and never had a death except in the case of one which met with an accident. They feather-up very quickly, and require little care. My birds were hatched in May, and at just twelve weeks old I commenced killing-off the cockerels, and selling them for the table. The pullets began to lay one week after Christmas, and will continue to do so until moulting time without wanting to sit. Now, we cannot expect much more than this from any other variety we have.—A. Cruttenden, *Hayward's Heath.*

THE HAMBURGH COCK WITH PIN THRUST THROUGH HIS COMB.

We have had the following correspondence on this subject.

"Castle Yard, Knaresbrough, 1st March, 1872.

"Sir,—As solicitor and friend of Mr. Joseph Walker, of Birstwith, I ask for an opportunity of denying, on his part, any complicity in the placing the pin in the comb of the Hamburgh cock shown at Whitehaven, which has been so freely, and in some respects justly, commented upon in your Journal during the last three weeks. The bird was undoubtedly Mr. Walker's, but had only very lately been purchased by him; and I have now lying before me the letter of the person from whom the cock was purchased, in which he says, 'I am willing to confess that it was me, and not him that turned the bird. It was not done at his place at all; I do not like to see Mr. Walker wrongly blamed.'

"After this statement by the party committing the offence, and Mr. Walker's statement that he directed only the bird's head and feet to be be washed in the usual way, I trust that all remarks, so far as Mr. Walker is concerned, will be withdrawn; for anyone who knows him will feel sure that he would be the last person so cruelly to treat either bird or animal.

"I am, &c., Fred. Powell.

"The Editor of 'The Journal of Horticulture and Poultry Chronicle.'"

To this we replied—

"March 2, 1872.

"The Editors most readily will insert Mr. Powell's note, but they consider it would be much more satisfactory if the name of the cruel offender be published. He should be held up to the public as a warning. The Editors would publish the name in connection with Mr. Powell's note, and such publication is due to Mr. Walker, as it would satisfy the public more than the extract from the offender's note."

Mr. Powell's answer is this:—

"Castle Yard, Knaresbrough, 4th March, 1872.

"Whitehaven Show.

"Gentlemen,—I am sorry that I may not furnish you with the name of the offender against Mr. Joseph Walker and the public. Mr. Walker, erroneously I think, but out of consideration for the poor man's future welfare, promised him not to make his name public, but insisted upon his statement being made by himself in writing. If you require to see the letter I would ask for permission to send it to you, but it would have to be on the condition of the name not being made public.

"I am, &c., Fred. Powell.

"To the Editors of 'The Journal of Horticulture,' 171, Fleet Street, London."

We have not asked to see the letter, for we do not doubt its authenticity, but we consider that it is due to the public to publish the offender's name, that he might be punished by the aid of the Society for the Suppression of Cruelty to Animals. We refrain from other remarks.—Eds.

JUDGING AT POULTRY SHOWS.

The man who sends to a show his pen or two of birds, bred with what care and trouble he and his fellow fanciers alone know, and chosen from the numerous promising birds that have gone wrong and been killed or parted with, naturally wishes to win; but failing, his desire—nay, perhaps his sole reason for exhibiting, is to get the best possible opinion upon his birds, and to see or hear how they stand in comparison with others. With the present system of judging it is almost impossible for him to do this. He may go to the show, he may catch the much-badgered judge during the short time he remains to be blown-up (by the way, some do not remain at all), but this is a difficult thing to accomplish, and one that many object to on principle. Failing this, he is driven to use his own judgment, or that of sympathising friends, and the probability is that he returns home with the fixed idea that his birds ought to have done better; he can see they were not so good in some points as those that won, but then these are not perfect, and therefore in others he thinks them better, and striking a balance, with his natural bias thrown in as a makeweight, he declares that he has been hardly dealt with, though he has seldom anything tangible to prove. If he does not get to the show he sees by the catalogue that he is nowhere, or, worse, h.c., and cannot understand how it is.

I would suggest that this difficulty be got over by the adoption by the judges of numbered and perforated books, like those recommended for dog shows; the judge then makes his remarks on every pen (in most instances a few words are sufficient to condemn), and gives the secretary the torn-out half, which is numbered and copied from the other, which he retains for his own reference. The secretary prints the remarks after the exhibitor's name in a column set apart for that purpose in the catalogue, and the exhibitor would then be satisfied, I think. The sale of catalogues and entry of birds would greatly increase, and would thus enable poultry societies to engage more judges, which would be better than giving more time for judging; because judges could then be assigned to the classes they understand, for very few are good all round.

Thus, at the smaller shows the secretary and committee need not be so dependant on the large and professional exhibitors as to overlook trimming or other failings on their part, whilst visiting with a heavy hand the inexperienced clipping of the small man; nor need they allow these important personages to pen their own birds five minutes before the judges enter, whilst those of the smaller exhibitors have been shivering in the pens all night, and at that moment are standing with ruffled feathers and crops well distended, by the zealous feeder, who is determined they shall be well fed at "our show," whatever else happens. A little more printing, a little more trouble to the secretary (I do apologise to him, for I know he has always plenty of that commodity, and deserves all the gratitude we exhibitors can bestow), and another judge, would in most cases secure more equity.—Ginger Hackle.

COLCHESTER POULTRY SHOW.

(From another Reporter.)

The Committee, though few in number, were always at their post, and the most perfect order prevailed. Scarcely a pen even approaching inferiority of quality was to be met with, and it is long since we have seen a show with so few empty pens.

The Grey *Dorkings* were of a very high character, Mr. Lionel Patton taking with a grand well-shown pen, not only the first prize, but also the Dorking silver cup. The competition for this cup was great both among the Greys and also White Dorkings, the collection of the latter variety being particularly good. Lady Gwydyr's cup pen of Buff *Cochins*, and Mr. Horace Lingwood's Partridge-coloured, were such as would greatly add to the interest of any show, but the combined Cochin classes contained an entry of only eight pens. There was a large competition of Dark *Brahmas*, most of the pens receiving more or less favourable notice. The Light Brahmas were few, but generally good. The class of *Spanish* fowls was one of the most meritorious we have seen this season. *Hamburghs* in all the varieties were well shown, and seldom has a better collection been seen in this country. *Game* fowls were shown by many of our leading breeders; the silver cup for Game was awarded to a wonderfully perfect pair of Duckwings, though the competition on the part of the Black and Brown Reds pressed them closely. The well-known Red Pile cock of Mr. Samuel Mathews, that has, perhaps, received as many prizes as any Game cock existing, was completely thrown out, having become gouty in the feet, otherwise this old stager continues as hard in feather and clever in hand as can be desired. Game *Bantams* formed a couple of first-rate classes, Mr. Jeffries, of Ipswich, as usual in this neighbourhood, standing far ahead in the Black Reds, whilst the class for Duckwings was one of the gems of the Show. There was also a good entry in the class for Any other variety of Bantams; Silver-laced, White, and Black Bantams taking the prizes in the order named. A heavy entry of *French breeds* caused general attention. Crêve-Cœurs were first and second, and Houdans third. The Variety class for any breed not before named was unquestionably good; Malays, Sultans, and Cuckoo Rosy-combed Dorkings of great merit being the winners.

There was a good show of Rouen *Ducks*, but of Aylesburies only a single pen, the latter good enough, however, to obtain a first prize. The Variety Duck class contained many really valuable breeds, and the Selling classes (distinct prizes being offered for each sex) were a great success, containing many first-class birds.

Among the *Pigeons* were many of the best birds in the kingdom, some of them competing openly enough in the names of their owners, and some pens were lent for the occasion, a practice

now too general where collection silver cups are offered. Time has fully proved that collection cups, though ensuring a few noted first-class entries, have materially limited those of the general exhibitors, whose stock of Pigeons, perhaps, only embraces half-a-dozen breeds. We regret to state that in this division of the Show the most barefaced cases of trimming were found, and that, too, in considerable numbers; but, aided by a good light and sufficient time for judging, most, if not all, were properly exposed.

There was also a good and large collection of *Rabbits*; capital Lop-eared, Angora, and Himalayan being especially noteworthy.

Mr. E. Hewitt and Mr. Tegetmeier together judged the Game fowls, Game Bantams, and Rabbits; the whole of the other classes of poultry being judged by Mr. Hewitt. Mr. Tegetmeier awarded the prizes for Pigeons. We published the prize list last week.

FAKENHAM POULTRY SHOW.

The following awards were made at the Fakenham and West Norfolk Show, held on February 27th and 28th.

Dorkings (Coloured, except Silver-Grey).—1, Cup, and County Prize, E. W. Southwood, Fakenham. 2, F. C. Hart, Attleborough. *c*, Mrs. C. North, Rougham; W. Burrows, Diss; J. Norman, Colchester.

Dorkings (Any other Variety).—1, L. Wren, Lowestoft (Silver-Grey). 2 and *hc*, Rev. F. Tearle, Gazeley Vicarage, Newmarket (Cuckoo and White). County Prize, W. Woodhouse, King's Lynn (White). *c*, A. Taylor, Starston (Silver-Grey).

Cochins (Partridge and Buff).—1 and Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, Horace Lingwood, Needham Market. County Prize, T. W. Savory, Warham. *hc*, H. Lloyd, jun., Handsworth.

Cochins (Any other Variety).—1 and 2, R. S. S. Woodgate, Pembury, Tunbridge Wells (White). County Prize, Capt Bignold, Norwich (White).

Brahmas (Dark).—1, Lady Gwydyr. 2, Horace Lingwood. County Prize, W. Branford. *hc*, H. Dowsett, Pleshey, Chelmsford. *c*, W. Burrows; J. P. Case, Fakenham; Col. Cockburn, Bracondale, Norwich.

Brahmas (Light).—1, H. Dowsett. 2, P. Haines, Falgrave. County Prize, J. P. Case

Game (Brown and other Reds).—1 and Cup, H. M. Julian, Hull. 2 and *vhc*, J. Fletcher, Stonecleugh. County Prize, G. P. Rouse, Fakenham. *hc*, W. Rayner, Ipswich; G. P. Rouse. *c*, J. H. Salter, Tolleshunt D'Arcy; E. Branford; H. E. Martin, Southorpe.

Game (Any other Variety).—1 and County Prize, G. P. Tricker, Fakenham (Duckwing). 2, W. Rayner (Duckwing).

Game (Any Variety).—*Cock.*—1, H. E. Martin. 2, T. Wade, Stibbard (Brown Red).

Hamburghs (Gold and Silver-spangled).—1 and Cup, Ashton & Booth, Mottram. 2, R. H. Ashton, Mottram. County Prize, K. Middleton, Fakenham. *vhc*, W. K. Tickner, Ipswich; W. Groom, Ipswich. *c*, J. B. Lakeman; L. Wren; J. P. Case.

Hamburghs (Gold and Silver-pencilled).—1, J. Webster, Ca'ne, Lancashire. 2 W. K. Tickner. County Pri e, E. Farrer, jun., Swaffham.

Spanish.—1, 2, and County Prize, W. Woodhouse, King's Lynn. *c*, J. Norman, Colchester; Col. Cockburn.

Minorcas.—1 and Cup, County Prize, J. P. Case. 2, R. Wilkinson, Guildford. *c*, J. A. Miles, Fakenham.

Polands.—1, 2, County Prize, *vhc*, *hc*, W. K. Patrick, Lynn. *c*, Lady Gwydyr, Stoke Park, Ipswich.

French.—1 and Cup, C. H. Smith, Radcliffe, Notts (Crève-Cœur). 2, W. Burrows (Crève-Cœur). County Prize, Miss J. A. P. Leathes, Fakenham (Crève-Cœur). *vhc*, W. Dring, Faversham (Crève-Cœur). *hc*, — Fuller, Holt (Houdan). *c*, W. Cutlack, jun., Littleport (Houdan); Lord Hastings, Melton Constable (Houdan); J. de Laval Leiden, Diggleswade (Crève-Cœur); J. Franklin, Terrington, Lynn (Crève-Cœur).

Game Bantams (Brown and other Reds).—1 and Cup, W. Adams, Ipswich 2 and County Prize, G. Morling, Lynn. *hc*, W. Adams; A. Taylor. *c*, W. B. Jeffries; W. F. Addis, Fulwood.

Game Bantams (Any other Variety).—1 and *c*, Rev. F. Cooper, Ampney. Crucis (Duckwing). 2, W. Adams (Duckwing). County Prize, G. Morling (Duckwing).

Bantams (Any other Variety).—1, F. E. Thirtle, Lowestoft (Black). 2, Rev. F. Tearle, Gazeley Vicarage, Newmarket (White). County Prize, Mrs. North, Rougham Hall (White). *hc*, R. H. Ashton (Black); *c*, C. Woods, Harleston (White-booted).

Any other Distinct Variety.—1, H. Garbut, Whitby (Black Hamburghs). 2, Lady Gwydyr (Sultans). *c*, E. Hancock, Spalding (White Leghorn).

Table Fowls.—1, E. W. Southwood (Dorking). 2, W. Cu lack, jun. (Brahma). 3, H. Dowsett (Dorking).

Selling Class.—*Cock.*—1, C. Guy, Lynn. 2, Lady Gwydyr. 3, E. W. Southwood. 4, J. Wright, Lowestoft. *hc*, H. Plattin, Fakenham; W. Bunn, Kettlestone. *c*, H. Dowsett.

Selling Class.—*Hen.*—1, Lady Gwydyr. 2, Miss J. A. P. Leathes. 3, H. E. Martin. 4, H. Dowsett. *hc*, G. P. Tricker. *c*, E. P. Upcher, Bungay; J. P. Case.

Selling Class.—1, J. P Case. 2, E. W. Southwood. 3, Miss E. M. Hawker, Tunbridge Wells. 4, H. Thurlow, Bornham Market. *hc*, T. Spurr, King's Lynn; H. R. Plattin. *c*, H. Dowsett; E. W. Southwood.

Turkeys.—1 and *hc*, E. Arnold, Whitt'esford. 2 and County Prize, R. J. Kendle, Wenseenham. *c*, Mrs. C. North; Mrs. Reeve, Thetford.

Geese.—1 and County Prize, J. W. Sharman, Fakenham (White). 2, J. Hammond, Ball (Chinese). *hc*, J. W. Sharman (Sebastopol); J. Hammond (Canada).

Ducks (Aylesbury and Rouen).—1 and County Prize, W. Nicholson, Brisley Hall. 2, R. Rouse, Fakenham. *c*, A. Page, jun., Lowestoft; W. Burrows.

Ducks (Any other Variety).—1 and County Prize, A. T. Binny, Sennowe. 2, H. Savory. *hc*, R. H. Ashton. *c*, Rev. J. Richardson, Sandy Rectory (2).

PIGEONS.

Carriers.—1, W. Minson, St Ives. 2, S. Holroyd, Oldham. County Prize.—H. Thurlow. *c*, H. Yardley, Birmingham.

Pouters.—1, H. Pratt, Birmingham. 2 and *hc*, Mrs. Ladd, Calne. County Prize, H. Thurlow. *c*, H. Yardley.

Tumblers.—1 and County Prize, W. Woodhouse. 2, E. W. Southwood. *c*, E. H. Wallet, Norwich.
